

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

Considerations

RESPECTING THE

MANAGEMENT OF SIMPLE CONSTIPATION.

By SIR ANDREW CLARK, BART., M.D., F.R.S.,

ONE OF THE LECTURERS ON CLINICAL MEDICINE AT THE LONDON HOSPITAL.

THE untoward consequences of constipation are always considerable and sometimes serious; but greater than they—greater than the anæmia, the blood-poisoning, the headache, the nervousness, and the heart disorder which arise out of fæcal retention—are the untoward consequences of ignorant and unskilful domestic management.

For two days a patient has had no relief to the bowels. He has been travelling, or he has changed his diet, or his accustomed routine has been in some other way interrupted. The subject is seriously considered: in the light of an excited self-consciousness impending dangers are seen, and forthwith he determines to take "a dose." But the taking of doses is an inconvenient and a disagreeable procedure, and so it is settled that the dose shall be a good one—such a one as will speedily and effectually overcome the constipation and relieve the patient of his trouble. The dose is taken, the bowels (small, perhaps, as well as large) are emptied of their contents, the object of treatment has been achieved, and all for a time seems well. But the next day arrives, and there is no fresh movement of the bowels; even a second day passes, and they are still inactive. The patient is more uncomfortable than he was before he took his "dose." What is to be done? Matters cannot continue as they are. Plainly the medicine first employed has confined the bowels, and so another must be taken which shall be free from this disadvantage. The other is taken; again the bowels are freely moved, and a liquid, light-coloured, mucoid, and feculent discharge attests the success of the new endeavour. But the bowels fail to resume their periodical discharges; the patient becomes worse than ever; again he flies to artificial help for relief; again he is disappointed in recalling Nature to her own ways; and at last the bowels, robbed of their normal conditions of action and exhausted by frequent irritation, refuse to act at all except under the spur of strong aperients frequently repeated. With few exceptions, no person has passed through this experience and fallen under the tyranny of aperients without finding his life invaded by a pack of petty miseries which lower his health, vex his temper, and cripple his work. Now for the most part all these troublesome consequences of constipation may be avoided by attending to the conditions of healthy defecation. The chief of them requiring consideration at this time, and assuming the integrity of the nervo-muscular apparatus of the bowels, are plenty of solid and liquid digestible food, a fair amount of refuse matters in the colon, regard to the promptings of nature, daily solicitation at an appointed time, the co-operation of expectation and will, and contentment with a moderate discharge. I propose to discuss briefly each of these conditions.

1. Plenty of solid and fluid digestible food. People leading a sedentary or a society life become disposed to eat too fine foods, and to drink too little liquid. Among the results of such habits are a general want of nervo-muscular vigour, a deficiency of intestinal secretion, and an insufficient amount of refuse matter in the bowels to secure daily relief. To correct this without the help of drugs, coarse and irritating foods are taken. For a day or two perhaps they succeed; but after a time they provoke catarrhal irritation, and either increase the constipation or bring about lienteric diarrhœa. As a rule, it is a practical error to treat constipation by means of hard, indigestible, and irritating articles of food.

2. A moderately full colon is essential to the sufficient periodical discharge from the bowels. It is true that the ordinary peristaltic action of the bowels is automatic, and substantially independent of external stimulation; but it is, I think, equally true that for the stronger peristaltic action which, accompanied by inhibition of the associated lumbar centre and relaxation of the anal sphincter, issues in normal defecation, an external stimulus, the stimulus of an adequate amount of retained fæces, is necessary. If by an aperient or by any other means the colon is more or less completely emptied of its contents, defecation will be suspended until the colon becomes again more or less full; it cannot act independently of the appointed conditions of action; it cannot make bricks without straw.

3. Regard to the promptings of nature. When the lower part of the sigmoid flexure is full, sensory impulses are sent to the nervous centres, and these are responded to by discharges which not only excite vigorous peristalsis in the upper part of the colon and solicit the co-operation of the will, but tend to inhibit the lumbar centre and to bring about relaxation of the anal sphincter. The conditions of defecation are present, and it needs only a patient effort of will and concurrent expectation to originate and complete the operation. But when attention to these promptings of nature is denied they cease for the time; and although they recur and suffice for action, the denial, if often repeated, blunts the sensibilities of the parts concerned, deprives us of the normal intimations of the need for relief, and brings about a form of constipation difficult to cure.

4. Daily solicitation of nature at an appointed time. It has been found that for the great majority of people the most favourable, and also the most convenient, time for procuring relief to the bowels is after breakfast, and it is one of the greatest helps to sufficiency and regularity of action that the daily solicitation of nature should be practised at that time. In order that both solicitation and action should become developed into a habit, it is necessary that nature should not be listened to at any other than the appointed time. And in this precept there is no contradiction of the statement made in the previous paragraph; for it is not the temporary and exceptional denial of nature with the view of establishing a regular habit of defecation,—it is the repeated denial of nature with no such object in view which blunts the reflex sensibilities of the parts concerned and brings about an obstinate constipation.

5. The co-operation of expectation and will. Many persons seek relief to the bowels without taking any pains to secure success. With some persons, indeed, such pains are unnecessary. A certain automatism has been established; and it needs only time, place, and position to set it in successful motion. But in persons whose defecation is difficult, direct attention, expectation, and effort are essential, and when patiently practised seldom fail. The practice of slight alternate contraction and relaxation of the anal sphincter sometimes provokes exceptionally active peristalsis of the lower colon; and so, with concurrent effort, secures relief which could not otherwise be obtained.

6. Contentment with a moderate discharge. Ignorance of the average amount of fæces required for the daily healthy relief of the bowels is one of the main causes of constipation, the unnecessary use of aperients, and the evils that arise from both. For a man of average weight, consuming an average amount of food, the average amount of fæces ready for discharge in twenty-four hours is about five ounces. This should be formed, sufficiently aerated to float, and coherent. According as the cylinder is moist or dry it will measure from four to six inches in length. Now, many people expect to have a much more abundant discharge, and are dissatisfied or anxious if they do not get it. They complain of their insufficient relief, and take aperients to make it larger. For a day or two larger discharges are procured, but then, when the reserves of fæces are removed and the colon is empty, and the conditions of defecation no longer exist, more or less complete inaction of the bowels ensues, constipation (as it is here erroneously called) becomes confirmed, new and stronger aperients are had recourse to, and at last the patient falls into a pitiable condition of physical suffering and moral wretchedness. And from this condition there is no escape except through the complete suspension of aperients, the renewal of obedience to physiological laws, and a courageous patience in waiting upon Nature.

I will conclude these imperfect remarks by putting down as briefly as possible the instructions which I ask my pupils to give to their patients for the management of simple constipation:—1. On first waking in the morning, and also on going to bed at night, sip slowly from a quarter to half a pint of water, cold or hot. 2. On rising, take a cold or tepid sponge bath, followed by a brisk general toweling.

Digitized by Google

3. Clothe warmly and loosely; see that there is no constriction about the waist. 4. Take three simple but liberal meals daily; and, if desired, and it does not disagree, take also a slice of bread-and-butter and a cup of tea in the afternoon. When tea is used it should not be hot or strong, or infused over five minutes. Avoid pickles, spices, curries, salted or otherwise preserved provisions, pies, pastry, cheese, jams, dried fruits, nuts, all coarse, hard, and indigestible foods taken with a view of moving the bowels, strong tea, and much hot liquid of any kind, with meals. 5. Walk at least half an hour twice daily. 6. Avoid sitting and working long in such a position as will compress or constrict the bowels. 7. Solicit the action of the bowels every day after breakfast, and be patient in soliciting. If you fail in procuring relief one day, wait until the following day, when you will renew the solicitation at the appointed time. And if you fail the second day, you may, continuing the daily solicitation, wait until the fourth day, when assistance should be taken. The simplest and best will be a small enema of equal parts of olive oil and water. The action of this injection will be greatly helped by taking it with the hips raised, and by previously anointing the anus and the lower part of the rectum with vaseline or with oil. 8. If by the use of all these means you fail in establishing the habit of daily or of alternate daily action of the bowels, it may be necessary to take artificial help. And your object in doing this is not to produce a very copious dejection, or to provoke several smaller actions; your object is to coax or persuade the bowels to act after the manner of nature by the production of a moderate more or less solid formed discharge. Before having recourse to drugs, you may try, on waking in the morning, massage of the abdomen, practised from right to left along the course of the colon; and you may take at the two greater meals of the day a dessertspoonful or more of the best Lucca oil. It is rather a pleasant addition to potatoes or to green vegetables. 9. If the use of drugs is unavoidable, try the aloin pill. Take one half an hour before the last meal of the day, or just so much of one as will suffice to move the bowels in a natural way the next day after breakfast. If it should produce a very copious motion, or several small motions, the pill is not acting aright; only a fourth, or even less, should be taken for a dose. When the right dose has been found it may be taken daily, or on alternate days, until the habit of daily defecation is established. Then the dose of the pill should be slowly diminished, and eventually artificial help should be withdrawn. The aloin pill is thus composed: R Aloinæ, ½ gr.; extr. nucis vom., ½ gr.; ferri sulph., ½ gr.; pulv. myrrhæ, ½ gr.; saponis, ½ gr.; fiat pil. 1. If the fæces are dry and hard, and *if there is no special weakness of the heart*, half a grain of ipecacuan may be added to each pill. Should the action of the pill be preceded by griping and the character of the action be unequal, half a grain of fresh extract of belladonna will probably remove these disadvantages. If the aloin pill gripes, provokes the discharge of much mucus, or otherwise disagrees, substitute the fluid extract of cascara sagrada, and take from five to twenty drops in an ounce of water either on retiring to bed or before dinner. And when neither aloin nor cascara agrees, you may succeed by taking before the mid-day meal two or three grains each of dried carbonate of soda and powdered rhubarb.

The exact agent employed for the relief of constipation is of much less importance than its mode of operation. If, whatever the agent may be, it succeeds in producing after the manner of nature one moderate formed stool, it may be, if necessary, continued indefinitely without fear of injurious effects. But, treated upon physiological considerations, I have the belief that in the great majority of cases simple constipation may be successfully overcome without recourse to aperients.

GLASGOW SICK POOR AND PRIVATE NURSING ASSOCIATION.—The eleventh annual meeting of the supporters of this Association was held on the 24th ult., when it was reported that exclusive of midwifery cases the number of patients attended during the past year was 1621. The number of midwifery patients attended was 1438 and nurses had been engaged by 366 private families. The total ordinary expenditure for the year was £4040, the ordinary receipts amounting to £3371. Donations and legacies amounted to £307, and a balance of £635 is now due to the bank.

A Lecture
ON THE
SENSE OF HEARING.

Delivered before the British Association at Birmingham on September 6th, 1886,

BY WILLIAM RUTHERFORD, M.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF EDINBURGH.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—I am privileged this evening to address you on a subject that lies in the borderland between the realm of physics and that of consciousness. Our sense organs are the portals whereby the movements of the world around us find an entrance to our minds. We are so accustomed to the inflow of impressions through these organs; we are so familiar with light and darkness, with sunshine and shadow, with the colours and forms of objects; we are so accustomed to hear a multitude of sounds, and to readily apprehend the various meanings attached to them by our minds—that we constantly forget that but for the eye the world would be in darkness, and but for the ear nature would be silent.

That mode of motion which we term Light does not dispel the darkness until it falls on a living eye. That other mode of motion which we term Sound does not break the silence of nature until it enters a living ear. It is difficult to estimate how much we owe to the sense of sight for a revelation of the secrets of nature. It is still more difficult to form any just conception of what we owe to the sense of hearing. Far down in the scale of life, in long ages that are past, the first rudiment of an ear was developed; through its agency the vibrations of sound were enabled to influence the nervous system, and there to produce sound-sensations. As time went on, the organ became more highly developed, and no doubt more refined in its power of receiving and transmitting sound-impressions. At first there was no organ whereby the animal could produce sound as a mode of expression. But when an organ for sound-production was evolved, and when the animal became able to use that organ in suitable response to its various sensations of sound, the highest phase of brain action became possible. It needed only the higher development of the intellectual operations of the brain to make the perception of the different sound-sensations sufficiently refined to render possible the invention of language, with its manifold meanings and wonderful results. And at last it has come about, so closely are the impressions of sound associated with our mental operations, that we *think* in unspoken words.

I desire this evening to direct your attention specially to the sense of hearing—a subject full of interest, but at the same time so full of difficulty that I shall have to be careful lest I involve you in a maze of complex detail and baffle your perception of the main points. Those of you who have studied acoustics will have no difficulty in following my discourse. Therefore, I trust they will allow me to endeavour to carry with us those who may not be in a position so advantageous.

NATURE OF SOUND.

Let us in the first place attend to the nature of the physical agent that stimulates the organ of hearing. Strictly speaking, sound is a sensation produced in the brain by the activity of its nervous mechanism. But for convenience the term Sound is commonly applied to that mode of motion which enters our ears and throws the hearing apparatus into action. I shall use the word in that sense, and employ the term Sound-Sensation to indicate that state of consciousness which consists in hearing a sound. Sound is a wave motion, and therefore consists in vibration. Every sounding body is in a state of vibration. The vibration may be *simple* or *compound* in its nature, and it will be necessary for me at the outset to explain what is meant by simple and compound vibrations, otherwise you cannot understand the sense of hearing.

Simple Sound-Vibrations.—The motion of a pendulum is a familiar example of the sort of vibration that produces sound. The pendulum oscillates to and fro. When it swings from one side to the other and back again, it makes one

Digitized by Google

complete vibration. Its vibrations are repeated again and again in exactly the same period of time—they are *periodic*. The number of vibrations that occur in a unit of time—say in a minute—indicates the *frequency of vibration*. I can readily change the frequency of vibration by altering the length of the pendulum. If I shorten it, it vibrates more rapidly. The shorter I make it, the greater is the frequency of its oscillation. Observe that I can make the vibrations large or small without altering their period. If I throw the pendulum into motion with a gentle touch the *amplitude* of its vibration is small; if I use a greater force the amplitude of vibration is increased. But in both cases the frequency of vibration is the same. Every simple musical tone is due to simple pendulum-like vibrations of the air or other elastic medium. The *pitch* of the tone depends on *frequency*, its *loudness* depends on *amplitude*, of vibration. When a tuning-fork is thrown into motion, its elastic limbs oscillate to and fro like a pendulum, and throw the surrounding air into the invisible waves of sound. The molecules of the air oscillate forwards and backwards in the same period as the fork. When the two limbs fly apart they give a blow to the surrounding air that condenses it. When they swing towards each other the air is rarefied. And so the air is thrown into a series of concentric waves that continually expand, and gradually fade away as they travel to a distance. Each wave consists of a layer of condensed and one of rarefied air. You hear that the tuning-fork gives a musical tone. For the production of a musical tone two things are essential: 1. The vibrations must be strictly periodic; if they are not so, the result is not a musical tone, but a noise. 2. The vibrations must be sufficiently frequent. The fork which I have sounded gives 130½ vibrations in a second. The pitch of the tone is C in the bass clef. You cannot distinguish its individual vibrations; they are too rapid. But if a fork be made so long that it vibrates less frequently than sixteen times per second, one hears the pulses of sound separate and distinct. When the frequency of vibration is raised to sixteen per second, and still more clearly when it is raised to thirty or forty per second, the separate sensation due to each vibration lasts until the next appears, and so the sensation becomes continuous and the individual vibrations are no longer perceived. The pitch of a tone entirely depends on frequency of vibration. A very sensitive ear can distinguish an immense number of tones, varying from sixteen up to as many as 40,000 vibrations per second. In some persons the ear is so sensitive to frequency of vibration that in tones of ordinary pitch a difference of half a vibration in a second gives rise to a sensible difference in the sound-sensation. When a tuning-fork is properly sounded, its vibrations are simple, like those of a pendulum, and therefore produce a simple tone. The tone appears of lower pitch than is really the case, because no harmonics are present. If I attach a piece of brass-foil to the end of one of the limbs of the fork and place it in contact with a revolving cylinder covered with smoked paper, its vibrations are recorded and produce a wavy line similar to a vertical section of the surface of water in a state of wave motion. I have made an enlarged copy of one of the vibrations, and you see that it is a smooth curve, produced equally on both sides of an imaginary line of equilibrium, termed an abscissa. That is, then, the curve of a simple vibration.

Compound Sound-Vibrations.—Let us now attend to compound sound vibration. I sound two tuning-forks, the second of which vibrates twice as rapidly as the first. You hear two tones, and you recognise the second to be an octave above the first. We have a double sensation, evidently due to two sets of simple vibrations differing in frequency. Now, do the two sets of simple vibrations enter the ear? No, they are compounded into one vibration. You see from the drawing that when the two sets of vibrations are placed one upon another, the phases of movement are repeatedly in the opposite direction. But, as it is impossible for the same molecule of air to move in opposite directions at the same moment, the two vibrations must be compounded into one. When the two vibrations are in the same phase of movement they are added together, and the extent of the motion increased. On the other hand, when they are in the opposite phase they interfere with each, so that the resulting difference of motion has to be taken. The result is a vibration that differs in *form* from both of its constituent vibrations. It is still strictly periodic, but no longer pendular in form. Within the organ of hearing a compound vibration of that form produces an effect the same as if its two constituent simple vibrations acted independently. Now, suppose we take three forks with frequencies of vibrations in the relative proportion of 1, 2, 3. I sound them all at once, and again you hear a complex sound consisting of a fundamental tone with the octave above it, and with the fifth note of the scale above the second octave. The compound vibration differs in form from that of the previous case, and it produces a sensation of three tones, just as if the three sets of simple vibrations reached the ear independently. Suppose we were to take, say, eight tuning forks, having frequencies of vibration in the simple arithmetical relation of 1, 2, 3, 4, 5, 6, 7, 8. If we sounded them all at the same time we should get the highly complex vibration which I show you. The organ of hearing would treat that complex vibration as if it consisted of eight distinct series of simple vibrations. Eight different tones could be distinguished by a practised ear, and indeed by most ears if aided by resonators. Infinitely more complex are the vibrations produced by an orchestra with a chorus of human voices and solo singers associated. The mind fails in its effort to grasp the wave form of the flood of complex vibrations that pours into the ear at every moment. The highest and lowest tones are heard; the qualities of the notes produced by the strings, the wind instruments, and the voice are all discernible. The theory offered by Helmholtz in explanation of this wonderful property of the sense of hearing is that the terminations of the nerves in our ears can analyse complex vibrations. As they are supposed to do this by what is known as sympathetic vibration, I must explain what is meant by that term.

Sympathetic Vibration.—1. Of a tuning-fork; If I throw the air about a tuning-fork into vibrations of the same frequency as those which the fork can produce, the fork is thrown into feeble vibration. But it does not vibrate if the neighbouring tone has a higher or lower pitch than its own. 2. Of a string: If you lift the dampers from the strings of a piano by pressing down the loud pedal, and sound a note having the pitch of one of the strings, that string is thrown into sympathetic vibration and gives quite an audible note. If you produce a complex vibration with a number of tones having exactly the same pitch as some of the piano strings, they would analyse the compound vibration, and treat it as if it consisted of a distinct series of simple pendular vibrations, so that we should hear the piano strings giving forth notes of the same pitch as those which produced the compound vibration. A piano is better adapted than any other stringed instrument for doing this experiment, because of its large sounding box, which readily takes up the vibrations and communicates them to the strings. It is maintained by Helmholtz and others that in the ear every audible tone throws into sympathetic vibration one or more of the nerve terminations, and that all complex tones are analysed by them into simple pendular vibrations, which affect different nerve terminations according to their frequency of vibration. I shall presently show you reasons for doubting that theory.

THE ORGAN OF HEARING.

There is a general scheme applicable to all animals.

1. There is a *peripheral mechanism* to receive the sound vibrations and transform them into nerve impulses. In all animals that can hear, this peripheral apparatus consists of a modification of the epidermic cells that cover the integument. Each cell is a nucleated mass of protoplasm that has undergone some profound change whereby it has acquired the power of transforming sound vibrations into nerve impulses. The inner end of each of these auditory cells is connected with a nerve fibre, and from its outer free end there project one or more short, stiff, hair-like processes, termed Auditory Hairs. The hairs project into a watery fluid in the innermost part of the ear. The sound wave penetrates the fluid and causes the hairs to tremble. The sound vibrations caught up by the hairs pass into the auditory cells, and there, by some unknown mechanism, are transformed into nerve impulses.

2. The second part of the mechanism consists of nerve fibres that conduct the nerve impulses to the brain of a vertebrate, or to the cephalic ganglia of an invertebrate, animal.

3. The third part consists of sensory nerve cells in the brain, which are thrown into action by the arrival of impulses along the auditory nerve, and give rise to that state of consciousness termed Sensation. The position of

Digitized by Google

the centre for sound-sensation is definitely known in the ape's brain. Destruction of it on both sides of the brain produces total deafness. These three parts constitute the sensory mechanism for sound-sensation.

4. But we must add to this sensory mechanism other nerve cells in the brain concerned in perception—an intellectual act far higher than mere sensation, whereby the consciousness examines the various sensations of sound, and attaches to them various significations, with which they are afterwards associated. The centre for perception is probably placed in the front part of the brain.

FURTHER DETAILS REGARDING THE PERIPHERAL MECHANISM.

I must now state some further details regarding the peripheral mechanism of the organ of hearing.

The Invertebrate Ear.—A hearing apparatus is found in the Medusæ, and in all animals above them. Stated briefly, its most general condition is that of a minute sac with a membranous wall. The sac is full of fluid, and lined by a layer of ectodermic cells, some of them modified into hair cells. The auditory hairs may project free into the fluid, but that is rare. Most commonly they project into a calcareous mass, termed an Otolith or Earstone. The otolith consists of about 75 per cent. of lime salts in the form of grains or crystals, held together by a small amount of mucous jelly. The effect of the otolith is not well understood. It has been thought that the hard calcareous particles may rattle against the hairs, like the shingle on the sea beach when the wave breaks over it. If that be so, we may reasonably suppose that the periodic vibrations of a musical tone must be changed into indefinite vibrations, and produce nothing but noise. It may be, however, that there is no rattling of the particles, and that the otolith and hairs move to and fro as one mass when the sound wave reaches them. If that be so, the mechanism is probably not advantageous for the hearing of faint sounds, because it is difficult to throw a heavy mass into movement. Otolith sacs are found in the ear of every vertebrate, but when in the vertebrate series the ear becomes an organ for the delicate appreciation of musical sounds there is a great development of hair cells without any otolith in connexion with them.

The Vertebrate Ear.—Let us turn to the structure of the ear in the vertebrate series of animals. In the lowest group of fishes the otolith sac has in connexion with it a membranous semicircular canal, with a swelling at each end of it containing hair cells with nerves passing to them. In the higher fishes, and in all other vertebrates, three semicircular canals are developed in each ear. Each canal has a swelling at one end of it containing hair cells without any otolith. These canals are nearly always placed in the planes of a cube—that is to say, in the three dimensions of space,—and are now supposed to be peripheral organs, not of the sense of hearing, but of a sense that renders us acquainted with the movements of the head, and so helps us to maintain the equilibrium of the body. The otolith sac becomes divided into two: one termed the Utricle, connected with the semicircular canals; the other termed the Saccule, from which a single membranous canal, the cochlear canal, becomes developed in reptiles, birds, and most of all in mammals. In reptiles and birds it is short and nearly straight. In mammals it is much longer, and coiled up like a snail's shell. Hence the term Cochlea. The cochlear canal contains an immense number of hair cells, with a multitude of nerve fibres passing to them. The membranous sacs and canals that I have mentioned constitute the membranous labyrinth, and are found in the innermost part of the ear. They are all filled by a watery fluid, and nearly surrounded by another watery fluid enclosed in the bony labyrinth. The sound waves are conveyed to the outer fluid of the labyrinth. They then pass through the membranous walls of the otolith sacs and the cochlear canal into the fluid within them, from which they are caught up by the hair cells.

Much as I should like to indicate to you the structure and action of the beautiful mechanism by which sound is conducted to the labyrinth, the shortness of the time at my disposal compels me to limit your attention to the cochlear canal which contains the hair cells that enable us to appreciate musical sounds. It is a canal of somewhat triangular shape when cut across. Two sides of the triangle are bounded by thin membranes that are traversed by the sound waves. The chief of these two membranes is termed the Basilar Membrane. It is composed of fibres of connective tissue, that stretch across the general cavity of the cochlea, and are continuous at both ends with the periosteum that lines it. The membrane somewhat resembles a slender suspension-bridge stretching across a ravine. This cochlear suspension-bridge, if I may so term it, extends through the whole length of the cochlea in mammals, but in birds it is wanting at the upper or closed end of the tube. It is covered on both surfaces by epithelial cells. Very many of those on the upper surface are hair cells, with ordinary or somewhat modified epithelial cells placed between them to support them in their places. There is an immense number of these hair cells. In the cochlea of the cat four rows of them run the whole length of the cochlear canal. In the human subject there are five or six rows of them, and the total number of the cells is estimated at about 15,000. These hair cells of the cochlea seem placed in a position of advantage, inasmuch as they are supported on a membrane that can vibrate with the sound wave. It is otherwise with the hair cells of the otolith sacs. They are planted on a membrane that is fixed in the periosteum lining the bony wall of the labyrinth. Immediately over the free ends of the hair cells there is a thin covering membrane, the use of which it is difficult to comprehend. During life it is probably soft, but when the soft parts of the cochlea have been hardened to permit of thin slices being made for microscopical observation, the membrane has a laminated appearance, with a distinct hem at its lower surface. In other respects it is homogeneous. One margin of it is always firmly attached to the periosteum at the inner angle of the cochlear canal. The other margin is usually free and turned up like a scroll. But it may be that, in a cochlea which has not been injured by slicing it with a knife, the outer margin dips down, and is attached to the supporting cells outside the hair cells. It is also difficult to say what may be the relation of this covering membrane to the hairs of the auditory cells. It is not definitely known whether the ends of the hairs are free, or touch the covering membrane, or project into it. I have never seen them projecting into it, nor have I seen any hairs torn off and adhering to the membrane. It must be admitted that the function of the covering membrane is quite obscure, and must remain so until we know its precise position with reference to the hairs. It has been suggested that its function is to damp the vibrations of the hairs, and so prevent their vibrating too long. But it may be supposed that structures so excessively short as these hairs need no damping apparatus. However that may be, the sound-wave comes into the cochlear canal on the side of this covering membrane, and travels through it to reach the auditory hairs.

THE ACTION OF THE COCHLEA.

I have now, in the last place, to criticise the present accepted theory of the action of the cochlea in the reception of sound, to point out its shortcomings, and to offer for your consideration a new theory. Helmholtz, in his great work on the "Sensations of Tone," supports the theory that the nerve terminations in the cochlea are affected by sound, on the principle of sympathetic vibration; that is to say, there is a finely graduated series of nerve terminations that individually respond to tones of a pitch varying from sixteen to many thousands of vibrations in a second. That theory is based on the analogy of the sympathetic vibration of tuning-forks and strings. No doubt it has been shown by Professor Hensen of Kiel that the free auditory hairs of some crustaceans vary in length, and that when he sounded different notes with a horn some hairs vibrated more than others to particular notes; he admits, however, that when he sounded any note very loudly all the hairs vibrated. But when we turn to the cochlear hair cells, especially those of mammals, we find that the hairs are all nearly of the same length and all exceedingly short. It would take from 120 to 220 of them placed end to end to make the breadth of one millimetre. The shaft of an ordinary pin is just about the breadth of a millimetre. The hairs are therefore exceedingly short, and their variation in length so trivial that no one has ever suggested that the different hairs can be expected to make a selective response to sounds of different pitch. But in all animals auditory hairs are the recipients of sound vibrations. In the organ of taste also, delicate hairs at the free ends of epithelial cells are the parts impressed by molecular motion. Why, then, is the theory still maintained, although the condition of the auditory hairs gives no countenance to it? Hensen has endeavoured to show that, as the fibres of the basilar membrane slightly increase in length from the

Digitized by Google

base to the apex of the cochlea, they answer the conditions required for the sympathetic responses to tones of different pitch. But the fibres are at most very short, and their variation in length very slight. They vary from one-fifth to rather more than a third of a millimetre—that is to say, it would take from three to five of them put end to end to make the breadth of a common pin; and yet within the limits of dimensions so minute we are expected to find a series of vibrating bodies that with unfailing precision select particular vibrations, varying from 16 to 40,000 in a second. But the fibres of the basilar membrane are regarded by no one as the terminations of nerves, and although an attempt has been made to show how the vibrations of certain fibres may be communicated to certain hair cells, the explanation is so far-fetched that I need not trouble you with it. I am convinced that this theory of sound analysis in the cochlea, or in any other part of the peripheral mechanism of the ear, must be abandoned. But even supposing the theory a feasible one, see what would be the result of its acceptance. Imagine a great number of sensory nerve cells, all in a row, for the sake of simplicity, with a nerve fibre going from each one of them to a hair cell in the cochlea. A tone of say 100 vibrations per second arrives at the hair cells and stimulates its particular cell. Its nerve is then stimulated. A particular sensory cell is in turn excited, and we hear a tone of a low pitch. On this theory, the pitch of the tone we hear is not due to 100 impulses per second coming along the nerve to the sensory cell. Not at all; that is no part of the theory. It is the excitement of a particular nerve cell or group of cells that is supposed to give the sensation of this particular tone. Suppose a tone of 101 vibrations per second entering the ear: we have the sensation of a tone of higher pitch than the other. On this theory, the sensation of this higher tone is supposed to be due to the stimulation of another sensory nerve cell. So that for every different sensation of pitch, even although the exciting cause differ only by one, or even half a vibration, there must be a different sensory cell in the brain to give it.

Let us see how the theory of *concord* and *discord* fares on this theory. I sound two organ pipes tuned to give the same note. You hear an even flow of sound. I throw them out of tune by causing the one to vibrate a little more rapidly than the other. The even flow of sound is lost, and you hear a harsh discord due to alternate risings and fallings in the loudness of the sound—commonly termed Beats. The beats result from the action of the two sets of sound waves upon each other. Suppose we have two sets of waves started at the same moment, one having the frequency of 100, the other of 101 per second. The crests, so to speak, of the two sets of waves will coincide only once in a second, and give a flash of sound. At all other periods in the second the two sets of waves interfere with each other and diminish the sound; therefore once every second the loudness of the sound would rise from a minimum to a maximum, fall again to a minimum, and so produce one beat per second. The absence of beats is essential for the concord of sound. If I sound three forks whose vibrations are in the proportion of 4, 5, 6, we get the common chord of Do, Mi, Sol in the major mode. We recognise these three tones individually; yet they blend, and the compound vibration flows smoothly on without beats, and is therefore harmonious and agreeable. It is admitted that this agreeable sensation of harmony is entirely due to the relative numbers of the vibrations. Its cause is strictly physical and mathematically precise.

But see what is supposed to happen in the organ of hearing on the theory I am criticising. The complex vibration is supposed to be analysed in the ear and the vibrations of Do, Mi, Sol are caught up by at least three different fibres of the basilar membrane and transferred to at least three different hair cells. The nerve impulses are sent along at least three nerve fibres to the brain, and at least three sensory cells are excited there, and so give the three sensations of Do, Mi, Sol. But the three sensations are blended into the compound sensation of a harmony. How and where can they blend? No doubt the sensory cells send their impulses to the common centre for perception, and we can imagine the blending taking place there. *But if the motions in the three sensory nerve cells are eventually to be blended, it seems unnecessary that the already blended sound-vibrations should have been analysed in the cochlea.* And if the sensation of a harmony so clearly depends on the relative number of vibrations, it seems necessary to suppose that in the three sets of nerve fibres there are vibrations of nerve molecules at frequencies in the proportion of 4, 5, 6, and that these pass to the sensorium, and are eventually blended into a harmonious sensation. If this be not so, then we have really received no explanation of the *physiological causes* of harmony and discord.

This theory of sound-sensation, then, is so full of difficulty when applied to the peripheral mechanism in the ear, and so unsatisfactory when we pursue it into the brain, and it seems so hopeless to adapt it to the facts, that I think it must be abandoned. But before I propose another theory, I would pay a humble but sincere tribute to the genius of Helmholtz. His magnificent services to science have long since placed his name amongst those of the immortals. His theory of sound-sensation may be faulty, but that can never tarnish the splendour of his many wonderful contributions to the progress of scientific knowledge.

A NEW THEORY OF THE SENSE OF HEARING.

Some five years ago it struck me that the case of the telephone may throw light on these difficulties regarding the sense of hearing. In the telephone there is a thin plate of iron placed near the end of a permanent steel magnet. A bobbin of thin copper wire is coiled round the end of the magnet nearest the plate, and is connected with a bobbin of wire around the magnet of a second telephone in every respect similar to the first. When sound-waves fall on the plate of the transmitting telephone it vibrates. The vibrations of the iron near the magnet affect the magnetism, and so induce in the wire currents of electricity whose frequency and amplitude correspond to those of the vibrations of the iron plate induced by the sound. The currents travel to the receiving telephone and induce oscillations of its magnetism, which in turn cause its iron plate to vibrate and produce sounds similar to those communicated to the first telephone. There is no analysis of the sound-waves. The transmitting telephone takes up simple or complex vibrations. The harmonies of an orchestra may fall upon it, and it does not fail to convert the complex sound-vibrations into electrical vibrations, and these again into the complex sound of the orchestra in the receiving telephone. It is, indeed, one of the most wonderful inventions of recent times. Can it throw light on the sense of hearing?

The theory which I have to propose may be termed the Telephone Theory of the Sense of Hearing. The theory is that the cochlea does not act on the principle of sympathetic vibration, but that the hairs of all its auditory cells vibrate to every tone, just as the drum of the ear does; that there is no analysis of complex vibrations in the cochlea or elsewhere in the peripheral mechanism of the ear; that the hair cells transform sound-vibrations into nerve-vibrations similar in frequency and amplitude to the sound-vibrations; that simple and complex vibrations of nerve-molecules arrive in the sensory cells of the brain, and there produce, not sound again of course, but the sensations of sound, the nature of which depends not upon the stimulation of different sensory cells, but on the frequency, amplitude, and form of the vibrations coming into the cells, probably through all the fibres of the auditory nerve. On such a theory the physical cause of harmony and discord is carried into the brain, and the mathematical principles of acoustics find an entrance into the obscure region of consciousness. Now if nerve energy were only electricity, that theory would probably be accepted at once. But nerve motion is very sluggish when compared with electricity.

I have kept this theory back for five years, because I felt I had no evidence of the possibility of sending a rapid succession of vibrations along a nerve. It cost me a good deal of thought and experimental observation to find the evidence I required. If we give to a motor nerve of a frog or rabbit ten instantaneous shocks of induced electricity in a second, ten impulses will pass along the nerve to the muscle, and produce ten distinct contractions in the same period. If we send forty impulses along the nerve, we get, not forty contractions of the muscle, but a single continuous contraction, because the several contractions are fused together. Now, if we listen to the muscle so stimulated, we hear a musical note having the pitch of forty vibrations per second. Each sound-vibration results from the sudden shock of chemical discharge due to the arrival of each nerve impulse in the muscular substance. If we stimulate the nerve, say, 200 times per second, by causing a tuning-fork to make and break the primary circuit of an induction machine, and so send 200 shocks per

Digitized by Google

second into the nerve, the pitch of the note in the muscle exactly corresponds. It has the same pitch as the fork. I experimented in this way, and eventually found that I could send as many as 352 impulses per second along the nerve of a rabbit and get a note from the muscle of the pitch of 352 vibrations per second—that is, a note of the pitch of F in the lowest space of the treble clef. But when I tried by more rapid stimulation of the nerve to get a higher note from the muscle, I failed; there was nothing but a noise heard. That a low rumbling sound is produced by a contracting muscle is known to every physiologist. You can hear it if you firmly clench the jaws during the stillness of night, when other sounds are hushed. It is a sound of very low pitch due to vibrations certainly below 40—perhaps not more than 10 or 12 per second. There is therefore nothing new in my statement that a note may be heard in a muscle; the new point is that the pitch of the note may be increased by a more rapid stimulation of the nerve, and that as many as 352 impulses may be sent along a nerve and retain their individuality so sharply that they can produce a note in a muscle having a pitch number of 352. That fact will give support to a vibrational theory of nerve energy.

Now, am I to conclude that, because I failed to get a higher note than one of 352 vibrations from the muscle, it is not possible to send more than 352 vibrations per second along a nerve? By no means; the fibres of a muscle are very different from those of a nerve, and also very different from nerve cells. The molecules in both of them can probably vibrate far more rapidly than 352 times per second.

I have therefore directly proved that vibrations of the same frequency as all the lower tones of the scale, from the lower F of the treble clef downwards, can be transmitted by a nerve. A short time ago it occurred to me that the note produced by the wing of an insect furnishes a simpler proof of the possibility of transmitting a rapid series of impulses along a nerve. The wing of the humble-bee produces the note F in the lowest space of the treble clef. It gives, therefore, 352 complete vibrations in a second. Every downward motion of the wing doubtless results from an impulse sent along the nerve to the muscles that lowers the wing. Therefore we may conclude that about 352 impulses per second traverse the motor nerves of the humble-bee's wing during flight. In the honey-bee the note of the wing is A in the treble clef—that is, two notes higher than in the humble-bee, so that 460 impulses appear to pass along its motor nerves in a second. In a human motor nerve the impulses transmitted by it during voluntary effort are not more than 10 or 12 per second (Schaefer). I have therefore some substantial evidence in support of my theory of sound-sensation. And I cannot but think that the evidence in favour of it will increase. I do not wish you to suppose that on my theory of hearing difficulties disappear; far from it. I merely assert that the difficulties which seem insurmountable on the theory of Helmholtz are diminished by the theory which I have submitted. Should my theory of the sense of hearing find acceptance, it will lead to a reconstitution of theories regarding the other sense organs.

Harveian Lectures
ON
CANCER OF THE UTERUS.

BY J. WILLIAMS, M.D. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE I.

GENTLEMEN,—No apology is needed for making cancer of the uterus the subject of the Harveian Lectures; the disease has been, and always will be, one of great interest to the practitioner and the pathologist. The frequency with which it is met, its irresistible progress, the horrible sufferings which it entails upon its victims, the utter helplessness of medicine in its presence, and its fatal character, all alike join in demanding a careful study of its insidious onset and destructive habits. I should have liked to have reviewed the history of cancer, to have summarised the views which have been held with regard to it, and the various methods of treatment which have been suggested and practised with a view to its cure and the relief of the symptoms and sufferings caused by it, and to have traced the progression and retrogression of knowledge with reference to it; but time will not permit me this indulgence. I must be satisfied with endeavouring to depict to you the present state of scientific knowledge with regard to the disease. To do this I must invite your attention more particularly to the early stages of cancer—the curable stages, if there be any such—before the diseased process has passed beyond the limits of the uterus itself.

Before beginning the consideration of the subject we must have a clear and exact knowledge of what we mean by cancer; and to avoid misunderstanding I will explain the meaning I shall attach to the word. I adopt that meaning which is given to it by one school of pathologists, and which appears to me to be the most reasonable, and the most likely to favour the growth of our knowledge of malignant diseases. Cancer, then, is a new growth possessing malignant properties—that is, it possesses the power of invading neighbouring tissues, and of reproducing itself in the form of secondary growths in other and distant parts. It is not so very long—not more than forty years—since the term was applied to growths which are now known to be devoid of any malignant properties. Fibroid tumours of the uterus were then regarded as cancer, but without good reason. They possess none of the peculiar properties, anatomical or clinical, which are possessed by the more serious affection. The distinction between growths which possess malignant properties and those not possessing them is to be made by two kinds of observations—those made at the bedside and those made at the laboratory. Clinical observation alone is sufficient to decide whether a growth be malignant or not, provided one condition is fulfilled—viz., that time is not stinted. Weeks or months of watching will solve the question; but examination of the growth by means of the microscope enables us to solve it at once. All malignant growths, however, are not cancer, and clinical observation, as a rule, is not equal to making the distinction between the different kinds of malignant disease. Here the work of the laboratory, and, above all, that done by the help of the microscope, comes to our aid. It is by the microscope alone that we are enabled to distinguish them. Progress in our knowledge of malignant disease in the future will depend in a great degree upon microscopic or laboratory work. Its revelations must form the basis of the classification of our clinical observations. During the early stages of cancer, or of other malignant growths, the microscope, I believe, will enable us to recognise and make sure of the disease long before clinical examination; and it is by no means improbable that in any given case, even in the most advanced stages of cancer, the structures revealed by the microscope will empower us to read back the whole of its past history, when clinical examination and observation of the living growth have failed to cast a ray of light upon the previous progress of the disease.

The varieties of malignant disease which affect the uterus are three—namely, sarcoma, carcinoma, and adenoma. Sarcoma and carcinoma are always malignant; adenoma often, but not always, but perhaps always in the uterus. Sarcoma is a growth of the connective tissue type. "It originates in a structure of the connective tissue group, and grows from its constituent cells. Carcinoma and adenoma, on the other hand, contain epithelial elements, and these elements are the structures which give its special characters to the class. All these tumours consist of epithelial cells on the one hand, and of vascular connective tissue on the other. The latter tissue goes to form the framework or stroma in which the epithelial elements are embedded. Some of these are built exactly on the plan of some particular gland; the new-formed tissue corresponds to a definite glandular type. These are called adenomata. Another group never reaches this perfection; they exhibit, as it were, only the first stage of the gland-making process. Epithelium and fibrous tissue interpenetrate each other in an inchoate way. The process is never carried higher. By the multiplication of epithelial cells we have produced nests and clusters and strings of cells, and these are embedded in connective tissue whose elements are likewise multiplying. The result is a neoplasm consisting of a fibrous network or framework, in the meshes of which are lodged a multitude of variously shaped epithelial cells. But there is no orderly arrangement of these epithelial cells. In the adenomata they tend to clothe the alveoli in

Digitized by Google

a regular way, leaving open a central lumen in the acinus of a gland." (Ziegler.) It might be thought that with anatomical characters apparently so distinctive there would be no difficulty in distinguishing between the different kinds of malignant growths. Such, however, is not always the case, because growths of the connective tissue type or sarcomata sometimes assume an alveolar form, and their alveoli contain groups of cells which are indistinguishable by the microscope from epithelial cells; so that, judging by anatomical evidence alone, a sarcoma may be mistaken for a carcinoma, and a carcinoma for a sarcoma. This fact has led to different views with regard to the origin of cancer. Some authorities maintain that it originates only in tissues in which epithelium is present, while others hold that it originates in connective tissue in the absence of epithelium. I will not enter upon a discussion of these views, for the definition of cancer which I adopt obviates the necessity for it. I define cancer not anatomically only, but anatomically and genetically—that is, cancer is an alveolar new growth containing epithelial structures which have originated from previously existing epithelium. In this sense only will the term be used in these lectures.

Before classifying and describing the various forms of cancer as they affect the uterus, we must enumerate the parts into which the organ is divided, and note their limits. The uterus is divided into three parts, according mainly to the character of the epithelium and of the glands met with in each part. The first is the vaginal portion. This is the part of the uterus exposed in the vagina. It is bounded below by the stratified epithelium covering the vaginal surface of the cervix, and above by a line drawn from the external orifice, or a little above that point, to the insertion of the vagina. The discovery of the position of the original external orifice is, however, in many cases difficult, and sometimes impossible. The position of it alters, and its characters are liable to be destroyed by tears and by "erosions." The position of the external orifice is that place where the squamous epithelium covering the cervix ends and the transitional begins. This transitional epithelium disappears in many cases, and is replaced by a glandular "erosion," which is covered by columnar epithelium, and the columnar epithelium meets the squamous of the portion without the intercalation of the transitional, and may even extend over an area which in health was covered by squamous epithelium. Such surfaces contain glands, and present the characters of the mucous membrane of the canal of the cervix. They should, I think, be treated as parts of the mucous membrane of the cervical canal, and therefore I shall limit the term vaginal portion to that part of the cervix which is covered by epithelium of the squamous and transitional kinds. This will give the inner end of the line limiting the portio vaginalis above, a little within the cervical canal, in cases of small narrow os externum; and somewhere on the surface exposed to the vagina, in cases of "erosion" or of lacerations of the cervix with eversion. This portio vaginalis is really a cap of stratified epithelium resembling a tailor's thimble, which fits on the lower end of the cervix proper.

The next part is the cervix. It is limited below by the portio vaginalis, above by a plane drawn transversely through the inner orifice, or more accurately through that point where the follicles characteristic of the mucous membrane of the cervix end and the tubular glands characteristic of the decidua begin. The portion of the organ above this plane constitutes the body and fundus of the uterus. This division of the uterus with the boundaries mentioned is of importance because cancer may begin in any one of them, and it appears that the disease generally presents different characters, runs a different course, and is amenable to treatment in different degrees, according as it begins in one or other of these divisions. To trace the life history of cancer has always been found to be a difficult task, and the difficulty has arisen from two causes:—Firstly, because cases rarely come under our notice at a period sufficiently early for observations of the first beginnings of the disease to be made; they come at an advanced stage, when it has become impossible to guess even at their earlier course; from this time on to its certain and uniform termination we possess ample knowledge of the disease, of a kind. The second cause of difficulty is that when cases are examined early their true nature is overlooked. I believe this to occur much oftener than is generally supposed. The result is a very scanty knowledge of the natural history of cancer, with very imperfect descriptions of it.

Cancer is usually classified into scirrhus, encephaloid, medullary, and epithelioma. This classification has no value, and little meaning, as far as the uterus is concerned. Names have also been given to the disease descriptive of the morphology of the new growth—such as cauliflower excrescence, polypoid, diffuse cancer, &c.; but no classification of cancer of the uterus according to its structure has been made with the exception of that made by Ruge and Veit. I shall not refer again to the usual division into scirrhus, encephaloid, &c., but shall describe the structures met with in cancers of the several parts of the uterus, and then I shall arrange cancers according to the structures we shall have met with. The observation of structure alone is not sufficient. We want to trace the course of the disease, the lines along which it moves, discover the tissues which form its favourite pasture—in short, to read its history. When we shall have done this, we may hope to know something about it, and to be in a position to estimate, in some degree at least, the value of any proposed method of treatment. Cancer of any one part of the uterus is cancer which has originated in that part, and not cancer which has invaded it from some other source. Now cancer may begin in the vaginal portion, in the cervix, or in the body of the uterus, and these I shall describe by examples of each. Cancer of the vaginal portion and of the cervix have been described together until Ruge and Veit published their work on Cancer of the Uterus—a work which marks an epoch in the study of the disease.

CANCER OF THE PORTIO VAGINALIS.

Cancer of the vaginal portion begins in the stratified epithelium on the vaginal surface, or in the transitional epithelium at the os externum. Cancer involving this part is common enough; indeed, most of the cases of so-called cancer of the cervix are instances of cancer involving this part, but not originating in it; the instances, however, in which cancer had originated in the portio, and in which the disease was observed at an early period, are very few. Ruge and Veit, to whose work I have already referred, and to which I shall have to refer again, describe twenty-one cases of what they consider cancer of the portio. Among them are included glandular cancers, originating in erosions, as well as certain malignant growths, originating in the connective tissue—which they include among cancers. The glandular cancers I shall range among cancers of the cervix proper, and the connective tissue growths among sarcomata. If we exclude these from among Ruge and Veit's cases, we find they have seen no case of cancer of the portio, or only one surrounded by doubt. Of cancer of the vaginal portion I have observed eight cases only, and have seen specimens from several others; and it is upon these cases mainly will depend the account I have to offer of cancer of this part. I know of no better way of giving you an idea of the disease than by describing typical cases as fully as possible.

CASE 1.—This case presented perhaps the earliest instance of cancer which can be distinguished with certainty. It was a patient in whom the cervix had been divided into three lobes by laceration. She improved greatly under treatment; so much so, indeed, that she complained of no uterine symptoms at all. Two of the lobes into which the cervix had been lacerated assumed a healthy appearance, but the third remained in an unsatisfactory condition, and I cannot tell you what was unsatisfactory about it. It was not hard, it was not unduly red, it did not bleed on digital examination, it did not enlarge, and yet it looked vicious; and the vicious character seemed to be expressed by a slightly livid appearance of the part only, and scarcely that even. But I will read brief notes of the case to you.

The patient was thirty years of age, married, and had had two children and one miscarriage. She was admitted into University College Hospital on Jan. 12th, 1886. She knew of no cause for her illness; but she began to bleed in February, 1884, when she was two months pregnant: she had several irregular floodings until May, when she miscarried, and was laid up afterwards for six weeks with what she called "rheumatism" in her foot and elbow. She afterwards improved, but since the miscarriage menstruation has been irregular, returning at too short intervals, and lasting longer than usual. She did not feel any the worse for it until eight or nine months ago, when the flow began to be so excessive and prolonged as to give her only one week clear. Her strength and general health failing, she sought advice. She had lost flesh of late. She said she had sore-throat and loss of hair in 1884, but no rash. She began to menstruate at twelve years of age; was regular every four

Digitized by Google

weeks, the flow lasting a week in considerable quantity, but without pain. She was married at twenty-two. Her second labour was accompanied by a flooding, but she made a good recovery. No family history of cancer was obtained. Her mother died of consumption.

The cervix was low in the pelvis; it was torn on the right side and on the left, and deeply through the anterior lip; there was considerable eversion; there were granules on the everted surface like enlarged and closed follicles. The body of the uterus was anteverted and normal. Through the speculum the vaginal portion appeared pale and covered by squamous epithelium; the left three-quarters of the anterior lip was everted, and bled when touched. The right quarter formed a projection like a nipple; the posterior lip was everted and paler than the everted portion of the anterior. It did not bleed on examination. There was a considerable quantity of muco-purulent discharge on the surface. Temperature 98·4° to 100° F.

By the application of a solution of sulphate of copper to the cervix and canal of the body, menstruation became normal, the discharge ceased, and the lips of the cervix assumed a healthy appearance, with the exception of the left portion of the anterior lip. In July this portion of the anterior lip was removed for reasons already given. This was examined under the microscope, and a very interesting state of things was found. Beginning our examination on the vaginal surface, we found the stratified epithelium intact and somewhat thickened. At the reflexion of the vagina, however, the deeper layers of the epithelium sent processes into the subjacent tissue, and beyond this, on the surface of the portio, several such processes were met with; these processes branched, and some entered glands, which were evidently the glands of an erosion; further on were found swellings of the deeper epithelial layers and glands lying in them; glands again running more or less parallel to the surface, branched or simple; then a gland, one side of which was invaded by squamous epithelium, the rest being lined by epithelium of the columnar form; then irregular thickenings of the deeper strata of the epithelium of the surface, running into and between the glands; the cells of such glands were partially replaced by the squamous variety and were rapidly proliferating; then we came upon a part of the cervix in which the papillæ were everywhere enlarged, and beneath which were found numerous glands. The cervical tissue near the whole of the surface I have described was everywhere infiltrated with small cells, but this was not seen under those portions over which the superficial epithelium was healthy. In some places the glands were filled with secretion, and some were changed into closed follicles. This is the earliest condition of undoubted cancer of the portio which I have met with, and it is the earliest condition which is recognisable as cancer. It presented no symptom, and was discovered accidentally. Its nature was not recognised with certainty, but was held in suspicion.

CASE 2.—In this case there was no difficulty in coming to the conclusion that the disease was cancer, for there was a new growth which progressed so rapidly as to leave no doubt as to its nature. It was in an early stage, but it differed in several respects from the one I have just related. In the first case cancerous processes appeared to enter the cervix from several points on the portio. In the case we deal with now there was a distinct papillary growth situated at the external orifice on the posterior lip.

The patient, aged thirty-nine, married, was admitted into University College Hospital on Dec. 10th, 1883; and she gave the following account of her illness. About Sept. 1882, she noticed a yellow discharge from the vagina, and since that time she had been getting thinner. She attended as an out-patient in June, 1883, and was prescribed a vaginal injection containing Condy's fluid. About a fortnight later, when administering to herself an injection, she noticed blood in the discharge. The blood appeared again when an injection was administered, and varied in quantity from time to time, and afterwards appeared independently of the injections. For nine months there had been pain during, and hæmorrhage after, sexual congress. For five weeks before admission the blood had increased in quantity and the discharge had been offensive. The patient began to menstruate at eleven years of age, and had always been regular until nine months before admission, the quantity lost being moderate. She had been married eighteen years, had had one child seventeen years ago, and one miscarriage a year later. She said that she had had inflammation of the womb three times, and had suffered slight scalding with micturition since she had rheumatic fever nine years before.

On admission she was thin, but looked fairly healthy, and weighed 6 st. 1 lb. External examination of the abdomen revealed nothing abnormal. On vaginal examination there was found what was taken for a red ulcerated surface, raised about one line above the level of the surrounding parts, and situated on the posterior lip and part of the anterior. There was a narrow strip of healthy mucous membrane on the posterior lip, between the growth and the insertion of the vagina, and another about three-quarters of an inch in width on the anterior lip. The red surface had the diameter of a florin. Four days before it was not bigger than a shilling, and affected chiefly the posterior lip. On the left side there was a fissure in the cervix, and the lips were everted.

The cervix was amputated above the internal orifice. The part removed was an inch and a half in length. On the posterior lip was no ulcer, but a raised papillary growth, about three-quarters of an inch in diameter, and on section its thickness was seen to vary from one-third to one-sixth of an inch. It was rough on its surface; and on its sides towards the commissure, and on the anterior lip, was a shallow, narrow, depression. At the border of this depression the stratified epithelium terminated abruptly; the border of the epithelium was sinuous and somewhat swollen, as if thickened. Posteriorly the stratified epithelium was retained up to the growth. The lips were everted, so that the disease appeared to affect the lowest parts of the lip; this was, however, not really the case, for it originated at the os externum, and was advancing along the posterior lip. On examining this specimen with the microscope, and beginning on the healthy surface of the portio, this was found covered by stratified epithelium; beneath the epithelium were the papillæ, somewhat enlarged: beneath these, again, was what appeared to be the healthy tissue of the cervix. As we approached the diseased part, the deeper layer of the stratified epithelium was found increased in thickness; small cells and nuclei appeared in great numbers in the tissue immediately beneath the thickened epithelium. Close to the new growth the stratified epithelium became greatly increased in thickness; here the papillæ became longer, and strings of epithelial cells ran into the tissues beneath, and papillæ grew upwards from the tissue beneath towards the surface, and penetrated the superficial thickened layer of squamous epithelium, as the processes from that epithelium penetrated the tissue of the cervix. These papillæ grew very rapidly, and over their points the horny layer of the squamous epithelium was, in the main, lost. It should be borne in mind that the deepest layer of the stratified epithelium of the cervix is formed of columnar cells, the cells of the middle layers are variously shaped, and the superficial cells only are flat. At the point where the deeper layers began to proliferate the superficial layer of flat horny scales was lost. As the growth proceeded the columnar cells forming the deepest layer lost their character, and abutting against the proliferating stratified epithelium was a thickness of what appeared to be indifferent tissue; beyond this was a string of cancerous cells, then again what appeared to be indifferent tissue. This might lead us to the conclusion that the cancer was really developed from connective tissue, both the connective tissue and the epithelial having been first transformed into indifferent tissue. The loss of the flat horny layer of the epithelium, and the apparent termination of the proliferating epithelium in indifferent tissue, appears to favour this view—a view which has been adopted by Ruge and Veit. A little closer examination, however, will, I think, show that the layer of indifferent tissue in which the proliferating epithelium seemed to end was a rapidly growing papilla—that this was making its way through the thickened epithelium to the surface, and that in the course of this process the horny epithelium fell off. The surface epithelium falls off as the result of the growth of tissues from beneath towards the surface, as I shall have occasion again to point out. The cords and strings of cancerous tissue which appeared in the growth, and which anastomosed freely, were not cancerous tissue developed from connective or indifferent tissue, but the thickened cancerous epithelium of the part penetrated through and through and in all directions by papillæ growing towards the surface, and the loss of the epithelium in places on the surface was the direct effect of the growth of the papillæ. The accuracy of this view of what occurs is shown by the fact that in other places the epithelium was continuous from the healthy

Digitized by Google

surface to the diseased, and that in many places in the diseased surface points were found denuded of epithelium. It is a curious fact that when papillæ grow on a uterine surface covered by columnar epithelium they are always covered by columnar epithelium; whereas when they grow on a surface covered with stratified epithelium the surface epithelium is lost—the horny layers are not compatible with growth.

CASE 3. — The third patient, a widow, aged forty-two, was admitted into University College Hospital on Nov. 26th, 1883. She had been treated on and off for perimetritis for several years. She said that twelve months ago the pain in the side for which she had been treated returned with great severity; it radiated from the left side of the lower abdomen. At the same time she had a dragging pain in the left axilla. Four months ago she noticed a greenish discharge from the vagina, which became offensive two months ago. The discharge was in considerable quantity during the day, and contained blood. During the last week the blood had diminished, while the discharge had increased, but the latter had to a great extent lost its fetor. The catamenia appeared first at eighteen; they had returned regularly since, in moderate quantity and without pain. The patient was married at twenty-two years, and had had seven children. The third labour was hard, but delivery was accomplished without the use of instruments. It was followed by a flooding. After this she said that she had inflammation of the womb and bowels. In her fourth confinement she was delivered of twins. She had had no miscarriages. The father died of asthma; the mother of a cause unknown to the patient; one sister died of cancer of the womb. The patient was fairly nourished; the heart and lungs were healthy. The cervix of the uterus was flattened and circular, almost like the head of a mushroom. There was a deep laceration in the left commissure, but the anterior and posterior lips and the right commissure were not torn. The cervix was amputated just above the internal orifice. The portion removed was an inch and a half in length. The posterior lip was the seat of a papillary growth one inch in diameter. There was a narrow strip of healthy mucous membrane between the disease and vaginal vault posteriorly. The vaginal canal appeared healthy. On microscopic examination, it was found that in places the superficial layers of the stratified epithelium were lost, and the deeper layers were exposed; in other places the superficial layers were retained, and the deeper layers were thickened and presented a wavy border. The disease was quite superficial, its thickness being not more than one-sixth to one-third of an inch.

(To be concluded.)

THE TREATMENT OF TYPHOID FEVER BY THE COLD WET PACK AND ALCOHOL.

BY JOHN CURNOW, M.D. LOND., F.R.C.P.,

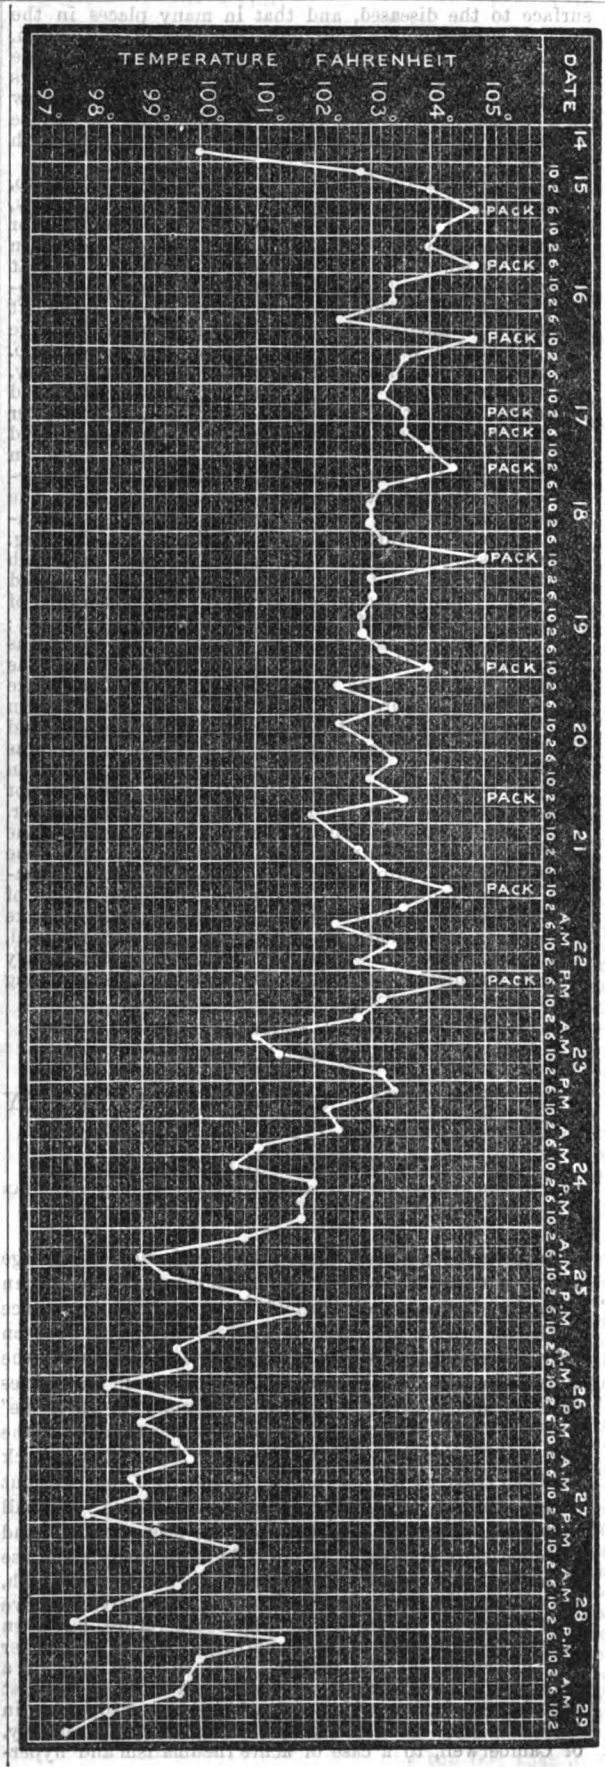
DEAN OF THE MEDICAL FACULTY IN KING'S COLLEGE, LONDON; PHYSICIAN TO KING'S COLLEGE AND THE SEAMEN'S HOSPITALS, ETC.

DURING the past few years I have had under my charge at the two hospitals with which I am connected more than three hundred cases of typhoid fever, and my experience has led me to a line of treatment in severe cases which has been very successful, but which is not quite in accord with the statements laid down by some of our most recent authorities on this disease. In "Quain's Dictionary of Medicine" Dr. Broadbent urges most forcibly the advantages of the cold-bath treatment, and states that "the cold wet pack has been tried as an alternative to the bath, but without effects adequate to the requirements of the case." I shall show that, when the cold wet pack has been carefully and systematically applied, it is not only more easily made use of, and is less distressing to the patient than the cold bath, but that it is an adequate and effectual alternative. I have used it not only in cases with high temperature, but even in cases complicated with hæmorrhage, and in the latter any movement of the patient, so as to place him in a bath, would have been attended with grave risk. My first experience of the cold wet pack as a remedy was in 1876. I was called in consultation with Dr. Massey, of Camberwell, to a case of acute rheumatism and hyperpyrexia. At 2.45 P.M. the temperature was 106·8° F., and was rising so rapidly that at 3.5 P.M. it was 107·2°. The patient, a young man about twenty-five years of age, was quite unconscious, and his pulse was so rapid that it could not be counted. It was impossible, for want of the necessary assistance in an emergency in a private house, to put him into a cold bath, so he was stripped naked, a mackintosh sheet placed under him, and he was wrapped in a linen sheet wrung out of cold water, kept at 32° by the addition of lumps of ice. The first application stopped the rapid rise in temperature, but the sheet began to get warm in two or three minutes, when another was substituted for it. On this being replaced by a third the temperature began to fall, and on further reapplications this fall became very decided and the patient's condition rapidly improved; his pulse fell, and he was soon quite conscious. After a continuous packing in this manner for four hours, and intermittent reapplications during the night, the tendency to an excessive rise in temperature gave way, and the patient recovered without any further complication or relapse. He had no cardiac mischief, and I saw him in perfect health only two weeks ago.

In typhoid fever the rise in temperature is more gradual, and the risk of a rapid death from hyperpyrexia is not nearly so imminent as in rheumatic fever. I therefore pack only the chest and abdomen, leaving the head and the extremities free, and a thin linen sheet is wrung out of ice-cold water and folded double, and used as in the case just recorded. This method of treatment is adopted whenever the temperature remains above 103·5° for any time (say twelve hours), and is continued until it falls to 102° or less. The pack is changed before it gets in the least dry, and another, wrung out as before, replaces it. When the temperature falls to 102° or less the patient is wiped dry, and the packing is stopped until the temperature again rises to 103·5°. In very severe cases the temperature is taken every half-hour or every hour. In a very protracted and severe case (J. A——), to which I shall presently refer, the patient was in the pack continuously for eight days and at intervals for five days longer, so that this treatment can evidently be carried out with benefit for a much longer time than is usually supposed.

In many cases, when the cold wet pack has been used to diminish the temperature, and to prevent it from rising above 104°, I have given no stimulants or drugs, excepting two or three grains of quinine two or three times daily. The patient is kept in bed, on a milk and beef-tea diet, and in an uncomplicated and ordinary case nothing else is required. I mention this particularly, because I do not prescribe alcohol in every case of typhoid. I have treated nearly 100 cases without any alcohol, and considerably more than this number with less than twenty ounces of brandy throughout the whole course of the illness and convalescence. I am quite convinced, however, that in exceptionally severe cases a much larger quantity of alcohol may be administered than is usually the practice, and in some desperate and apparently hopeless cases it is the only remedy that will save the life of the patient. It must be given with discrimination, and if its administration be carefully watched, and if the patient is improving or not becoming worse, there can be no valid reason why we should not push brandy as we do quinine, iodide of potassium, or opium in suitable cases. I quite agree with the late Dr. Murchison, that "fever may be treated successfully with little or no alcohol," and that it is "very rarely necessary to give more than eight ounces of brandy at any period of the fever"; but I must take exception to another of his statements, that "if, notwithstanding this amount (12 oz.), the patient die, it is doubtful if any amount of brandy would have saved him, and a larger amount would probably only have contributed to the fatal event." The cases which I record will prove that much larger amounts have not contributed to a fatal result, and I further believe that in these exceptionally severe cases the patients owe their lives to the large quantities of alcohol which were administered to them, and that they would not have recovered if any limit such as 12 oz. had been enforced, and I know that this opinion is shared by those who watched and nursed them.

The first case of typhoid fever in which I saw very large quantities of stimulants administered was during my house-physiciancy at King's College Hospital, when a domestic servant about twenty-two years of age was given one pint of brandy and some champagne daily for three or four



Digitized by Google

successive days. She recovered from one of the most severe attacks which I have ever witnessed. I saw her some years after, and she told me, in reply to my inquiry, that she had never tasted spirits after leaving the hospital, and that even taking them up to her master's study at night nearly made her sick, so much did she dislike their sight and smell. In another case, in which a nurse at the Seamen's Hospital in somewhat delicate health fell ill with typhoid fever, I was summoned by an urgent message and found her almost moribund, with a double hypostatic pneumonia, reaching on both sides as high as the spine of the scapula. Brandy in milk or beef-tea was given to her every twenty minutes for two days, and at gradually increasing intervals for some days after, with occasionally some champagne, and she made a good recovery. She is now the sister matron of a large provincial hospital, and has been actively and constantly engaged in nursing since her illness some eight or nine years ago. With the exception of taking a glass of beer with her luncheon, she has taken no stimulants since then. These cases show that brandy given in such large doses, instead of inducing people, especially women, to become drunkards, really have an opposite effect.

The method of administration which I follow in my worst cases is this: About three or four tablespoonfuls of milk or strong beef-tea are given regularly every twenty minutes or half-hour, and to these brandy is always added, the quantity being calculated so that the full amount of twelve, sixteen, twenty ounces, or even more, in the twenty-four hours, is equally distributed. If the patient refuses milk and beef-tea, as is occasionally the case, or the pulse becomes smaller and intermittent, a tablespoonful or a little more of champagne is used in their stead, and the brandy added to it, or if sickness be an urgent symptom the champagne is given freely for a few hours without brandy. In no instance has the brandy been given alone. The following cases are appended as typical of the advantages that have been derived from this plan of treatment.

CASE 1.—J. R—— was admitted on October 14th, 1884, having been ill with diarrhœa, occasional epistaxis and headache for nearly a fortnight. He had taken several doses of castor oil. On admission, there were tenderness and gurgling over the right iliac fossa, a few typical spots, and diarrhœa. His pulse was 96°, regular, and the temperature 102·4°. The diarrhœa continued. Next morning a smart attack of epistaxis occurred, and in the evening his temperature rose to 104·8°. He was constantly packed for twenty-four hours until the temperature was reduced to 102·4°, and, on its rising to or above 103·8°, this was repeated for the next seven days, after which he gradually improved. He had several attacks of epistaxis during this period, and his condition can be best appreciated from the notes for Oct. 23rd and 24th:—Oct. 23rd: The patient is very restless; tongue dark brown, covered with sordes; skin dry; bowels open three times; respiration 36; pulse 120, very small. 24th: Tongue black; muttering delirium throughout the night; quite unconscious; passes everything involuntarily; bowels open three times; he still takes milk well, although swallowing seems laboured. Respiration 40; pulse 128, so small as to be hardly counted. On the 27th his pulse was slower, temperature lower, and his tongue began to clean, and from this date his recovery was uninterrupted. The amount of stimulants which was given to him was as follows:—18th, brandy, 4 oz.; 19th, 4 oz.; 20th, 6 oz.; 21st, 10 oz.; 22nd, 12 oz.; 23rd, 14 oz.; 24th, 14 oz., and a pint bottle of champagne; 25th, 14 oz., and 2 pints of champagne; 26th, 14 oz., and 2 pints of champagne; 27th, 10 oz.; 28th, 6 oz.; 29th, 6 oz.; 30th, 4 oz.; 31st, 4 oz.; Nov. 1st, 2 oz.; making a total of 5 pint bottles of champagne, and 124 oz. of brandy. The temperature chart will show the severity of the case (by no means one of the worst), and the advantages of the cold wet pack and alcohol, which were freely used in the earlier stages of his illness.

CASE 2.—T. H—— was admitted on Oct. 3rd, 1884, after an illness of about fourteen days, but the patient was so prostrate that no reliable history could be obtained. He had some abdominal tenderness; his face was cyanosed; there was marked subsultus, a dry brown tongue, and a weak fluttering pulse of about 120. The temperature, which was 101·4° on admission, quickly rose to 104·2°. The area of splenic dulness was increased, and there were a few rose-spots. His condition from Oct. 9th to 15th is thus described in the case-book: "Patient lies quite unconscious; face blue; subsultus very marked; diarrhœa continues, and

Digitized by Google

occasionally a little blood in the motions, which, as well as the urine, are passed involuntarily; tongue black and dry; pulse 144, almost imperceptible." On the 15th he began to show some signs of improvement, and from this date he slowly progressed towards recovery, although there was a relapse lasting eighteen days. He was packed whenever the temperature rose above 103·5°; and the daily quantity of stimulants given to him was: on Oct. 3rd, 4th, and 5th, 10 oz.; 6th and 7th, 15 oz.; 8th, 15 oz. and 2 pints of champagne; 9th to 14th, 20 oz. and 2 pints of champagne; 15th, 15 oz.; 16th, 10 oz.; 17th to 22nd, 6 oz.; 23rd to Nov. 5th, 4 oz.; and Nov. 6th to 8th, inclusive, 2 oz.: making a total of 310 oz. of brandy and 14 pints of champagne.

CASE 3.—J. S——, aged nineteen, was admitted on Sept. 15th, 1884, after a week's illness. On admission his temperature was 103·6°; his pulse 120; tongue brown and dry; abdomen tumid; pain and tenderness on pressure over right iliac fossa; bowels loose; and there were a few rose spots scattered over his chest and abdomen. He became rapidly worse, with low muttering delirium; and on the 19th, at 9 A.M., his temperature having risen to 104·4°, he was packed, and this was renewed again and again, when his temperature rose above 103·6°. From Sept. 17th until the 27th inclusive he was quite unconscious: his pulse was 140 on the average, fluttering and irregular; he had some diarrhœa; and on the night of the 22nd his temperature fell 8° (from 105° to 97°), without any hæmorrhage, and everyone expected his immediate death. By the persistent application of warmth and the use of stimulants he rallied, and his temperature at 9 P.M. on the 23rd had risen to 103·8°. On the 27th he began to improve, and progressed favourably until Oct. 12th, having been allowed some custard on the preceding day. A relapse took place and continued until the 26th, and he then again went on satisfactorily until Nov. 12th, a slice of mutton having been given to him for dinner on the 9th, 10th, and 11th. A second relapse now occurred, but it lasted only three days. From this date he slowly convalesced, and was sent home to Norway on Dec. 12th. He was put on 4 oz. of brandy on Sept. 15th, 16th, and 17th; on the 18th, 6 oz.; on the 19th, 6 oz. and 2 pints of champagne; on the 20th and 21st, 10 oz. and the same quantity of champagne; on the 22nd and 23rd, 12 oz.; from the 24th to the 30th inclusive, 16 oz. daily; from Oct. 1st to the 4th, 12 oz.; from 5th to 8th, 8 oz. and 2 pints of champagne; from 9th to 17th, 4 oz. and 1 pint of champagne; on the 18th the brandy was raised to 6 oz., and again reduced to 4 oz. on the 25th, when the champagne was stopped; on Nov. 6th, 2 oz. only of brandy were given daily, and on the 9th its use was discontinued. The total quantity consumed by this patient was 388 oz. of brandy—2 gallons, 3 pints, 8 oz.—and 21 pint bottles of champagne.

CASE 4.—In the case of J. A——, who was admitted on Feb. 16th, 1884, we had to deal with the most protracted case which has come under my notice. He had been ill some nine or ten days previous to his admission, and the case ran a severe course for five weeks, after which he had a very severe relapse for about twenty days. During the first stage of the illness he was occasionally packed, and from 4 oz. to 8 oz. of brandy were administered daily. In the relapse he was packed almost constantly for eight days, and intermittingly for five days following, as his temperature when not in the pack was almost always 104°, and on two occasions reached 105°. Ten ounces of brandy and two pints of champagne were given daily throughout this relapse. His temperature for a fortnight was almost steadily above normal at some time of the day, and again rose after this, so that it was only on the 130th day, or after eighteen weeks of illness, that it became normal and steady. An exacerbation on the 128th day was probably malarial, as it gave way to 20 grs. of quinine administered in a single dose. He took brandy daily from his admission to April 14th, and 6 oz. of Tarragona port from that date until June 21st, when he was able for the first time to sit up in bed. His temperature fell suddenly on one night during the first relapse from 105° to 96·2°, and the fall coincided with severe vomiting, but there was no hæmorrhage, sweating, or profuse diarrhœa. For the last nine weeks of his illness, during his third pyrexial rise, he took 5 grs. of quinine every four hours. Fresh spots came out during both his relapses. He was kept on milk, with occasionally beef-tea, from Feb. 15th to April 19th, when some custard was allowed. On the 24th a little bread was given, but this and the custard were stopped on the 26th; they were resumed on May 10th. Fish was added on the 21st. A mutton chop replaced the fish on June 2nd, and on the 26th he was put on the ordinary hospital regimen.

I have selected these cases as typical examples of the advantages derived from wet-packing and free stimulation, as they were for longer or shorter periods in the most imminent peril, and in all of them complete recovery took place, notwithstanding, as some would say—or in consequence of, as I should say,—the amount of alcohol which was administered. All credit must be given to my house-physicians—Dr. E. Penny and Dr. E. H. Booth—for their assiduous attention, and to the excellent nurses who watched over these sailors. It must be remembered that the cases of fever admitted into the Seamen's Hospital are on an average more severe than those seen in general hospitals, for the patients have usually been kept at work as long as they could move about the vessel; that they have had no rest, medical attendance, or proper dieting previous to their admission; and that they are all adults, in whom a high rate of mortality is to be expected. In the past seven years I find that only eight deaths have occurred in the cases under my care, of which four were due to hæmorrhage, two to perforation of the bowel and peritonitis, one to exhaustion and thrombosis of the veins during a relapse and one to pneumonia.

SURGICAL MISHAPS.

BY T. PRIDGIN TEALE, M.A., F.R.C.S.

SURGICAL mishaps are happily not always identical with surgical calamities, as the following three cases, slightly sketched without much detail, will show. The narration may be useful, and may bring comfort to others who meet with similar occurrences.

CASE 1. *Disappearance of Tumour after ineffectual attempts at Removal.*—I cannot do better than describe this case in the words of a letter which I wrote to Sir James Paget on Jan. 11th, 1878: "Mr. H——, of H——, consulted me three weeks ago about a tumour behind the angle of the left lower jaw. After existing for several years as a small movable lump, the tumour had within a few weeks begun to grow with an increasing rapidity. It was fairly movable in all directions, and I advised its removal. A fortnight later I went over to H—— to remove it, and then found that the tumour had become at least double in size, was very elastic, and more fixed. I cut down upon the tumour, and found that it involved, and seemed to be growing in, the anterior portion of the sterno-mastoid, and that it had no limiting capsule, as I hoped. Having stripped the outer side of the tumour with the finger, separating it from contiguous fibres of the muscle, I followed it deeply until I could almost touch the transverse processes, where it was firmly attached to deep structures in the neighbourhood of the large vessels. I therefore thought it more prudent to abandon any further attempts at removal. Having inserted a drainage-tube, I closed the wound, and all healed satisfactorily. Curiously, the rapid growth seems to have been checked, and this makes me regret that I did not strip the opposite side also, with a view to cutting off supplies." Sir James Paget and Mr. John Wood, who saw the patient, after hearing my description of the operation, agreed that no further surgical interference was advisable, and the former suggested a course of small doses of iodide of potassium, with large doses of liq. potassæ. On April 24th Mr. H—— wrote that, apparently under the influence of the medicine, the tumour had decreased so rapidly that ten days previously he had omitted the medicine, and that "it is now scarcely feelable and not perceptible." In December, 1878, he again wrote, "The tumour, or whatever it was, has departed in peace, seemingly never to return." I have heard of him from time to time, but never of any relapse.

Dec. 25th, 1886.—Mr. H——writes: "The tumour had existed two years before the operation. There is not a trace at present. I took about six bottles of the medicine, and the tumour disappeared in six months."

CASE 2. *Chronic Inversion of the Uterus; Attempted Reduction by Taxis: Laceration of Vagina into Douglas's Pouch; Recovery.*—Mrs. J——, aged twenty, was sent to me in November, 1884, by Dr. Blair, of Goole, suffering from inversion of the uterus resulting from her second confinement four months before. The labour was prolonged and difficult. She remained in bed for a week after delivery,

Digitized by Google

and on getting up for the first time the womb came down and protruded nearly two inches. The womb was returned, and never prolapsed again, but it was afterwards discovered that she was suffering from inversion of the uterus. The patient was anæmic and frail-looking. In consultation with my colleagues, it was considered that the os and cervix were so much relaxed that I might attempt to reduce the inversion by taxis whilst the patient was under ether. I therefore at once made the attempt, using, as I believed, no immoderate force, and fully realising the need of caution so as to avoid the danger of laceration. After careful pressure with the fingers upon the fundus, which in about a quarter of an hour had been reduced to within the level of the os, and just as it seemed that complete reduction was being effected, the whole receded within the peritoneal cavity through a rent in the roof of the vagina, posterior to the cervix. I was then face to face with a most difficult problem, and called to my aid Mr. Robson, who was in the Infirmary at the time. After some deliberation, we came to the conclusion that the safest course would be to transfix, tie, and cut off the inverted womb. This having been done, one stitch was inserted into the rent in the vaginal wall as a safeguard against prolapse of the bowels, and a large drainage-tube was inserted within the lips of the wound so as to project for about an inch into the peritoneal cavity, and was fixed by catgut sutures to each side of the ostium vaginæ. The vagina was carefully syringed with weak carbolic acid lotion, and well charged with iodoform. Her further progress was satisfactory. There were never any symptoms of peritonitis. In a few days her temperature rose to about 103°, and then slowly fell, and she returned home within three weeks of the operation. I have since heard that she is in good health, and menstruates regularly.

Dec. 25th, 1886.—Dr. Blair writes me: "Mrs. G—— is quite well; menstruates regularly, and suffers neither pain nor inconvenience."

CASE 3. *Wound of Popliteal Artery and Vein during an Operation for Necrosis of Femur; Recovery without Gangrene.* A young man, aged about twenty-one, came under my care at the Leeds Infirmary about six years ago, on account of necrosis of the femur. The sinuses led to the back part of the femur, about the bifurcation of the linea aspera. Having enlarged the sinuses, I had considerable difficulty in reaching the denuded bone. In trying to release what seemed to be an indurated edge of fascia or a ridge of new bone, I passed the knife along this edge, loosening it, as I thought, from its apparent attachment to the bone, when a gush of hæmorrhage startled me. To my dismay, the cord proved to be the popliteal vessels coated with a tough hard case of cicatricial lymph, and both artery and vein were wounded. Having commanded the breach in the vessels by the finger, I sent for my colleague Mr. Wheelhouse, who fortunately was paying his visit to the wards, and most kindly came to my assistance and gave me timely aid and counsel. Finding it impossible to deal effectively with the wounded vessels through the lateral wounds, I made a vertical incision about four inches long in the middle of the popliteal space, and so exposed the wounded vessels. Having severed the vessels at the seat of injury, I tied both ends of the artery and vein. The whole proceeding was both difficult and tedious. For some days I watched the case with grave anxiety, fearing gangrene and the need of amputation. Fortunately my fears were disappointed. The foot soon became warm, was never blue, and gave me no cause for anxiety. The wound healed favourably, and the patient recovered the use of the limb. Knowing the frequency with which gangrene results from arrest of circulation through both the main artery and vein of a limb, the impunity which resulted in this case was unexpected, and gave great relief to my mind.

Leeds.

PRESENTATIONS.—On the 21st ult., at Camberwell, Mr. Oldfield was presented with a marble timepiece and a purse containing £150, as a token of the esteem in which he is held, and as a mark of sympathy with him in the trouble entailed by an action which was brought against him, and summarily disposed of by the Grand Jury at the Central Criminal Court.—Mr. H. E. Richardson, who has recently resigned the post of senior house-surgeon to the Birkenhead Borough Hospital, has been presented by the nurses and others connected with that institution with a surgical case and other gifts, as a token of the high esteem felt for him.

CLINICAL AND PATHOLOGICAL ILLUSTRATIONS OF CEREBRAL LESIONS.

BY DAVID DRUMMOND, M.D.,
PHYSICIAN AND PATHOLOGIST TO THE NEWCASTLE-ON-TYNE INFIRMARY.

CASE 1. *Double Cerebral Lesion simulating an Apopletic Bulbar Lesion.*—A boiler-smith, aged sixty-five, complained of nothing of importance until he reached the age of sixty, when he experienced "a very slight stroke," which affected his left side somewhat. Eighteen months later another somewhat similar seizure overtook him, also affecting the left side. His articulation now became difficult, and it was observed by his friends that his face was smooth and expressionless. Soon after this attack he came for the first time under observation, when the following points were noticed. The patient could walk, but he dragged the left leg slightly, whilst his grasping power was decidedly weaker on the left side. The face presented a stupid, stolid expression, the result of incomplete double facial paralysis. The tongue was protruded straight, but with undoubted difficulty, for the tip scarcely reached beyond the lips. The saliva constantly dribbled from his mouth. The speech was exceedingly indistinct, but there was an absence of true aphasia. One could imitate his attempts at articulation very readily by speaking with the mouth open and the tongue still. Both vocal cords were seen with the laryngoscope to be considerably relaxed. His attempts at swallowing were attended with great difficulty, and fluids frequently regurgitated through the nasal passages. I observed this patient for a considerable time before more alarming symptoms set in, and by degrees the signs suggestive of a bulbar lesion became intensified. The double facial and hypoglossal paralysis, the imperfect articulation, the difficulty in swallowing, all advanced together, whilst as time went on there was comparatively little alteration in his locomotion and grasping power. At length one day he was brought into the infirmary, having just had, it was stated, another seizure. It was then observed that, although conscious, he was almost speechless; the tongue could not be protruded; the lower facial muscles were completely paralysed; swallowing was almost impossible; both legs and the left arm were markedly paralysed, and the right arm enfeebled. After lingering in this condition for about three weeks, he sank and died comatose.

It was obvious that we had in this case to do with many of the features of an acute labio-glosso-laryngeal paralysis, such as Leyden and others have described as resulting from hæmorrhage or softening in the medulla. At the necropsy, however, the medulla and pons were found to be normal. The dura mater was thickened and firmly adherent along the edges of the longitudinal fissure; the pia mater and arachnoid were also thickened and presented the sodden wash-leather appearance so suggestive of general paralysis of the insane. The brain substance was of soft consistency. The vessels at the base were atheromatous, and in places markedly thickened, especially the termination of the internal carotid, the middle cerebral, and the posterior communicating on the left side. On cutting the cerebral hemispheres in the usual way, two patches of degenerated brain tissue were observed as the lower levels of the centrum ovale majus were reached, one in each hemisphere; these resembled cicatricial tissue. That on the left side appeared to be placed just above the posterior and middle portion of the optic thalamus, and that on the right was situated a little in front and to the outside of this point. The next section brought into view two cicatricial and cyst-like areas of degeneration. In the left hemisphere the disease occupied the anterior and inferior portion of the optic thalamus and the adjacent centre of the internal capsule, almost at its lower part; whilst in the right hemisphere it was found to implicate the lenticular nucleus of the corpus striatum (especially its middle and posterior portions), the middle of the internal capsule with the posterior part of its anterior division, and the external capsule. Thus it will be seen that the symptoms were due to two lesions which were almost symmetrically situated in each hemisphere. The diagnosis from bulbar disease was by no means easy, and practically rested alone upon the history of distinct hemiplegic seizures; but it must be borne in mind that there was no account obtained of a right-sided

Digitized by Google

hemiplegia, and I am inclined to think that the lesion in the left hemisphere was not followed by hemiplegia proper, but simply by paralysis of facial and hypoglossal nerves, the arm and leg paralysis developing later. This opinion is justified by the fact that the lesion was an old-standing hæmorrhage, whilst the paralysis of the right arm and leg only took place a few weeks before the case terminated, being due, in all probability, to an extension of the softening in the neighbourhood of the primary lesion.

CASE 3. *Disseminated Cerebro-spinal Sclerosis; Glycosuria.* Ed. H——, a boy, aged eight years, first came under observation in July, 1885, for headache and a staggering gait. It was stated that he had been ill for three months. There was neither vomiting nor optic neuritis. The speech was slow and hesitating. There was very slight tremor of the arms, but no pronounced paralysis of either upper or lower extremities, and the legs were free from rigidity. There was no nystagmus. The urine was normal; in some weeks, however, it increased in quantity, and sugar appeared. About this time he became gradually blind, and the discs grew white. The auditory nerves also became affected, causing deafness. The legs grew very feeble, but never remained flaccid, though the knee-jerk was increased. Three weeks before his death, which occurred thirteen months after the onset of the cerebral symptoms, the patient was confined to bed with paralysis of both arms and legs, though the former were affected to a slighter degree. His mental state towards the end grew very feeble, but diabetic coma never made its appearance. At the post-mortem which was incomplete, as it had to be made in the patient's home under rather trying circumstances, the body was seen to be markedly emaciated. The brain weighed 46 oz. The basal arteries were normal, but the small vessels of the pia were deeply congested. The convolutions were flattened, and to the touch the posterior parts of the hemispheres were harder than the anterior. Sections exposing the upper part of the basal ganglia revealed in the white matter symmetrically arranged patches of sclerosis, which passed backwards from opposite the middle of the optic thalami on each side. These sclerosed areas were very extensive, and were found to invade the occipital lobes to a marked degree. The grey matter was normal. Nodules were found in the upper part of the spinal cord, and one was observed in the white matter of the left hemisphere of the cerebellum, whilst another occupied the medulla, appearing on the surface of the floor of the fourth ventricle about its centre. The spinal canal was not opened.

CASE 4. *Injury to the Head; Chronic Meningitis; Ventricular Effusion; Minute Hæmorrhage in the Upper Part of Floor of Fourth Ventricle; Diabetes.*—A boy aged seven was admitted into the infirmary in a very emaciated condition, complaining of great thirst and other symptoms of diabetes. It was stated that he had received a blow on the head some four or five months previously, and that he had suffered ever since from headache. The urine was full of sugar. He died in a state of diabetic coma two days after his admission. At the necropsy the body was found greatly wasted and post-mortem rigidity very pronounced. The stomach was considerably dilated, and its walls were very thin. The liver was pale, but a large quantity of blood poured out from the cut veins. Brain: The dura mater was strongly adherent to the upper part of the occipital bone. There was a slight amount of subarachnoid effusion. The pia mater beneath the cerebellum was much thickened and congested, especially the portion, forming the roof of the fourth ventricle. The lateral ventricles were dilated and contained fluid. The iter e tertio ad quartum ventriculum was considerably dilated, and the usually smooth surface of the floor of the fourth ventricle presented a large number of minute glistening elevations, the whole resembling the ground-glass appearance of the ependyma so characteristic of general paralysis. A small hæmorrhage occupied the central fifths 4 mm. above the linea transversa and 16 mm. above the calamus scriptorius.

CASE 4. *Tumour of the Left Cerebellar Lobe; Convulsions, with Rotatory Movements from Left to Right; Ventricular Effusion; Glycosuria.*—Henry M——, aged seven years, was admitted into the infirmary complaining of pain in his head of two years' duration. Twelve months after the commencement of the symptoms vomiting and staggering gait made their appearance, and the attacks of headache became much more severe. On admission he was particularly had severe occipital pain, which culminated in convulsions, at the height of which he generally vomited. The knee-jerk was absent. The optic discs were markedly atrophied. There was no nystagmus, nor was there any retraction of the head. The urine contained sugar, but not in large quantities; the specific gravity was never above 1025. The day before his death two fits occurred; he lost consciousness during the convulsions, and each time *rolled from left to right*. At the necropsy the body was found to be well nourished; rigor mortis marked. The head only was examined. The convolutions of the convex surface were flattened. The veins were full. The pia mater covering the pons was thickened. The optic nerves were greyish and firm. The lateral ventricles were considerably dilated, and contained fluid. The veins of the ependyma were distended. The left hemisphere of the cerebellum contained a firm tubercular growth the size of a walnut. This tumour extended slightly over the middle line to the right side, and to within half an inch of the lateral surface of the left. The effusion had evidently reached the fourth ventricle.

CASE 5. *Complete Hypoglossal Paralysis depending upon a Lesion in the Left Internal Capsule.*—A labourer, aged fifty, had what was described as a "stroke" three months before he came under observation. Consciousness was not lost in this attack, and the only result was paralysis of the right side of the face, with inability to protrude the tongue, and difficulty of articulation, so that his friends did not understand what he said. Seven weeks subsequently he had another attack, in which his face became more profoundly paralysed and his right arm and leg were affected. He was now, it was stated, deprived completely of his speech. On admission into the infirmary the right leg and arm were almost helpless and late rigidity was commencing. The right side of the face was also paralysed, and the power of protruding the tongue was lost. Even efforts such as are wont to arouse automatic tongue movements failed—such, for example, as holding a lozenge near his lips, and at the same time showing him what was required of him. For some weeks he lay in this condition; but by degrees the general nutrition failed, the tongue as it lay in the mouth became foul and covered with a thick dry crust, and he began to refuse food. In a short time he died, without the development of any further seizure. At the post-mortem examination a considerable quantity of fluid escaped when the dura mater was opened. The superficial veins of the hemispheres were much congested. The arachnoid was cloudy, and enclosed some serous effusion. The basal vessels were much degenerated—viz., the vertebrals, basilar, posterior cerebrals, and especially the middle cerebrals. The lenticulo-striate branch of the left middle cerebral was completely blocked and thrombosed. A patch of softening was found occupying the posterior part of the caudate nucleus and adjacent anterior portion of the optic thalamus, as well as the central division of the fibres forming the internal capsule. The right hemisphere appeared to be free from disease.

In this case the aphasia scarcely corresponded with Lichtheim's published views on the variety of aphasia that results from a lesion of the afferent fibres connecting the "speech centres" with the medulla,[1] inasmuch as the patient had not quite lost volitional speech or the power of repeating words. He could always, for example, when asked his name, mumble it in such a fashion that anyone familiar with its sound could recognise the attempt at articulation, and efforts were made to reply to other questions in the same imperfect manner. The case is important as showing that the impression that "a bilateral lesion is required to produce paralysis of the motor organs" (of speech)—to quote from a recent writer—is not always the case, for in this particular instance bilateral movements of the tongue would appear to have been excited by innervation from the left hemisphere alone.

(To be concluded.)

MANCHESTER ROYAL INFIRMARY.—An addition has just been made to the collection in this infirmary of portraits of distinguished members of the medical profession, by the presentation by Mr. Charles Jordan of memorial busts of two eminent surgeons, Charles White and Joseph Jordan, who did much during their lifetime to advance the importance and value of the charity to the city.

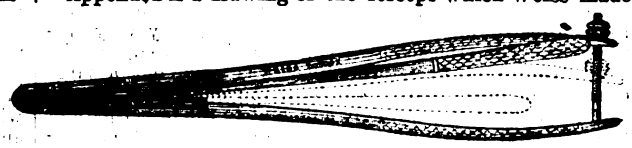
CASE OF

SUCCESSFUL REMOVAL, PER VAGINAM, OF A CANCEROUS (AND PREGNANT) UTERUS.

BY J. GREIG SMITH, M.A., F.R.S.E.,
SURGEON TO THE BRISTOL ROYAL INFIRMARY.

THE patient, a well-nourished woman, aged thirty-four, was admitted to the Bristol Royal Infirmary in September, 1886, with characteristic and well-marked signs of uterine cancer. She had had eight children (twins on two occasions), and her frequent and excessive hæmorrhages had been attributed to miscarriages. It is very probable that she had had miscarriages; indeed, it was suspected before operation that she was pregnant, though bleeding had been almost continuous up to the date of admission.

The epitheliomatous growth was for the most part confined to the cervical canal. Hard cauliflower granulations sprouted from the os, and the whole of the posterior lip was occupied by nodular growths, which bled freely on being touched. The vaginal portion of the cervix and the growth in it together were in bulk about as large as a tennis-ball. The contiguous vaginal surfaces were healthy; the uterus was freely movable, though it was considerably enlarged (the sound entered four inches); signs of implication of glands, broad ligaments, bladder, or rectum were absent; and the patient was in good condition, though anæmic. On the whole, it seemed to be a suitable case for operation. The decision was not definitely to remove the whole uterus, but to begin as if for supra-vaginal amputation, and, if this operation did not seem radical enough, to perform total hysterectomy. The first steps of partial amputation, as I perform it, are identical with the first steps of total amputation. When the cervical mucous membrane is detached the finger can reach as high as the internal os outside, and, being in actual contact with uterine fibres, can diagnose the condition with accuracy. Pregnancy would have little influence either way; probably its existence would favour complete removal. After partial amputation abortion would take place, and the bleeding and discharging would add to the patient's risk.



Preliminary cleansing of the parts was carried out for three days before the operation, and immediately before operating the whole of the genitals were washed with 1 in 20 carbolic lotion. The patient was placed in the lithotomy position. The cervix was caught in strong vulsellum forceps, which were entrusted to an assistant, who pulled down the uterus, and manipulated it according to direction. The mucous membrane surrounding the cervix was divided all round by scissors at a safe distance from the new growth, and was dissected upwards by scissors and fingers, catch forceps being placed on bleeding points. As high as dissection could be carried without entering the peritoneal cavity induration was felt in the uterine tissue; it was therefore decided to remove the whole organ. The peritoneum behind was perforated by the finger close to the uterus, and enlarged laterally by tearing. In front the peritoneum was opened by pushing a Lister's sinus forceps through it close to the uterus, and the opening enlarged sufficiently to admit the finger by separating the blades. The finger, inside the abdomen, readily tore the peritoneum from the uterus close down to the broad ligaments. I then endeavoured to hook the finger over the top of the broad ligaments so as to place on them the clamp forceps which I had some time previously devised for the purpose. But the ligaments were so much elevated by the enlargement of the uterus that I could not reach high enough; and, besides, they were so voluminous that the clamp could not have efficiently grasped them; I therefore proceeded to antevert the uterus. This was done by taking successive grips of its anterior surface by means of powerful catch forceps, placing one above the other, and so gradually and completely anteverting the whole organ. A sponge had been previously placed in the abdominal cavity through the posterior opening to keep the bowels out of the way and absorb any fluid that might be effused. The fundus now lay between the labia, distending the vagina. By dragging it to one side and retracting the labia the top of one of the broad ligaments could be brought within reach. A powerful Wells's forceps was made to grasp as much as possible of the ligament (including the Fallopian tube and round ligament of course) close to the uterus. A corresponding depth of the ligament was then caught in a silk ligature at a distance of about a third of an inch from the forceps and divided between. This division enabled the uterus to be drawn down a little further. Three other ligatures were successively placed in the same way, and one side of the uterus was thus fixed, the catch forceps being left on the uterus. The same proceeding was then carried out on the other side, and the uterus was removed. The vessels in the broad ligament were very large and very numerous, and it was deemed wise to leave the catch forceps attached to the ligaments where the vessels were most numerous, so as to give extra security against hæmorrhage. These were removed after twenty-four hours. The sponge was now removed from the abdominal cavity; a clean sponge reintroduced removed all blood clot, and at the same time pulled the peritoneal flaps downward over the mucous flaps, so that the rawed surfaces lay in contact and the serous surfaces were apposed. No stitches were used. The vagina was finally cleansed; iodoform powder was insufflated, and pure boroglyceride smeared all over the external parts. A small plug of iodoform wool in a fold of carbolic gauze was placed in the vagina to fix the forceps. The operation occupied about forty minutes.

Next day the vaginal plug was taken out and the forceps removed. In the track of the forceps an ordinary glass drainage-tube was carried inside the abdominal cavity, the end lying outside the vulva. By means of an irrigator the cavity was washed out through the tube with warm boroglyceride solution every six hours. Before each cleansing the urine was drawn off; then the genitals were washed, the tube isolated with sal. alembroth wool, and plugged with a roll of wool, which at once acted as a capillary exhauster and as an antiseptic. After four days the tube was removed, as there was no discharge; but vaginal irrigation was continued for a few days longer.

The patient's recovery was most easy and straightforward. On the second day there was some tympanites, which was relieved by a turpentine enema. On the third day a saline purge was given, followed by another enema, and thereafter tympanites gave no trouble. There was no sickness. Her progress was, in fact, as rapid and as satisfactory as that seen after an ordinary ovariotomy.

The uterus, on bisection, was found to contain two fœtuses and their membranes, about six weeks or two months old. But its measurements were larger in proportion, as might be expected. The cancerous growth in the cervix was much crushed by forceps, and the fundus and sides were also compressed and flattened by instruments, so that the measurements were inexact. Roughly its length was about seven inches, the other dimensions being proportionate. The disease extended up the whole of the cervical cavity, and abutted on the fœtal membranes.

Appended is a drawing of the forceps which Weiss made

for me some months ago for the purpose of clamping the broad ligaments. It consists of two grooved blades, which lock over the top of the broad ligaments, and are tightened by a screw at the end of handles which lie in the vagina and pass outside the vulva. On the inner aspect of the clamp grooves are placed to carry a small knife, with its edge set obliquely to the handle. When pushed up the grooves it cuts the broad ligament away from the uterus. The clamps, one on each side, are placed and tightened, and when the circulation is thus completely stopped the uterus is cut loose by simply pushing the knife up the grooves on the clamp, first on one side and then on the other. The compressing edges of the clamps are deeply slotted to prevent the possibility of their slipping; elsewhere they are rounded and smooth so as to avoid irritation of peritoneal surfaces. It matters little whether the anterior or the posterior blade is first placed; only the grooves must be placed towards the uterus.

It has been abundantly proved that crushing or compression maintained for forty-eight hours on vessels the size of the uterine arteries is efficient and trustworthy for per-

Digitized by Google

manent hæmostasis. The instrument is intended to avoid the chief difficulty in kolpo-hysterectomy—the application of ligatures to the broad ligaments. It also renders the operation an extremely easy one. On the dead body it is possible to remove the uterus in five minutes and leave the parts in a satisfactory surgical condition.

Remarks.—The latest statistics of kolpo-hysterectomy show, in a total of 350 cases, a general mortality of about 26 per cent. This mortality is steadily decreasing. In the hands of specially skilful operators the percentage of deaths is under 10; indeed, a hundred cases could be gathered as representing the whole of the operations of four men, with a death-rate of only six. Brennecke and Schede can show records of 18 and of 16 operations respectively, all successful; Fritsch has lost 2 out of 24; Martin is well through his second 50 operations, with a mortality under 9 per cent.; and Sänger, with a few others, have almost equally brilliant results.

The amount of literature which has accumulated around the operation is truly enormous. The variations in details are very numerous and very confusing; but unessential details are being eliminated, and the methods are now settling down to a few definite practices which are followed by the most noted operators. The essential details in the operations I would shortly describe as follows:—1. Thorough preliminary cleansing of the accessible genital parts. This ought to include the vulva and labia, as well as the vagina and cervix, and ought to be particularly exact in the deep sulci of the external parts, which are so liable to harbour filth. 2. A bladder and rectum perfectly empty and collapsed. A sound in the bladder is quite unnecessary. The forefinger, after a little practice on the cadaver, can readily feel and recognise the bladder wall, and easily diagnose its relations. 3. Circular denudation of the mucous membrane surrounding the cervix, and separating it, close to the uterus, as high as it will go without force. 4. Perforation with finger or blunt instrument of the peritoneum behind and in front of the uterus, and close to that organ. If a blunt instrument is used the bowels cannot be wounded, and if perforation is made close to the uterus, the rectum cannot be wounded behind nor the bladder or uterus in front. The peritoneum is to be separated from the uterus laterally as far as the broad ligaments, and no further. 5. Efficient surgical hæmostasis of the vessels in the broad ligament: This may be done by temporary forcipressure, or by compression instruments such as those I propose, the uterus being cut away between them. If deligation be decided upon, inversion of the uterus renders the method easier. Silk is a trustworthy ligature, and simpler of application than any other. 6. Apposition of serous and of raw surfaces. This may be effected by simply pulling out of the abdomen into the vagina a sponge placed there at an early stage of the operation; stitches are unnecessary, as the parts lie naturally in apposition. This arrangement of flaps permits of free drainage from the peritoneum, and from the denuded surfaces back into the vagina. 7. Abdominal drainage per vaginam for a few days is expedient, if not necessary. If clamp forceps are used drainage may be dispensed with. A simple straight tube is quite efficient.

Bristol.

NOTES OF A

CASE OF ACUTE DIFFUSED MYELITIS; RECOVERY.

By F. R. FAIRBANK, M.D., L.R.C.P. LOND.,
SURGEON TO THE DONCASTER GENERAL INFIRMARY.

DISEASES of the spinal cord are now attracting so much attention that the notes of the following remarkable case may be perused with interest. It is probably seldom that recovery—complete recovery—takes place in so severe an attack as that which is the subject of these notes. The absence of the complications in the chest and on the surface, which so commonly occur in cases of myelitis, was greatly due to the high character of the nursing which the patient was fortunate in receiving. She was unable to lie on her side on account of the pain which it occasioned. She was therefore kept with her shoulders raised as much as possible, and moved frequently. The nates were carefully protected with pads of cotton-wool, and the utmost cleanliness was observed. At one time the paralysis was so complete that she was unable to move any part of her body, and the respiration was of the shallowest possible character. Careful inquiry elicited an exposure to cold as the cause of the mischief. But there was no reason apparent why the spinal cord should specially suffer. Much care was taken with the use of galvanism, and its effect on the patient was carefully watched; I have seen much mischief occasioned by the too early use of it in cases of myelitis. The notes appended by Dr. Clifford Allbutt, who saw the case with me, and by Dr. Gowers, who has been kind enough to criticise the case from my notes, will be read with interest

Miss ——, aged sixty-five, was first seen on Oct. 25th, 1885. A short, spare woman, hair white, of a kind disposition, cheerful, and thoughtful for others. Has enjoyed good health; father suffered from gout. Called me in to see her for pain in the lower end of the œsophagus on swallowing, "as if something had stuck in her throat." There were symptoms of subacute gastritis. In the course of three days the gastric symptoms were relieved, but the pain on swallowing remained. Right sciatica now came on, followed next day by extension to the left side, and the day following she faltered in rising from her seat. I sounded a note of alarm, and requested a consultation with Dr. Clifford Allbutt. She rapidly became much worse. The legs became paralysed, the arms painful down the course of the main nerves, the breathing shallow, and there was a feeling as of a cord being round the waist and also round the legs. When her legs were lifted from the bed they "flopped about." There was great weakness of hands and arms. Bowels confined; urine escaped involuntarily. The pain in the limbs was much worse after movement. There was considerable cerebral excitement. My diagnosis was "spinal meningitis—myelitis." I gave her bichloride of mercury, iodide of potassium, and cinchona. This was her condition when on Nov. 3rd I saw her with Dr. Allbutt. We then examined her together. She was able to say which leg was touched, and felt the difference in succession when touched with sharp points. When seen it was afternoon, and she expressed herself and appeared slightly better than she had been in the morning. This suggested to Dr. Allbutt the idea that the case *might* be one of peripheral neuritis, and inquiry was made as to the patient's habits, with negative results. But for this he would have diagnosed acute ascending paralysis. The improvement was, however, most transient. She rapidly got worse and could not raise her head, and when it was raised it moved powerlessly about. The patient's breathing was shallow in the extreme, and hurried. The pains in the limbs subsided as the paralysis increased. The fæces had to be scooped out of the rectum by the nurse. The urine would only flow through the catheter when the body was firmly pressed by the hand. When either knee was touched she could tell the difference, but if one was touched after the other she was not aware of the change. When at the worst, she appeared unable to see the night through on account of the inability to breathe. She was then entirely powerless from head to foot. There was extreme emaciation. I gave her dilute phosphorus acid, ammon. carb., and cinchona, with a draught of hydrate of chloral with bromide of ammonium at night, as she could not sleep. Reflex contraction was lost at the knee and the sole of the foot. From the worst point she gradually improved. The breathing gradually became deeper, then she could swallow a little better, then move a finger. Her hands, as she improved, were held straight (unbalanced action of extensors), and were stiff and tremulous, and felt soft and puffy. She gradually got power of control over the bladder; first she could empty it herself when the catheter was introduced, then she could control the action of it. The urine had become muco-purulent; this improved. The legs could after a time be moved, "after the nurse had worked them about freely first." Power returned in the flexors of the legs before the extensors; the reverse in the hands. I changed the medicine to bromide of ammonium with oxide of zinc, with sleeping draughts of morphia and belladonna. There had been no indication of lung mischief apart from the paralysis. The temperature had not exceeded normal. There was no facial paralysis. This report is to Dec. 11th, 1885.

On Dec. 21st the report was as follows:—Can move her left hand above her head. Able to sit on the edge of the bed with assistance. Has not passed urine involuntarily for the last fortnight; it has been drawn off by catheter. More control over the rectum; fæces have not now to be scooped out. Can raise her thighs to a right angle. Has very

Digitized by Google

little power over the muscles of the leg, and the feet fall. When the front of, say, the left leg is rubbed, can tell which; if the right be then rubbed also with the other, does not detect any difference; then when the right is continued to be rubbed and the left is let alone, is not aware of the change. Has all along, with the improvement, suffered from painful sensations over her body, which she has spoken of as "fidgets"; these were almost continuous, but have now changed into paroxysms, more severe while they last, but with intervals of ease. Along with the bodily improvement her mind has become alienated, and her disposition entirely changed. She screams at the top of her voice frequently through the night and day, and when told how seriously this interferes with other people's comfort, says she does not care; it is nothing to her if they are kept awake all night by her noise. As she has become able to move her hands, &c., they have become subject to fits of uncontrollable movement after voluntary effort. There has throughout been no tendency to bedsores; very great care has been taken to guard against this.

March, 1886.—Has had a long, weary time of it. Can now walk about her room; at first with assistance, now without. Can feed herself, and write letters with great effort. Has still pain after movement, and general feeling of distress all over her body. Disposition again natural. Bowels usually moved without enema, with a pill every other night. Has severe pain after passing urine. Small quantities of pus come from the vagina (there had been symptoms of a small pelvic abscess which burst through the vagina). Legs are plump again; pain in the joints, knees especially, much less. There had been considerable redness about the right patella.

The patient subsequently went on improving. Great care was taken with the muscles to prevent degeneration—by movement, rubbings, galvanism, &c. The medicines during the later period of convalescence were nux vomica, arsenic, iron, and valerian. Went away to the seaside and elsewhere for change of air, and returned home by midsummer well.

My patient had the advantage of first-rate trained nurses from the Leeds Nursing Institution, and I wish to acknowledge their care and faithful discharge of their duties, without which she could hardly have escaped the various accidents which are liable to occur in such a case. From time to time I reported her condition to Dr. Allbutt, and he has kindly favoured me with the following criticism:—"As the later history of this remarkable case unfolded itself, of course I gave up the idea of peripheral neuritis. Ascending paralysis (so-called Landry's palsy) was set aside for several reasons, among others the profound anæsthesia, the palsy of rectum and bladder with cystitis, and the age of the patient. It is clear that the disease involved the whole thickness of the cord, including the grey matter, and was probably a myelitis—either an ascending diffused myelitis, or a myelitis ascending in patches. In any case the recovery is very remarkable. The symptoms of returning health in the cord are full of interest."

Dr. Gowers, who has seen my notes, has kindly favoured me with the following criticism of the case founded upon them, which is too interesting and valuable to be omitted. Dr. Gowers remarks on the absence from the report of "some information as to the electric irritability of the muscles at various stages, because this is an important element in the diagnosis." "The diagnosis rests between true acute ascending paralysis and acute ascending disseminated myelitis, and I should incline to the latter, partly on the ground of the cerebral complication, which points to either meningitis or to disseminated inflammation of the cortex. Coincident cerebral and spinal inflammation is not rare, while the brain functions are usually—it is said always—unimplicated in true ascending paralysis. At the same time no malady is sharply defined, and aberrant forms are met with, differing more or less widely from the customary type."

AN UNHEALTHY HOUSE.—At the Nottingham County Court a woman was recently sued for the rent of a cottage in which she had resided. The defendant admitted the debt, but alleged that, owing to defective sanitary arrangements, the place was unfit to live in, and she presented a counter-claim for medical charges and funeral expenses in respect of a child whose death was proved to have been caused by an illness arising from defective drainage. The judge gave judgment for the rent due, and allowed the counter-claim, on the ground that the cottage was not reasonably fit for habitation.

WOUND DIVIDING THE TENDO ACHILLIS AND OPENING THE ANKLE-JOINT.

SUTURE OF TENDON; RESULT.

BY A. G. P. GIPPS, M.R.C.S., &c.

F. S——, a carpenter, was working with an adze on July 30th last, when the tool slipped and struck him over the posterior and inner portion of the left ankle-joint. The result was a transverse wound of about 1½ in. long, dividing the tendo Achillis immediately above its insertion into the os calcis, "nicking" the edge of the tendon of the flexor longus pollicis, and the corner of the adze entering the ankle-joint. There was also considerable bleeding from a branch of the posterior tibial artery, divided close to its junction with the main artery. The patient was a very muscular man and the cut tendon at once receded some distance into the calf of the leg. He was as soon as possible placed under the influence of chloroform, and, the parts having been thoroughly examined, I made an incision two inches and a half long at right angles to the wound, and parallel to the edge of the cut tendon, this being required before it was possible to catch hold of the upper end of the tendon. When this could be grasped by the fingers, it was forcibly pulled down till it was almost in contact with the lower end, when three silver sutures were passed through both ends and secured by twisting. The wounded vessel had previously been secured by torsion; the silver sutures were cut off long. The whole wound and joint were now freely syringed out with a solution of perchloride of mercury (1 in 1000); the skin wounds were brought together with silver wire, leaving only the lowest portion of the wound open, through which were brought the ends of the wires used to unite the tendon, and which served for drainage purposes. The whole wound was well dusted with iodoform, covered with a pad of lint wrung out in the mercurial solution, and the joint surrounded with absorbent wool. The limb was placed on a metal back splint extending above the knee, and the foot secured to the foot-piece in a state of extreme extension, and the patient put to bed.

Aug. 6th: Wound dressed for the first time since the operation (a week). The lint over it was found dry, the wound quite aseptic, and no discharge of any kind present. The upper part of the wound was healed, and all the wires in position. The solution of perchloride of mercury was again used, the wound dusted with iodoform, and the whole replaced as before.—13th: Wound re-dressed. No discharge of any kind. Except at the spot where the inner sutures project, both wounds have united entirely. The skin sutures were removed, and as any attempts to get at the sutures in the tendon only produced a good deal of bleeding from the newly-formed material, these were pulled out as far as possible and cut off short, the small unhealed point being dressed as before.—17th: As the ship was going to sea, the foot was taken down and readjusted, the foot being flexed in order to stretch the tendon. Patient can move the joint himself, and the reunited tendon can be felt in continuity as he extends his foot. There is but little stiffness in the joint itself.—25th: The cicatrix being now firm, everything was removed from the joint, and the patient told to work it freely in bed.—31st: Patient up to-day, and commenced to walk about. He has complete use of the joint as far as movement goes in all directions, and complains only of some weakness and a feeling at present of insecurity.—Sept. 9th: Patient can now walk fairly well, go up and down ladders, &c.

Remarks.—With regard to the temperature, the first two nights it went up to 100°, being normal in the mornings. On the third day it was normal, and remained so for the rest of the time. The bowels were opened on the eighth, tenth, eighteenth, and twenty-fourth days, to avoid all possible disturbance; after that they were allowed to act naturally. With regard to the silver sutures cut off and left in the tendon, so far no effect has been felt from them: firm pressure gives no sensation of "pricking," so they are probably completely buried. The tendon has complete and free play, and the wounded ankle-joint its natural mobility. The treatment by means of the solution of the perchloride of mercury and iodoform proved completely antiseptic, its

Digitized by Google

easy preparation being a great boon in a he patient's confinement to bed he was kept nging cot by an open port.

L, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE CAUSE AND CURE OF A FORM OF BACKACHE.

AMES SAWYER, KNT., M.D. LOND., F.R.C.P.,
CIAN TO THE QUEEN'S HOSPITAL, AND PROFESSOR OF EDICINE IN QUEEN'S COLLEGE, BIRMINGHAM.

the year 1881, in a note which was published in a fessional journal, I asked the attention of my a form of backache which had not, so far as I know, ed before.[1] I desire now to refer to this subject o record that my further experience in practice ed my previous remarks upon the point in ques-

e symptoms are always important diagnostic they are often clear therapeutic indications. ch sensations backache is frequently a leading nd also one which is pressingly dwelt upon by Of backache there are divers forms. Dr. George n an able clinical lecture, and Mr. William practical memorandum, have drawn the attenprofession to many of these.[2] But they have ed a variety of backache in which the cause of traceable to the condition of the large bowel. I me patients complain of a pain, aching, dull, and haracter, and extending "right across the back." d to point out its position, they indicate this by hand behind the trunk and drawing the extended ight across the back, in a transverse line, about etween the inferior angles of the scapulæ and the n. This pain I venture to attribute to a loaded nclude I have correctly found its proximate cause cumulation in the large intestine. I have found it after the exhibition of an efficient cathartic. This ckache is a concomitant of habitual constipation, ecially significant of the alvine sluggishness of persons. In such a condition, as I have stated I find aloes, given in combination with iron, to best results.[3] We owe the valuable suggestion ing iron with aloes, when aloes is given for laxaes, to the late Sir Robert Christison. He showed athartic property of aloes is much increased by ation with sulphate of iron. Dr. Neligan, Dr. der, and Dr. David Bell have confirmed this ex- I prefer socotrine aloes, and I give of it one, two, rains in a pill, combined with a quarter of a grain e of iron and one grain of extract of hyoscyamus. should be taken every night. We must aim at a full alvine evacuation after breakfast. When athartic is indicated, I usually employ the old- Rochelle salt. This "goes" well with tea, coffee, One or two teaspoonfuls may be taken at breakfast, in a large cupful of one of these beverages.

ASE OF COCAINE POISONING.[4]

BY C. S. KILHAM, L.R.C.P., &c.

9th, 1886, at 12.10 noon, John B—— accidentally a. of cocaine hydrochlorate in the form of solution. e was seized with severe cramps in the stomach, robbing and feeling of bursting in his head, yesight, loss of use of his legs, incoherence of confusion of ideas, and drowsiness, but could wer questions if roused. No delirium; appeared as if drunk, and got quite helpless. Brandy was given to him, and he vomited after it, but only the remains of food. About 12.50 he commenced sweating most profusely, shirt &c. being soaked through, perspiration streaming down his face and body, and his head steaming. Pupils were normal and equal. No loss of taste. The sweating lasted some time, and was succeeded by very severe prostration, shivering, and feeling of impending death. At intervals the patient had severe cramps in the stomach, with retching and vomiting of a quantity of clear mucus, which relieved the pain. About 1.15 P.M. the pulse became intermittent (missing every fifth beat). This was accompanied by cyanosis of the face, and intense feeling of suffocation over the cardiac region. Relief was afforded by sinapisms. The pulse varied from 80 to 86, never more, and became gradually regular. About 1.45 P.M. he began to have cramps in the legs and feet (especially on dorsal surface of right foot), and tingling and numbness in both hands. Later on the pupils became dilated. The vomiting and cramps ceased about 4 P.M. (unless food was taken), but the drowsiness, throbbing of head, and prostration continued up to 6 P.M., when the patient began to get warm and feel relieved. The improvement continued, and he could be moved at 8.30 P.M. There was great weakness, with swimming of head all night.

Next day there was still weakness, continual vomiting, a dry leathery feeling in the mouth, with loss of taste, partial loss of power in the legs, and tingling and numbness of the fingers, especially of the right hand. These symptoms commenced nearly thirty-six hours after taking the cocaine, and most of them disappeared in twenty-four hours. The loss of power in the legs lasted three days, and the tingling and numbness of fingers longer. He was not able to write a letter until the sixth day, as he could not feel the pen between his fingers before. An emetic was at first given, with sinapisms over the heart and stomach; afterwards warmth and stimulants (principally compound spirit of ammonia).

Remarks.—The solution of cocaine had been made at least twelve months, but appeared all right. The patient was in the habit of taking ¼ gr. of cocaine for neuralgia of the stomach. The dose taken was 4¼ gr. of hydrochlorate of cocaine. The official dose is up to 1 gr. Martindale, in his book on "Coca and Cocaine, &c.," mentions two cases where larger doses were taken. In one case (of attempted suicide) 23 grs. of cocaine were taken without "seriously injurious effect." In the other case 32 grs. of cocaine were taken within three hours, but the symptoms varied considerably from those in the case under notice. The most remarkable symptoms were the severe sweating, the intense prostration, and the intermittent pulse. The last symptom I have not seen mentioned before.

A CASE OF RETRO-ŒSOPHAGEAL ABSCESS, CAUSING DEATH BY PRESSURE ON THE TRACHEA.

BY PHILIP D. TURNER, M.B. LOND.,
LATE HOUSE-SURGEON, VICTORIA HOSPITAL FOR CHILDREN.

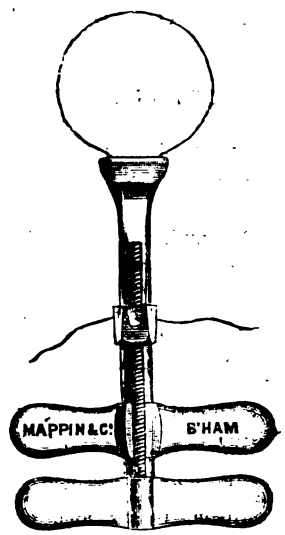
I AM indebted to Dr. Julian Evans for permission to publish this case, which occurred at the Victoria Hospital in April last.

T. H. M——, an infant, aged three months, had been attending the hospital as an out-patient for some weeks for congenital syphilis. It first came towards the end of March with a strongly marked syphilitic eruption, which was followed in the beginning of April by the appearance of multiple subcutaneous phlegmons in the limbs. On April 19th there was an attack of dyspnœa, which passed off in a few minutes. On the 22nd, as the mother was bringing it to the hospital, the child was seized, according to her account, quite suddenly with dyspnœa, and became of a very dusky colour. She hurried to the hospital, where it was at once admitted. There was, on admission, great dyspnœa, with considerable retraction of the thorax; colour very dusky; pulse rapid and feeble; voice not at all hoarse. Hot fomentations were applied to the neck, and the child placed in a steam tent. An hour after admission the respirations became more unfrequent and gasping, the colour very bad, and the pulse scarcely perceptible. Tracheotomy was therefore at once performed. After the operation the child rallied considerably. The recession almost ceased and the colour improved. About three hours later, however, the breathing got worse, the recession increasing again, and

Digitized by Google

a cold sweat appeared on the forehead, the patient becoming very feeble. There was not any great difficulty in swallowing, and the child took milk and brandy with avidity. The symptoms increased in severity, and death took place four hours after the tracheotomy, and about six hours after the onset of the dyspnœa.

Necropsy.—Heart: Left ventricle contracted and empty. Right side flaccid and distended with post-mortem clot. Heart substance and valves normal. Lungs: Marked emphysema of anterior margins and upper lobes. Lower lobes of a dark purple colour, devoid of crepitation; portions cut off sinking readily in water. Liver about normal size. Intralobular veins distended; substance rather tough. Spleen about twice the normal size; friable, but somewhat tougher than natural. Kidneys normal. On endeavouring to dissect out the trachea and œsophagus, the knife entered an abscess cavity on the right of the latter. On further examination, it was found that there was an abscess the size of a large walnut in the areolar tissue behind the œsophagus and lower part of the pharynx. It had no distinct sac posteriorly, being bounded by the bodies and transverse processes of the vertebræ, no disease of which could be detected. The abscess extended from the level of the cricoid cartilage to within a quarter of an inch of the bifurcation of the trachea. On opening the larynx and trachea from the front, no disease could be found in them. The tracheotomy wound was low, commencing about the third ring of the trachea. There was slight flattening of the trachea.



Remarks.—The case appears worthy of record both on account of the rarity of the condition as a cause of death, and of the difficulty of diagnosis in consequence of the low position of the abscess in the neck. A remarkable feature of the case, also, is the almost entire absence of dysphagia. The subject of retro-pharyngeal abscess is treated at some length by Despines and Picot ("Traité des Maladies de l'Enfance"), who state that dysphagia is the most prominent symptom, placing it before dyspnœa. The dyspnœa might be referred to reflex spasm were it not that it returned (with recession of the chest, &c.) after tracheotomy had been performed. Death was probably immediately due to the condition of the lungs &c., as much as to the obstruction. No cause for the abscess was discovered, so it was probably due to suppuration of the post-pharyngeal lymphatic glands which exist in infants, and are, according to Bokai, the commonest cause of retro-pharyngeal abscess. It is interesting to note that the child had suffered from multiple subcutaneous phlegmons only a week or two before its death.

NOTE ON HYSTERECTOMY.

BY LAWSON TAIT, F.R.C.S., M.D., &c.

THIS operation, which only a few years ago looked as if we never should achieve with it the success which alone could justify its continuance, has now, thanks to a large number of small improvements, come within the limits of ranking alongside the operation for removal of ovarian tumours, and, according to my own recent experience, has become almost as successful. It is strange that this success should have been arrived at under conditions almost the exact opposite of those which have contributed to our success with ovarian tumours. In the latter it has been the ligature and its displacement of the clamp which have brought about our triumph. In the removal of uterine tumours, on the contrary, it is the displacement of the ligature by the clamp which has given us the great success.

More than one writer in your columns, in speaking of these operations, has stated that the clamp devised by myself some years ago forms the best method of dealing with the uterine pedicle. This for many reasons I think still to be correct, but there is one reason which makes Kœberlé's form of clamp much superior, and I have therefore discarded my own instrument in favour of Kœberlé's. I have, however, found it necessary to make in the latter two very important modifications, and these seem to make the instrument as perfect as anything we are ever likely to possess. The difficulty with my own clamp is that its power is so enormous that it is difficult to estimate exactly the amount of constriction which it is exercising, and the arrangement, therefore, becomes a difficult one to adjust, specially if it has not been tightened enough, and hæmorrhage should set in a few hours after the operation. At such a time only the nurse may be present, and nurses are not to be trusted to tighten up my clamp. The modification, however, which I speak of in Kœberlé's instrument is one which may be tightened by any nurse, even the most inexperienced, without any risk.

The defects in Kœberlé's original instrument are, first, a movable head, which has an inconvenient habit of dropping off at most inopportune times; and, second, the button upon which the wire is fastened necessitates a twisting of the wire, which loses time and makes it extremely difficult and inconvenient to haul in the slack of the wire, if that should become necessary. I have, I think, completely obviated these two difficulties by making the screw and the head in one piece, and so arranging it that the point of resistance is at the end of the screw, and not in a collar. The new method of fastening the wire is easily explained. It is exactly on the same principle as the cleats of a Canterbury hammer arranged for withdrawing nails. There are two cleats right and left, the wire is firmly bitten in each of them, no loop being in the least necessary, and a slight turn of the wire outwards renders this fastening absolutely secure. I am now in the habit of removing the clamp and wire on the third or fourth day, leaving the pedicle entirely to the care of the needles, and this enables the dressing of the stump to be much more easily effected.

LONDON HOSPITAL.

A CASE OF GENERAL TUBERCULOSIS; NECROPSY; REMARKS.

(Under the care of Mr. FREDERICK TREVES.)

THE following case of general tuberculosis will be found to present several points of considerable interest, and is a good example of a form of the disease. We would draw attention to the remarks by Mr. Treves, especially to those bearing on the etiology of some forms of tuberculosis, the condition of the spine, and of the right knee-joint.

The patient, a young man, aged nineteen, was admitted on Sept. 30th, 1886, suffering from disease of the right knee, paraplegia, and great emaciation. He died on Dec. 6th, 1886. The account of the case can be simplified by commencing with a description of the post-mortem examination.

Necropsy.—The body was extremely emaciated. Five large and deep bedsores had formed over the sacrum and the great trochanter. The former bone was bare. A lymphatic gland in the right groin and another in the left side of the neck had sloughed out, and had left deep holes, surrounded by thin, purple, and undermined skin. There was a general but slight enlargement of the cervical, inguinal, and axillary glands. The right knee-joint was filled with pus. The cartilage was gone over the inner half of the patella, and over both condyles of the femur. It was fairly sound over the tibia. The bared bone was

Digitized by Google

[redacted] The crucial ligaments were destroyed. The joint was flexed, but not dislocated. The other articulations in the body were normal. The left epididymis was converted into a caseous mass. The left testis was nearly wholly caseous, and in the centre was a collection of thick purulent fluid. The right epididymis was caseous, but the right testis appeared to be normal. Both the vesiculæ seminales were blocked with caseous matter. A like material occupied a considerable part of the prostate. The bladder appeared to be in every respect normal. Both kidneys were studded throughout with miliary tubercles. The anterior parts of the bodies of the last two cervical and the first four dorsal vertebræ had been destroyed by caries. The inter-vertebral discs had also disappeared to an extent corresponding to that of the caries. There was no anterior abscess, nor, indeed, was any real pus found in the vicinity of the disease. There was no angular deformity of the column. The spinal canal opposite the affected dorsal vertebræ was occupied by a soft caseous mass. By means of this the cord had been compressed, and in this region it was found greatly softened. Both lungs were studded throughout with miliary tubercles. Here and there was a caseous mass. There were no cavities. There had been slight pleurisy (old) on one side. The peritoneum covering the stomach was dotted over with miliary nodules. It is remarkable that no other part of this membrane was affected. The brain and its membranes were normal, as were such viscera as have not been already referred to.

Clinical history.—The patient was a native of Windsor. His father and mother died when he was young, and he knew nothing of the causes of their deaths. Of four brothers one only is living. Of the other three, one died of a chest affection, one of fever, and a third of abscesses. He had never been strong, and had not been able to follow a definite employment. At the age of fourteen, when walking with bare feet, a rusty nail penetrated the left great toe. An abscess resulted and discharged. The parts did not heal, and at the end of four months the toe was amputated at the metacarpo-phalangeal joint. From this time the patient was never free from suppurative trouble. A few weeks after the operation an abscess formed in the palm of the left hand. Similar abscesses appeared at various parts of the body without intermission from this time. Before one healed another would appear, so that there were usually two present at one time. On admission there were two such abscesses, one on the dorsum of the right hand and one on the neck. They had all the characters ascribed to superficial tubercular abscesses. Before his death the abscess on the hand healed, but another appeared in the groin. Two years ago the patient began to be weak in the legs and to experience increasing difficulty in walking. There were no disturbances of sensation and no bladder or rectum troubles. He became an in-patient of St. Mary's Hospital, where he remained thirteen weeks. Blisters were applied over the dorsal spine, and he was sent out with a Sayre's jacket and a jury-mast. He left the hospital quite well. He wore the jacket for four months, and when he left it off he was able to work. The weakness of the legs had quite disappeared. He remained well in this respect until April, 1886, when the legs again commenced to feel weak. The weakness increased, and by July the patient had entirely lost all power in both lower limbs. At the same time he began to experience difficulty in retaining his fæces and urine.

When admitted into the London Hospital he was very thin, weak, and anæmic. There was complete loss of power in the lower limbs, but no loss of sensation. There was considerable loss of power in the right arm, but no anæsthesia. The patient had lost control over the sphincters. Large bedsores had formed over the sacrum. The right knee-joint was disorganised and filled with pus, and was flexed nearly at a right angle. A swelling had appeared in the left testicle six months previously, and another in the right testicle some three months before admission. Pain was complained of over the upper dorsal spinous processes. The column in this situation was rigid, and presented a trifling projection backwards.

The case admitted of none but general treatment. The patient became weaker and more emaciated. His temperature varied from 99° to 103°. He was the subject of severe night sweats, but had no rigors. He suffered occasionally from diarrhœa. On Nov. 26th he developed a slight cough, which persisted until his death. He died of increasing [redacted] on Dec. 5th.

Remarks by Mr. TREVES.—Without entering upon the vexed question of the pathology of tuberculosis, the case presents certain notable clinical features. In a patient disposed to tubercular disease a simple injury may induce and localise the first manifestations of the trouble. From this primary centre the specific affection may slowly spread to other parts of the body, assuming the mode of progress of a very chronic type of pyæmia. It is allowed that in subjects predisposed to tuberculosis a simple lesion like catarrhal pneumonia may be the initial local factor in pulmonary phthisis. Rabbits appear to be naturally predisposed to tubercular processes, and in these animals the long retention of a simple seton may induce tubercular changes that in time become general and fatal. Moreover, if rabbits be made to breathe an atmosphere charged with atoms of the sputum from a tubercular patient (diffused by spray), and if their joints be contused, those articulations may become the seat of tubercular disease even when the lungs remain unaffected. In the present patient the mischief appears to have been induced by an injury to a toe, and I have no doubt that the subsequent changes in that part that led to amputation were of a tubercular nature. From this primary focus the trouble spread from one part to another. Certain of the superficial lesions underwent spontaneous cure. It is clear that the infection of the lungs, kidneys, and peritoneum were the latest phases of the disease. It is interesting to note that the vertebral affection remained quiescent for nearly two years. The knee became diseased after the onset of the paraplegia; it was never injured, and had long been retained in a position of complete rest. The occurrence of joint affections in limbs, the seat of nerve disturbances, is always a matter of interest. It may be surmised that the paraplegia served to localise the trouble in the knee, and that the relation between the affection in the cord and that in the joint was of a character allied to that assumed by many to exist in the case of Charcot's joint disease. It may be observed also that the weakness in the lower limbs had commenced on the right side, and was more marked in that extremity until the paraplegia became complete. One point remains: The diseased knee was flexed almost at a right angle. The knee disease had not commenced until the paraplegia was complete, and therefore the flexion must have been independent of muscular action. Its occurrence in a paralysed extremity serves to illustrate Braune's experiments of injecting fluid into the knees of post-mortem subjects. These experiments show that the flexed joint can accommodate more fluid than the extended one, and that distension of the cavity leads to flexion of the limb. The flexion in the present instance may be taken to represent that produced by distension alone, for the articulation was filled with pus.

DEACONESSES' INSTITUTION AND HOSPITAL, TOTTENHAM.

CEREBRAL EMBOLISM FOLLOWING PARTURITION, TERMINATING IN HÆMORRHAGE INTO LATERAL VENTRICLE; NECROPSY.

(Under the care of Dr. RUSCH.)

FOR the notes of the following case we are indebted to Mr. Lloyd G. Smith:—

C. C.——, aged thirty-three years, married, was admitted on Oct. 26th, 1886. She complains of weakness of the upper and lower extremities on the right side and giddiness, and is aphasic (of the amnesic type). The illness began two weeks and a half ago. Her father died of a "head affection"; several members of her family are "subject to fits." She is in comfortable circumstances, and of satisfactory habits. Four years ago she was burnt and frightened by the explosion of a fog-signal in the fire, which had got in among the coals; this laid her up for two months. Has had no previous illness. Her present illness began three weeks after her last confinement (ninth), which took place five weeks before admission. The puerperium was quite normal, and lasted two weeks. After being up a few days, she fell while walking along the passage of the house (no known cause—supposed giddiness); was able to get up herself, and suffered no apparent ill effect, but in four days afterwards she had "a fit," the hands being clenched and the mouth drawn to the right side. A streak of blood was seen on the lip. On recovery from the fit her right side was said to have been para-

Digitized by Google

lysed; the face on that side had improved since, while the aphasia remained stationary. Has had nine children; no miscarriages. Two children died, one of measles and one of bronchitis. Labours and puerperia always normal. No specific history.

On admission she had a heavy and vacant expression, but no paralysis of face. She was pale, and well developed, tending to obesity; tongue protruded straight out, but with difficulty; bowels constipated; no abnormal physical signs in alimentary, respiratory, or circulatory systems. Temperature 100°; became normal afterwards. Pupils equal; somewhat dilated; no strabismus. Organic reflexes normal. Patellar reflexes exaggerated on both sides. Slight ankle-clonus. Plantar reflex absent on right side; marked on left. The grasp of the two hands appears to be equally strong. Extremities of right side redder and of higher temperature than those of left. She attempts conversation, but is quite unable to express herself; uses words of few syllables only; time and quantity appear especially difficult to express, her attempts ending with "How stupid I am." Is unable to write her name, but begins first two letters correctly, and then says she "can't see." The case was diagnosed to be one of embolism in the middle cerebral artery or one of its branches, and the treatment was mainly expectant.

The patient's condition remained as above until Nov. 4th, when in the evening she became restless, imagined her child was dead at home, and was depressed and emotional; had a good night. On the morning of the 5th, while taking breakfast, she became suddenly unconscious. The right side was limp and motionless, while the left hand was raised up to her face as if to wipe away something. Right eyeball insensitive. Left ocular reflex normal. Pupils equal at first; later on, right dilated and left contracted. Two hours afterwards the patient became unconscious, the face dark and livid, and respiration ceased, the heart's pulsation continuing a few minutes longer.

Necropsy, seven hours after death.—Vessels of scalp and meninges very congested. Large clot distending the left lateral ventricle; an area the size of a walnut in the left third frontal convolution near the posterior part and in surrounding part of brain, softened into a red diffluent mass, with vessels passing through it. In the middle cerebral artery, at its origin, a large embolus was easily detected. There was effusion of lymph at the base of the brain. With the exception of a small blood cyst on the surface of the liver, all the organs (including the uterus) appeared healthy. No signs of atheroma were found.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

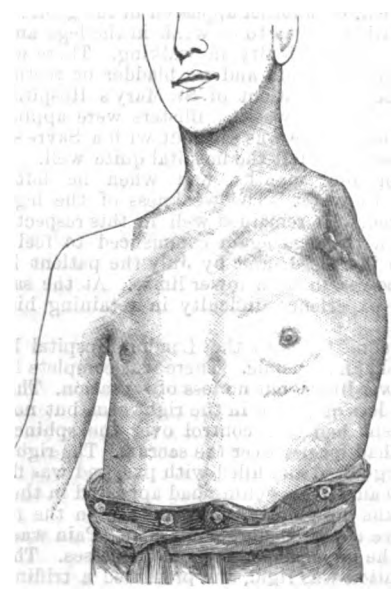
REMOVAL OF THE UPPER EXTREMITY, AND LATER OF THE SCAPULA AND PART OF THE CLAVICLE, FOR SARCOMA.

(Under the care of Mr. PAUL SWAIN.)

FOR the following notes we are indebted to Dr. Buchan, house-surgeon.

Louis G——, aged eighteen years, picture-frame maker, was admitted on Feb. 7th, 1886, for tumour of left shoulder. The patient was a pale, delicate lad, much emaciated, with an anxious expression. The family history and previous personal history were good. He complained that six months before admission he used to be frequently pinched in the left deltoid by a fellow-workman. About two months afterwards he first noticed pain and swelling over the deltoid. This swelling had increased rapidly during the following two months, with great increase of pain. On examination (Fig. 1) there was a large firm swelling involving the whole upper part of the left humerus, and extending somewhat over the scapula and clavicle. The humerus moved with the scapula, almost entirely. There were enlarged veins over the tumour, but no glands were involved.

On Feb. 11th, under methylene, a V-shaped incision was made over the scapula, as if for excision of that bone. However, on cutting down to the joint, the humerus only was found to be involved, and it was removed at the joint. All arteries were tied with chromic catgut, the wound dressed with iodoform and carbolic oil on lint, and a drainage-tube inserted. Morphia and stimulants were freely used from the time of the operation. On the evening of the 12th the temperature was 101·2° F., the highest point. For the first fortnight the wound was dressed under the carbolic spray, by which time it was practically healed.



The patient was discharged cured on March 13th, and had no return of the disease. The tumour was a myeloid sarcoma, arising from the periosteum and causing erosion of the bone.

On April 22nd the patient was readmitted with a recurrence of growth in the left scapula. On April 24th, under methylene, a V-shaped flap was made over the scapula and the whole bone removed, together with the acromial end of the clavicle. Wound dressed as before. A slight skin slough formed at the lowest end of the flap, but with this exception the wound healed rapidly. The patient was discharged on May 27th.

FIG. 1.

FIG. 2.

After recovery from second operation.

Remarks by Mr. PAUL SWAIN.—I regret to say that some weeks after his discharge from hospital the patient caught a severe chill while boating. Pneumonia of the right lung set in, and he gradually sank. (The woodcuts are from photographs kindly taken by Fleet-Surgeon Longfield H.M.S. *Royal Adelaide*).

EDINBURGH ROYAL INFIRMARY.

CASE OF TRAUMATIC TETANUS CURED BY REMOVAL OF THE CICATRIX AND SURROUNDING PARTS.

(Under the care of Mr. J. MONTAGU COTTERILL.)

GEORGE McC——, aged thirty-nine, was admitted on Aug. 2nd with a history of having stabbed the ball of his right thumb with a piece of broken glass on July 17th. Tetanus began to manifest itself on the twelfth day after the infliction of the wound, the first symptom being difficulty in mastication accompanied by pains in the back. As the disease progressed rapidly he consulted his medical attendant, who treated him with Calabar bean (half a grain of the extract every three hours). In spite of this treatment being carried on for four days, the symptoms became more distressing. He consequently applied to the infirmary for advice.

The man's condition on admission was as follows. Trismus was well marked; deglutition was difficult; the muscles of the face, neck, and back were in a state of rigidity; his walk was tottering, and he had to support himself with his hands to avoid falling. He complained of considerable pain in the face, neck, chest, and back. The tongue was moist, white, and furred; the bowels costive. The temperature was slightly subnormal. There was a V-shaped scar, some three inches in length, bluish in colour, knotty, and painless on pressure, situated over the ball of the right thumb.

During the first few days of his stay in hospital he was treated by full doses of chloral and bromide of potassium. This treatment certainly subdued for a time the intensity of the symptoms, though he had frequent spasmodic contractions of the muscles of the back and legs. These spasms could be induced at once by pressure over the ulnar nerve at the bend of the elbow on the affected side, though pressure over other nerves or over the cicatrix itself had no such effect. The application of ice-bags to the spine was tried, but appeared to have a rather prejudicial effect than otherwise. The hypodermic injection of one-fifteenth of a grain of eserine was next tried; this caused alarming cardiac depression, which necessitated very free stimulation for some hours. The eserine seemed to have no effect on the tetanus, and as increased difficulty in deglutition, more frequent and more severe attacks of opisthotonos, and retention of urine occurred, on Aug. 20th Mr. Cotterill freely excised the cicatrix, taking away a considerable slice of the muscles and skin in its immediate neighbourhood. The result was most satisfactory; the patient at once began to mend in all respects, and with the exception of one slight attack of opisthotonos, brought on by the indiscretion of a visitor, he made a rapid and uninterrupted recovery.

Remarks by Mr. COTTERILL.—The interest of the case centres in the fact that though the operation was delayed for twenty-two days after the tetanus set in, and though the central nervous system was seriously implicated, the mere removal of the cicatrix effected a rapid cure. Speaking of this line of treatment, Fayrer[1] says: "I believe that though this treatment would frequently be of service if practised early, it would become useless if resorted to after the disease has become thoroughly developed for even two or three days." Spence[2] also writes: "If the operation be performed at the very first before the symptoms have made any very great progress, the result may be favourable; but after the disease has progressed when the trismus and spasms have become marked, or when the disease has passed beyond stiffness in the neck and difficulty in swallowing,—then amputation will do no good, as by that time the disease has been propagated to the nervous centres." On the other hand, M. Nicaise of Paris says: "Neurotomy is especially indicated when the spasms begin near the seat of injury before their generalisation; but it may still contribute much to recovery when generalisation has occurred by removing the cause which keeps up the spinal irritation."[3] Brown-Séquard writes: "Those who maintain that tetanus, when it has fairly begun, and attacked not only the head but the trunk and limbs, cannot be cured by these operations (amputation and neurotomy), have not read the details of the cases which have been published.....It is most important to give the chance to the patient." Amongst others, Mr. Annandale has reported a case[4] in which a case of acute tetanus affecting the whole system was cured by the free removal of the cicatrix. In the case now reported, though not of the most acute form, the tetanus was decidedly severe, and, in spite of energetic medical treatment, was becoming rapidly worse. Its cure under these circumstances encourages one to operate more hopefully even in what are usually considered unfavourable conditions.

PATHOLOGICAL SOCIETY OF LONDON.

Ulceration and Endocarditis of Right Side of Heart.—Syphiloma of Heart.—Rare Aneurysm of Undefended Space with Cerebral Tumour of Brain (? Syphilitic).—Alcoholic Paralysis.—Ulcers of Stomach in Infantile Tuberculosis.—Epithelioma of Bladder.—Tumours of Testes and Cord.

AN ordinary meeting of this Society was held on the 21st ult., Dr. J. S. Bristowe, F.R.S., President, in the chair. The next meeting will be the annual one, and the new President is to be Sir James Paget, Bart.

Dr. HALE WHITE exhibited a specimen of Right-sided Malignant Endocarditis. It came from a man, aged thirty-nine, who had been ill for four months with rigors. On admission he was found to have a basic systolic bruit, audible chiefly over the pulmonary area and conducted upwards to the left. The rigors continued; the temperature, which was not easily controlled, sometimes reached 105°. The diagnosis of malignant endocarditis of the pulmonary valve was made. At the necropsy the right ventricle was found dilated and hypertrophied. The two anterior pulmonary valves were ulcerated and perforated; a large mass of vegetations sprang from the right one. The liver was fatty; the spleen enlarged; but nothing else abnormal was noted.

Dr. W. PASTEUR showed a specimen of Syphiloma of Heart from a woman aged thirty, who was taken to Middlesex Hospital *in articulo mortis*. She was probably a prostitute. None of the ordinary signs of syphilis were visible except in the heart. The liver had a peculiar marbled appearance. There was some recent lymph on the surface of the left ventricle, which was hypertrophied and dilated. Greyish opaque patches of varying size and distribution were seen in the wall of the ventricle and septum. At least one half of the ventricle was diseased. The right ventricle was less diseased. The patches were ill-defined and translucent at the edges. There were milky-looking patches on the endocardium. Microscopical sections showed infiltration of corpuscular growth, which was very vascular at the margin; the nuclei were spherical and distended. In some of the vessels of the heart doubtful evidences of periarteritis were to be seen, and possibly also of endocarditis. The liver showed numerous accumulations of small round cells, like that met with in some forms of interstitial hepatitis of congenital syphilis.—Dr. CARRINGTON demurred to the syphilitic view of the disease. Why could it not have been an early case of fibroid disease of the heart? The microscopical appearance in the liver was not evidence of syphilis.—Dr. A. MONEY said the specimens were just like those seen in inherited syphilis of liver and heart, and thought that this was in favour of the view that they were syphilitic.—Dr. BARLOW agreed with the last speaker. He spoke of the macroscopical appearance being like that caused by the action of strong carbolic acid on the heart substance and endocardium. With regard to fibroid heart, he asked what was so likely to produce it as syphilis? There was no evidence of old pericarditis, which was a common cause of fibroid lesion of the myocardium. Alcoholism should also be considered in this connexion.—Dr. DAWSON WILLIAMS mentioned a case which nearly resembled that described by Dr. Pasteur. The patient was a boy aged thirteen, who suffered from emphysema and died of bronchitis. At the necropsy it was found that the heart was large and heavy; the pericardial cavity was obliterated over a large extent of surface. In the substance of the heart were numerous nodules. The nodules varied in size from that of miliary tubercle to nodules fully an inch long and half an inch thick. The patient was an only child and had a syphilitic aspect, and the mother had had miscarriages; but there was no direct evidence of syphilis. The changes were sup-

Digitized by Google

posed at the time to be syphilitic, although the appearance on section somewhat suggested sarcoma.—Dr. SIDNEY COUPLAND adopted the syphilitic view because there was no other alternative. He thought the resemblance of the changes to those of inherited syphilis would not be sufficient to remove them out from category of acquired syphilis. It was an infiltrating form, rather than the better known circumscribed lesions of syphilis. Alcoholism as a cause of heart lesions was still involved in obscurity.—Dr. GOODHART argued from the liver to the heart. He had seen such appearances in adults from syphilis of the acute form.

Dr. ANGEL MONEY showed a rare specimen of Aneurysm of the Heart and large Tumour of the Brain, taken from an idiotic female child aged five years. The aneurysm occupied the "undefended space"; its walls were formed by the opened-up laminæ of the septal cusp of the tricuspid valve. All the valves of the heart were in a sacculated or "pouchy" condition, and irregularly thickened. The tumour in the right cerebral hemisphere was of the size of a small orange, and probably gummatous; no bacilli had been found. There were a few fibroid nodules in the right lung, and both lungs were very small and flat. The child was microsomatic, weighed only 13 lb., and measured 31 in. The head measured 18 in. in circumference and 12 in. over the vault from ear to ear. The forehead was almost covered with hair. The child had never walked or talked, and could not even sit up. The anterior fontanelle was still open, and measured one inch and three quarters by one inch and a quarter. There was a loud systolic murmur heard over the præcordia.—Dr. BARLOW thought that the tumour was much tougher than a scrofulous mass, and had a firm chestnut section. The probable very early origin of it was also in favour of syphilis; the evidence of fœtal tubercle was inconclusive. He had seen a specimen of undoubted fœtal syphiloma of the brain. The aneurysm was a unique specimen, and had been shown as such by Dr. Wickham Legg in his Bradshawe Lecture. The question of the origin of aneurysm of the heart in syphilitic changes was a most interesting one, that would repay study. A subacute endocarditis might result from syphilis. He had seen only a second case of aneurysm of the heart in a child in the anterior wall of the right ventricle about the size of a shilling; it was accompanied by mitral stenosis; the syphilitic origin of it was doubtful.—Dr. S. COUPLAND asked whether the aneurysm could have had an origin in an error of development, but deferred to the syphilitic view.—The PRESIDENT asked whether there was evidence of syphilitic disease in the heart.—Dr. MONEY, in reply, said the syphilitic history was inconclusive. He adopted Dr. Barlow's view that the heart changes might have been of syphilitic origin, and possibly that this may have arisen during intra-uterine life. The myocardium showed no sign of congenital syphilis to the naked eye, but it had not been examined microscopically. The presence of bone-thickening in the skull favoured the syphilitic view.

Dr. HADDEN described three fatal cases of Alcoholic Paralysis. The first patient was a woman, aged twenty-seven, who had been drinking to excess for at least four years. For a year before admission her arms and legs had been growing weak. The lower limbs were paralysed and wasted, especially the extensor muscles. The limbs were bent at the knees, and much pain was felt on trying to straighten them. Sensation was unimpaired. The knee-jerks were absent. The muscles were tender, and gave no response to strong faradaic or galvanic currents. There were evident signs of phthisis. On microscopical examination of the spinal cord, it was found to be quite healthy. The myelin of the peripheral nerves had broken up into a finely granular material, and the axis cylinders were quite obscured. The nuclei of the fibres were enlarged. The nerve tubes were irregular in shape, enlarged in some parts, reduced in others, in consequence of the removal of the granular material. The muscles showed an increase in the sarcolemma nuclei and nuclei of the interstitial tissue. In some places there were groups of small round cells, which gave rise to local atrophy of the fibres; slight granular change was seen in some of the fibres, but as a rule the structure was good. In another patient, aged forty-four, who had suffered from alcoholic paralysis for about a month, the spinal cord was found healthy, but the nerves exhibited mixed parenchymatous and interstitial degeneration. The muscles were affected as in the first case. The third case was that of a gentleman, aged fifty-six, who had relapsed after a severe attack of alcoholic paralysis. He was admitted into St. Thomas's Hospital for a deep ulcer on the dorsum of the left foot, opening into the small joints of the toe. He had well-marked paralysis of the legs, with impaired sensation. In this case also the spinal cord was healthy, and the nerves and muscles diseased. There was well-marked phthisis in all three cases. The results of five fatal cases were summed up. The spinal cord was healthy in all. In four of the five the nerves were examined and found degenerated, but in two the change was rather that of a perineuritis. The muscles simply showed increase of nuclei, and occasionally appeared granular. In two cases the medulla was examined and found healthy, and in two the motor convolutions were healthy. The association of phthisis was observed in four cases, and in one the lung mischief was early.—Dr. G. N. PITT, Dr. FINLAY, and Dr. A. MONEY corroborated the statements of Dr. Hadden in regard to the nature of the microscopic changes in alcoholic paralysis.—Dr. BRISTOWE asked whether the changes obtained were more in the distal or proximal parts of the nerves.—Dr. S. COUPLAND referred to the occurrence of peripheral neuritis in association with tubercular disease. Were the changes inflammatory or degenerative? He thought rather the latter.—Mr. A. A. BOWLBY thought the term "neuritis" misleading, for the changes were like those found in Wallerian degeneration.—Mr. H. T. BUTLIN said that sometimes the change might be chiefly in the connective tissue of the nerve. In a specimen of Mr. Savory's there was but little change in the parenchymatous part of the nerve; the case was one of perforating ulcers. The sensory fibres of the nerve were smaller and more affected in some cases than the larger motor fibres.—Dr. HADDEN said that the changes probably began in the smaller nerve fibres, and were less evident in the larger nerves, whilst the anterior roots of the cord were usually free. He rather thought there were sensory changes in some cases of alcoholic paralysis. A considerable thickening of the endoneurium obtained in the sciatic nerve in a case of locomotor ataxy that he had examined. He opined that Mr. Butlin's view might be correct, that in some the changes were more interstitial than parenchymatous. He carefully avoided the discussion of the inflammatory or degenerative nature of the nerve changes.

Dr. BARLOW showed a specimen of Tubercular Ulcer in the Stomach of a child, twenty-one months old, affected with general tuberculosis. It was situate near the cardiac end in the great curvature; had undermined edges, but no thickening around. There were also follicular ulcers at the mid-point of the great curvature, and two near the pylorus. In the first ulcer there was a minute elevation under the mucous membrane, which might have been a miliary tubercle, but had not yet been searched for bacilli. The interest of the case lay in the relation of the small tubercle to the ulcer. Small ulcers of the stomach had been found in adult phthisis. Louis said he had never once seen anything like tubercle in these, and Andral had only once found tubercle of the stomach. Of 146 cases of tuberculosis in children, Barthez and Rilliet found 21 with the stomach affected, and in 7 of these there were miliary tubercles. They had no doubt that the ulcers were caused by tubercle. He had seen two other cases of this kind, but not with miliary tubercle in their base.

Mr. BRUCE CLARKE showed a specimen of Epithelioma of the Bladder. There were two separate tumours. The question was discussed whether the one tumour might have been the cause of the other.—Mr. H. T. BUTLIN mentioned a similar case.—Mr. A. BOWLBY referred to two other specimens in St. Bartholomew's Hospital of multiple growths in the bladder.—Dr. HADDEN had seen an epitheliomatous ulcer of the œsophagus associated with a few other growths in the lower part of the gullet.

Mr. SWINFORD EDWARDS showed specimens of Tubercular and Malignant Disease of the Testis and Spermatic Cord. The first specimen was taken from a man aged fifty; the microscopical appearances were doubtfully those of round-celled sarcoma, and the growth was seen extending chiefly along the vessels. The second specimen was from a man aged forty-five; it began as a painful nodule; the section was obscurely fibrous; it was probably of a tuberculous nature. There were no signs of tubercle elsewhere. The third specimen came from a man aged thirty; it was a round-celled sarcoma of the testis.—Mr. A. BOWLBY referred to the fat and fibrous tissue appearance as of an inflammatory growth in the first specimen, which he thought was not sarcomatous.

The following card specimens were shown:—Mr. S. Paget: Recurrent Epithelioma of the Foot. Mr. Shattock: Hammer

Digitized by Google

Toes. Mr. Targett: Congenital Deformity of Hip. Dr. Beavan Rake: Spontaneous Cure of Thoracic Aneurysm in a case of Anæsthetic Leprosy. Dr. G. N. Pitt: Round-celled Sarcoma of Thyroid growing round Œsophagus and into Left Vagus and Internal Jugular Vein.

HARVEIAN SOCIETY.

Peripheral Neuritis.—Paraplegia in Pott's Disease.—Pityriasis Versicolor.—Dyspnœa from Pressure of Enlarged Bronchial Glands.—Chylous Ascites.

A meeting of this Society was held on Thursday, Nov. 4th, 1886, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

Dr. Buzzard exhibited a patient who had been affected with Paraplegia of neuritic and not of spinal origin. He was a carpenter, and had been exposed to wet and cold in September, 1885. This was followed by pain and weakness, in the right side at first and then in the left, with some tenderness on pressure. In three months' time he had lost power to such an extent that he could not walk; he complained of numbness and tingling, and the soles of the feet were tender. Sometimes also he had tingling in the hands. When seen in March, 1886, he was able to get about on crutches, but did not raise the toes in walking. The knee-jerk was absent. The muscles in the front of the legs did not respond to a very strong induced current, its application not being even felt. The peronei acted slightly, the calf muscles still better, those of the thigh reacting normally. Slight reaction returned in the anterior tibial muscles, a stronger current being required when the negative pole was placed on the muscle. Steady improvement took place. There was slight plantar reflex, but all the superficial reflexes were normal, and the vesical functions were not in any way affected. All portions of the cord, therefore, were probably intact. A large quantity of urine was passed, which contained sugar. Treatment had consisted mainly in the application of the constant current. The patient could now walk a mile, and was still improving. Dr. Buzzard pointed out that the local pain and tenderness, the loss of electrical reaction and of pain in the affected muscles, all combined to indicate peripheral neuritis, while the presence of the superficial reflexes was inconsistent with a lesion of the cord sufficiently grave to produce the other symptoms.

Dr. D. B. Lees exhibited a case for Diagnosis between Peripheral Neuritis and Tabes Dorsalis.—The President thought that in all future cases the possibility of peripheral neuritis should be borne in mind. He thought the new name of neuritic paraplegia was quite justified as descriptive of a fairly common class of cases.

Dr. Hughlings Jackson showed a boy, aged twelve, recovering from a second attack of Paraplegia associated with Pott's Disease of the Spine. The prognosis in such cases was good when rest was enforced. He also exhibited a boy, aged eleven, who had become paraplegic in Sept. 1884, in consequence, it was supposed, of a transverse myelitis. There was no discoverable disease of the vertebræ. He was admitted into the London Hospital, in Jan. 1885, without a trace of movement in the legs, and with extreme rigidity. Not until Oct. 1885 was the slightest movement observed, and then only in the toes. From that time improvement had been steady, but the boy could only now just walk. Dr. Hughlings Jackson remarked on the great length of time during which a patient might remain paraplegic and yet recover, sometimes as long as twelve months. He trusted to rest in bed, not thinking that any drugs or local applications to the spine had any beneficial effect upon the spinal cord disease. He hoped at a subsequent meeting to show both the patients walking well.

Dr. Sidney Phillips showed a case of Pityriasis Versicolor in a child. The boy, aged seven years and nine months, exhibited symmetrical patches of a fawn colour on the chest and back. Scrapings from these examined microscopically were found to consist of mycelium and spores. There was no ringworm of the scalp or any history of its existence.—Dr. Thin threw some doubt upon the diagnosis, and pointed out that the disease was equally uncommon in very old as well as in very young people.

Dr. W. Ewart exhibited a case of Dyspnœa with Metallic Cough and Stridulous Inspiration. The patient, a woman aged thirty-six, had suffered from cough for ten months, at first uncomplicated with dyspnœa. As the cough became more paroxysmal, the difficulty in regaining breath was proportionately increased. Inspiratory dyspnœa also followed upon any severe exertion. The physical signs were dulness in the upper sternal and parasternal regions (especially on the right side), and dulness in the right interscapular region. In all these places there was tracheal breathing, and also in the left upper interscapular region. The patient had had syphilis, and might therefore be the subject of cicatricial bronchial stenosis. This alone, however, would not explain the presence of dulness, which was more probably due to enlargement of bronchial glands, from syphilitic or other cause, which were exerting pressure upon the bronchi, with the above results.

Dr. Robert Maguire showed a case of Chylous Ascites, in a man aged forty-two, who had suffered from œdema of the feet twelve months before admission into hospital, but this had subsided with rest in bed. Nine months later he was seized with sudden pain in the epigastrium, which, though less intense, lasted for five weeks. Two months later the abdomen began to enlarge. There was history of alcoholism, but not of syphilis, and the patient had never lived out of England. On admission there was general distension of the abdomen with fluid, enlargement of superficial veins and of spleen, but not of the liver. Two hundred and twenty ounces of milky fluid were removed by tapping. The fluid was slightly albuminous, contained a large amount of fat and peptones, and did not coagulate on standing. Fat globules, granular matter, and leucocytes appeared under the microscope. In three weeks' time 218 oz. of similar fluid were removed; the fluid did not return, and there was then discovered prominence in the epigastrium, with some increase in the liver dulness. Œdema of the legs still remained. Dr. Maguire diagnosed cirrhosis of the liver, with some inflammatory material behind it, pressing upon the vena cava and the receptaculum chyli, causing rupture of the latter. It seemed very anomalous, however, that lymph, which ordinarily flows under such very slight pressure, should in these cases accumulate to such an extent as to burst both the thoracic duct and the peritoneum.—Dr. Ewart, commenting upon the case, believed that the collective force exercised by the muscular coats of the villi might be sufficient to cause the rupture, although that exercised in each individual villus was very small.

The following is a list of the officers of the Society for the coming year:—President: Mr. Edmund Owen. Vice-Presidents: Mr. T. Bryant, Drs. Cavafy, Buzzard, and John Williams. Treasurer: Mr. G. P. Field. Hon. Secretaries: Drs. Clifford Beale and Handfield-Jones. Council: Drs. W. Ewart, T. Morton, Champneys, Hughlings Jackson, R. S. Mair, R. H. Milson, J. R. Walker, H. W. Page, J. Ernest Lane, C. W. Mansell-Moullin, F. J. Marshall, and A. J. Pepper.

MEDICAL OFFICERS OF HEALTH SOCIETY.

At a meeting held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Friday, Dec. 17th, Dr. Alfred Hill President, in the chair,

Dr. Ashby read a paper on the Contagious Diseases (Animals) Act, 1886, of which the following is an abstract:—The author began by pointing out that the changes effected by this Act in existing statutes had been rendered necessary by the complete failure of the previous Act to produce any effectual control of dairies and cow-sheds. He gave the provisions of the 9th section of that Act, which embodied the 34th section of the Contagious Diseases (Animals) Act of 1878, and which alone affected sanitary authorities. For the purpose of that section, the Privy Council were replaced by the Local Government Board as the central authority. Local authorities in the metropolis were the same as formerly, and in other parts of England and Wales they were now urban and rural sanitary authorities. He pointed out that the wording of the section only conferred on local authorities and their officers a right of entry to any premises between 9 A.M. and 6 P.M., for the purpose of enforcing Orders and Regulations, and not for any other purpose, such as for examining as to the existence of any infringement of Orders or Regulations. He stated that it would be convenient for the officers of the sanitary authority most concerned with duties under the Act to obtain from the local authorities, under the Act of 1878, of their districts a general authorisation to enter any premises in which there was a diseased animal in an infected place. No officers in particular were mentioned, but

Digitized by Google

the clerks of sanitary authorities would be concerned with all legal questions or proceedings arising out of the administration of the Act. Upon inspectors of nuisances would probably devolve the chief part of the work. Medical officers of health would have to advise sanitary authorities on questions arising out of the enforcement of Orders and the framing and enforcing of Regulations. They would advise the inspectors when in doubt, and exercise a general supervision over the administration of the Act. In the event of an outbreak of infectious disease, they would have important duties to perform in making inquiries into the causes of epidemics, and advising such measures as might be necessary to check the spread of disease through contaminated milk. It would behove them to exercise much tact in prosecuting such inquiries, for in the absence of it great injury might be done to persons in the trade. A surveyor's advice would be necessary when important structural alterations were contemplated. Should the work prove to be heavy, the officers chiefly concerned might fairly be entitled to extra remuneration, and, if required, additional officers might be appointed. The Dairies, Cowsheds, and Milkshops Order of 1885, and regulations made thereunder, remained in force; those already made might be adopted by the new authorities, but it might be deemed advisable to revoke them and make new ones. Registers kept by the authorities under the Act of 1878, or copies, were to be delivered to the new authorities. The speaker pointed out that there were no definitions of terms used in the 34th section of the Act of 1878, except "cattle," which meant bulls, cows, oxen, heifers, and calves. "Animals" meant cattle, sheep, goats, and all other ruminating animals and swine. Horses, asses, mules, and dogs were included in certain Orders. "Disease" meant cattle plague, pleuro-pneumonia, foot-and-mouth disease, sheep-pox and sheep-scab. Glanders, farcy, swine fever, anthrax, and rabies were also included in certain Orders. The want of exact definitions of other terms would cause doubt as to the interpretation of parts of the Acts and Orders. It was much to be regretted that this defect had not been remedied in the Act of 1886. It did not appear that any effectual provision had been made to compel defaulting authorities to carry out the Act. Local authorities had to deal solely with occupiers, and not with owners. They could adopt any forms of register or notice they pleased. They and their officers still had no concern with contagious diseases amongst animals, except so far as related to milk from diseased cows. Cowkeepers, dairymen, and purveyors of milk only were named in the 34th section of the Act of 1878. The Privy Council had added much confusion by using in their Order of 1885, without definition, the further titles of "occupier of a milk store or milk shop" and "persons selling milk by retail." That Order required every cowkeeper, dairyman, or purveyor of milk to be registered. Every local authority had to keep a register of such persons, and were empowered to make their own regulations on specified matters. Dr. Ashby next commented on the various articles of the order exempting certain persons from registration, requiring certain provisions for regulating the sanitary condition of new and old cowsheds, and precautions to be observed against contamination of milk. The milk from diseased cows, those ill with cattle plague, pleuro-pneumonia, or foot-and-mouth disease only might not be mixed with other milk, or be sold or used for human food, or be sold or used for food of any animal without being boiled. It would seem desirable that the meaning of "disease" should be from time to time extended so as to comprise tuberculosis, scarlet fever, diphtheria, or any other disease which might be observed to dangerously affect the milk of cows. It might be thought that the Local Government Board should have done this by order, but they had not the power; only the Privy Council could make such an Order under the Act of 1878. The Local Government Board had issued the Dairies, Cowsheds, and Milkshops Amending Order of 1886. It provided a penalty for the enforcement of the Order of 1885. It would have been more acceptable if it could have assigned a definite meaning, in default of the Act of 1886 having done so, to all the terms in the 34th section of the Act of 1878, and in the Order of 1885, which had not been elsewhere defined. Dr. Ashby observed that it was incumbent upon sanitary authorities and their officers to exercise these new powers and duties with due regard to the enormous interests involved, and whilst it behoved them to use all vigilance to diminish human preventable diseases in every lawful way, these remarkably trying times did not admit of landlords and farmers, already hampered, being further harassed through being called upon to reconstruct almost every dairy and cowshed, as would be the case if too stringent regulations were made. Medical officers of health would be called upon for advice in the framing of regulations, and it was most desirable that in their laudable efforts to annihilate preventable diseases they should not be led so far as to annihilate the unfortunate cowkeepers and dairymen instead. The general principles to be kept in view in framing regulations were:—They must adhere rigidly to the letter of the law, they might not go outside the matters in respect of which powers had been given for making them; they must not include anything specifically enacted in an Act of Parliament; and they must not be of too restrictive a character, or repugnant to the laws of England, but must be reasonable, certain, and determinate. The powers for making regulations specifically defined by the 34th section of the Act of 1878 and the Order of 1885 could not be exceeded or departed from in any way. The regulations were of a penal character, and local authorities must not in framing them invent offences. In drawing up regulations, he would say be strong in things really essential for preventing disease; in other things be less stringent. Although they might consider that matters beyond those actually named in the Acts and Order had a bearing on disease prevention, yet they might not be comprised in regulations, because they would be *ultra vires*. Since it appeared to the author that some of those points had not been sufficiently kept in view in making regulations, and that the powers of local authorities had thus been exceeded, he proposed to consider the matters under the several headings of the 13th Article of the Order of 1885, which authorised regulations "for the inspection of cattle in dairies." Under that a regulation giving a general power of entry could not be made, but only one "for the inspection of cattle." It might not provide for the inspection of buildings or premises or animals, as the latter term would include something more than "cattle." The inspection must be of cattle in "dairies" only. That was a most unfortunate term in the absence of any definition. It was evidently intended to signify a dairy farm, but he thought in most districts it would excite the risible faculties of farmers if they were asked to allow cattle to be inspected in their dairies. The use of the term was due to the wording of the Act of 1878. The speaker submitted a set of regulations he had drawn up, from which he had endeavoured to exclude all the points he believed to be *ultra vires*. It was difficult to conceive that the Legislature ever intended that such vast structural alterations as would be entailed by some regulations should be enforced upon the owners of buildings already erected. Their powers were not very satisfactory or well defined, and would remain so until Parliament could spare time to amend such a Parliamentary curiosity of literature as the ninth section of the Act of 1886, and until the Local Government Board should have defined, by Order, the terms in the Order of 1885, if they had power to do so.

The discussion was adjourned until the next meeting.

Sanitary Registration of Buildings.

AT the adjourned meeting of the Society the President, Dr. Alfred Hill, again occupied the chair. The attendance was not so large as on the former occasion.

Dr. C. E. SAUNDERS read the report of the Council, which was as follows:—"Your Council find themselves quite unable to approve the principle of compulsory registration involved in the Sanitary Registration of Buildings Bill, and having given the details of the measure a very full and careful consideration, they regard it as impracticable, and recommend the Society to petition against the Bill, should it be necessary to do so."

The PRESIDENT said that as the Council have expressed an opinion so adverse to the Bill, it would be useless and supererogatory to enter into any further discussion of its clauses and provisions.

Mr. MARK H. JUDGE then made a few remarks in favour of the Bill, and afterwards,

Mr. SHIRLEY F. MURPHY, hon. sec., read a letter from Mr. Ernest Turner, F.R.I.B.A., who regretted his inability to be present. Mr. Turner wrote as follows: "The scheme presented in the draft Bill promoted by the Sanitary Assurance Association is, in my humble opinion, not only totally impracticable, but is also calculated to do much harm to the cause of sanitary progress. The principles of

Digitized by Google

house sanitation are only just beginning to be understood by a few, and the practice is understood by fewer still—although amongst those who have made a special study of the subject any difference of opinion is confined to detail—amongst those engaged in building operations, and amongst sanitary officials there appears to be at present too wide a divergence of opinion even upon general principles to admit of any hope that such a compulsory measure would be satisfactorily carried into effect. As an instance, I may mention the views of the surveyor of a large London parish, who, a short time since, expressed the opinion, at one of the meetings of the Society of Medical Officers of Health, that the public sewers should be ventilated through the drains and soil-pipes of private houses, and that disconnecting chambers were objectionable. Again, I know architects in extensive practice who are still of opinion that the pan-closet is a desirable appliance, and this view obtains amongst some of the officials in Government departments. When we know that even sanitary officials and men of high standing in their profession hold such opposite views, we may fairly conclude that if sanitary reform were handed over to the persons proposed by the Bill, insanitary muddle would be the result. ..... I hope the Society will take the view that the right field of labour is first of all with the sanitary education of the officials who have to administer the laws, and of those to whom the erection of buildings is entrusted, and then the amendment of existing Acts or passing of new Acts of Parliament. The Metropolitan Building Act is ably administered by a body of trained officers, who are not elected to office until they have given proof of their competency to discharge the duties. Surely any comprehensive Sanitary Act such as is proposed would be premature until sanitary education has advanced sufficiently far to provide a similar safeguard to the public."

The motion for the adoption of the report of the Council was then carried, with one dissentient; and on the motion of Professor CORFIELD, it was unanimously resolved that copies of the report be sent to Dr. R. Farquharson, M.P., Sir Henry E. Roscoe, M.P., F.R.S., Sir W. Guyer Hunter, M.P., M.D., and P. Charles Cameron, M.P., by whom the Bill is to be brought into the House of Commons.

ACADEMY OF MEDICINE IN IRELAND.

Narcolepsy.—Myxœdema.

At the opening meeting of the Medical Section on Nov. 19th, the PRESIDENT delivered a short address on some of the circumstances which have prevented a precise knowledge of the Action of Medicine.

Dr. A. W. FOOT read a paper on Narcolepsy (so called by M. Gélineau in 1880) and narrated the case of a youth, aged eighteen, who had been under his observation for three or four years, during which time he was subject to sudden attacks of morbid somnolence, which came on whether he was sitting, standing, walking, eating, driving, railing, or playing the piano. He had no tonic or clonic spasm, retained common sensation, and did not lose consciousness. His personal history was good, but he came of a neurotic family. No treatment availed to relieve him. Dr. Foot referred to two other cases which had been observed in Ireland by Prof. Macnamara and the late Dr. Graves; and concluded by suggesting that the word "hypnolepsy" would be more correct than narcolepsy; that this condition was quite different from the sleeping sickness of Western Africa, and by pointing out the distinction between it and epilepsy.—Dr. HENRY KENNEDY said that in Simpson's Hospital he had frequently observed persons, more or less advanced in life, showing a tendency to fall asleep under unusual conditions—for instance, at dinner. He considered this tendency to be due to the blood being overloaded with the purest kind of fat, as described by the late R. Smith.—Mr. CORLEY mentioned a case which he had had under treatment that agreed in every respect with the description of the disease given by Dr. Foot. Three or four years ago a dairyman's labourer was admitted into the Richmond Hospital. He had some months before fallen from a dairy cart on the back of his head. While eating he suddenly let his knife and fork fall and went to sleep. He had evidently cerebral pressure. His family history suggested that he had something in the nature of a tumour, probably out of reach of the surgeon's knife. The case had a fatal result. Dr. Abraham made a post-mortem examination, which confirmed this diagnosis. There was a small abscess, twice the size of a walnut, in the posterior right lobe of the cerebrum; and no doubt the symptoms depended upon that. The striking similarity in the symptoms described by Dr. Foot indicated that some part of the cerebrum was affected in his case also.—Dr. C. J. NIXON had recently seen a member of his own profession who was suffering from attacks like angina pectoris. Close on sixty years of age, the gentleman in question had been for several years, whilst in the Army Medical Service, subject to sudden attacks of periodic sleep at extraordinary times, even on duty. The intervals between the attacks greatly decreased, and he was obliged to leave the service.—The PRESIDENT said he had seen only one such case—that of a powerful young man, aged twenty-seven or twenty-eight, who managed successfully a great business in the city. He was of a family in whom neurotic affections abounded consequent on close intermarriage, his father and mother being first cousins.—Dr. FOOT, in reply, said he was aware of Smith's observations on fat and free oil, which that writer had used not in connexion with extreme tendency to sleep, but with fatty degeneration of the viscera, and thus he had described free oil flowing out of the body. Sleepiness at meals had nothing to do with narcolepsy. A good dinner, a warm fire, and a comfortable chair invited sleep. Following Gélineau and Dana, he had used the word "neurosis." One of Gélineau's patients, who was a soldier, had started a nice medico-legal question, "What would become of me," he asked, "if the sleep attack came on me whilst I was on sentry or on guard? I should be shot, and not for any fault of mine."

Dr. C. J. NIXON read a paper on a case of Myxœdema, having previously exhibited the patient.—Dr. M'SWINEY said the paper proved, as also did a recent case operated on by Sir William Stokes, that the crucial experiments performed by the surgeon often disproved theoretical conclusions which were the result of mere observation.—Sir WM. STOKES said his case was that of a female with a rapidly increasing bronchocele. Owing to the mechanical effects of pressure of the tumour, he deemed it necessary to relieve her. The operation consisted of two parts. He first removed the left lobe of the thyroid gland as the largest of the two. The wound healed, and the patient perfectly recovered. After a considerable interval she presented herself again for admission into hospital. The tumour on the right side having undergone remarkable diminution, increased rapidly, and gave rise again to the serious symptoms referable to mechanical pressure. Thereupon he removed the remaining lobe of the thyroid. The wound completely united, and the patient seemed to go on favourably till the remarkable symptoms detailed in Dr. Nixon's case supervened—pallid face, puffy eyes, and swelling about the wrist and ankles, which pitted on pressure, while the intellect became impaired, as indicated by the length of time it took her to answer a question. At length, as the symptoms became urgent, she had convulsive seizures, somewhat epileptiform, respiration became difficult, and she expectorated large quantities of mucus—these conditions increasing till she died from exhaustion. He had little doubt there was a distinct connexion between the complete removal of the thyroid gland and the symptoms which subsequently developed. Still, he would not take a gloomy view of the future of thyroidectomy. There had been a large number of cases of removal of the thyroid gland unattended by the development of myxœdema.

MANCHESTER PATHOLOGICAL SOCIETY.

A MEETING of this Society was held on Wednesday, Dec. 8th, 1886, Dr. J. Dreschfeld, President, in the chair.

Broncho-pneumonia in Children.—Dr. H. ASHBY showed the lungs of a child who died from broncho-pneumonia.

Epithelioma of the Tongue.—Dr. W. THORBURN showed a number of sections of an epithelioma of the tongue, which had apparently developed from an ulcerating gumma. The sections, being cut continuously, demonstrated the method of growth and invasion of the tumour.

Diaphragmatic Hernia.—Mr. A. H. YOUNG exhibited a preparation of a case of diaphragmatic hernia, which had been discovered in the dissecting room. He pointed out the impossibility of diagnosing such a case during life.

Surgical Kidney.—Mr. C. E. RICHMOND showed specimens of surgical kidney, together with the bladder and ureters. The bladder was chronically inflamed, much dilated, hypertrophied and fasciculated. The ureters and pelves of the

Digitized by Google

kidneys were dilated and inflamed, and contained a mixture of foul urine and pus. The kidneys were enormously enlarged; the whole parenchyma was macerated in pus, and the capsules separated easily. There were large perinephritic abscesses. There had been a history of chronic retention, with much ropy mucus in the urine. Death had occurred from uræmia after the use of the catheter. There was no stricture or prostatic disease; hence it was inferred by Mr. Richmond that retention and consequent dilatation of the bladder had been due to the obstruction caused by ropy mucus.

Phosphatic Intestinal Calculus.—Mr. A. H. YOUNG showed for Mr. Wren, M.R.C.V.S., an enormous calculus found after death in the large intestine of a pony.

Dr. J. DRESCHFELD gave an account of some recent researches on thrombosis.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AN ordinary meeting of this Society was held on Nov. 8th, Mr. Edward Atkinson, Vice-President in the chair.

Mr. MAYO ROBSON showed a specimen of Hydrosalpinx which he had removed from a patient ten days previously. She had had pelvic pains which prevented her from working for several years. The patient was recovering.

Mr. ROBSON also exhibited a specimen of Ruptured Jejunum, caused by a fall from a scaffold. The man presented no external signs of injury, but had symptoms of intestinal strangulation and peritonitis, for which laparotomy was performed.

Mr. W. H. BROWN showed a Ruptured Bladder, apparently spontaneous, for there was no history of injury. The patient survived four days.

Mr. EDWARD ATKINSON showed a patient from whom he had excised the Sternal End of the Clavicle for dislocation upwards. The man, who before the operation was unable to use his arm, had now a very useful limb.

Mr. MAYO ROBSON brought forward a patient, twenty years of age, in good health, on whom he had performed Supra-pubic Lithotomy three weeks before, the interesting feature of the case being the suture of the bladder and primary union of the wound.

Oöphorectomy.—Mr. W. H. BROWN read notes of a case of Oöphorectomy undertaken for indefinite nervous symptoms, which had existed for ten years, and which were chiefly referred to the pelvis. During the whole period the patient had been attending some charitable institution, and the operations of stretching the sphincter ani and the urethra and scooping out the uterus had been performed in vain. The last operation, in which normal ovaries and tubes were removed, was also without effect.—Dr. BRAITHWAITE thought the case was not a proper one for oöphorectomy.—Mr. WHEELHOUSE considered it unjustifiable to perform such operations for such indefinite symptoms.—Mr. MAYO ROBSON thought it was very seldom justifiable to remove healthy ovaries, as in the operation known as Battey's; but he was quite sure that a great advance had been made in surgery by the removal of diseased uterine appendages known as Tait's operation. He had operated on a number of cases of pyosalpinx and hydrosalpinx with great benefit, and as yet with no mortality. He always had a full consultation on the case previously, and explained the nature of the operation fully to the patient.

Removal of Ingrowing Eyelashes by Electrolysis.—Mr. BROADBENT HEWETSON described this method, and showed the apparatus. The needle attached to the negative pole was inserted for twenty seconds.—Mr. SNELL referred to a paper in which he had described this operation three years before. He had used the method for removing superfluous hair on the face in females, and in one case he had removed a moustache from a young lady.

Cataract.—Mr. SNELL read a paper on the Treatment of Cataract and other eye operations, to the exclusion of dark rooms, bandages, &c. He referred to his article in THE LANCET, of Sept. 18th, and said that experience had taught him the value of plaster as a means of closing the eye as superior to the method by bandage. He had used the method in fifty-three cases, thirty-two being operations on the lens, the remainder being iridectomies, iridotomies, sclerotomies, and operations for anterior synechiæ. Reference was made to its utility in injuries of the eyeball, and in other cases where it was desirable to keep the eye at rest. He explained the method of cutting the plasters, which was that known as "salicylated isinglass plasters."

Hemiplegia.—Mr. J. W. TEALE read notes of a case of a lady of sixty-four, who, after prolonged and obstinate constipation with albuminuria, was seized with hemiplegia on the left side, accompanied by convulsive movements of that side. In the deep unconsciousness which followed the attack (lasting fifty-four hours) the sphincter ani was stretched. This was followed by copious action of the bowels. The patient recovered a considerable amount of movement, and the albumen was reduced to a trace.—Dr. HUTCHINSON remarked on the great difficulty of estimating the value of remedies in nervous disease.—Mr. T. P. TEALE described cases of rigid sphincter without spasm, giving the sensation to the finger of a cartilaginous ring, and relieved by stretching.—Mr. FLETCHER LITTLE remarked on the less frequent occurrence of obstinate constipation among French women, due to the more general use of enemata.

Dr. ERNEST JACOB showed a Papillomatous Tumour which he had removed from the larynx of a young man, where it greatly interfered with the voice. It was a return growth, the first having been removed by him eight months previously. He showed various forceps used in such operations, and remarked on the value of endo-laryngeal operations over thyrotomy.

Dr. GRIFFITH exhibited the temperature chart from a case of Enteric Fever, showing two complete relapses, each of three weeks' duration.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on Wednesday Dec. 8th, 1886, Mr. Lloyd Owen, President, in the chair.

Radical Cure after Strangulated Hernia.—Mr. BARLING showed a man aged thirty-five on whom he had operated for congenital inguinal hernia eighteen months ago. At the operation blood was found in the sac and walls of the intestine, in which there was also a slight laceration. After the strangulation was relieved a tunica vaginalis was made from the lower part of the sac, and the upper part was ligatured and left in the inguinal canal. Two short wire sutures were then passed through the pillars of the ring and walls of the inguinal canal; these were tightened up and cut short. The wound healed by first intention; the patient got up with a truss on in three weeks, and has since worn a truss, until a month ago, when he was instructed to discard it. At the present time there is no return of the hernia, and the external ring is tightly closed; the wire sutures can be felt *in situ*, the testicle feels normal, and slides easily in its tunica vaginalis.

Fœtal Abnormality.—Mr. A. F. HAWKINS showed an eight months' fœtus which presented the following abnormalities: the umbilical cord was 2½ in. long; there was ectopia abdominale, the lining of the bladder being covered with a mass of meconium. The intestine opened into the left upper corner of the bladder, there being no distinction between the large and small gut; the penis was undeveloped, imperforate, and above the pubic arch, the latter being incomplete, and the halves joined by a ligamentous band. The scrotum was divided, the right testicle lying loose in the abdominal cavity, with a stalk about an inch long; the left testicle was in front of the left kidney under the peritoneum. At the back a large cyst extended from the angles of the scapulæ above to the buttocks below; it was in the median line, about the size of a tennis-ball, and was lined by a smooth vascular membrane; this contained a perfectly clear limpid fluid; no nerves stretched across it. In the anterior portion were two depressions, one the size of a crowquill, ¼ in. in depth and apparently blind; the other, which was higher, was an opening with circular and well-defined edges ¼ in. in diameter; a probe could be passed through this upwards into the vertebral column. Both feet were clubbed; the hands were normal.

The Leg Type of Progressive Muscular Atrophy.—Dr. SUCKLING exhibited a woman, aged forty, suffering from Progressive Muscular Atrophy, which had commenced in the feet and legs. There was marked emaciation of the leg muscles, the feet being dropped, inverted, and useless. The gait was of a "high-action" or "equine" character, and the knee-jerk was lost. The thenar and hypothenar eminences of both hands were wasted, and the *main en griffe* was present. The "reaction of degeneration" was also present in the tibialis anticus, extensor longus digitorum, and peronei in both

Digitized by Google

legs. The patient's two sisters were affected in an exactly similar manner, and her uncle and father suffered from wasting of the legs.

Chevet's Disease.—Mr. CHAVASSE showed a case of Chevet's Disease in the ankle of a man who some years previously had his thigh amputated for some disease of the knee.

Dr. C. J. LEWIS read a paper entitled "Clinical Observations on Syphilis of the Larynx."

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held on Friday, Dec. 3rd, at which twenty-two members were present.

Dr. KERR showed the following specimens, with notes of the cases:—1. Case of unexpected Hysterectomy, in which abdominal section was made to remove a pyosalpinx. During the operation a small subperitoneal myoma was also removed. The pedicle was secured by the Staffordshire knot. During the tightening of the ligature the peritoneal coat of the uterus was fissured, from which a slight oozing of blood took place. This was stopped by sponge pressure, and the operation was completed, a drainage-tube being left in. Finding that the bleeding continued, the abdomen was again opened in the evening, and, the actual cautery and continuous suture proving ineffectual, hysterectomy was performed. The patient made a good recovery. 2. Two Diseased Ovaries: one an example of a very small multilocular cystoma; the other a cirrhotic ovary removed from an unmarried woman, who had been almost entirely disabled for five years. 3. A section of Diseased Mammary Gland, which proved to be malignant, and an Axillary Gland, likewise affected, from a patient otherwise in better health than she had been for years. There was only a seven months' history of the growth. 4. Uterine Polypus, three-quarters of a pound in weight, separated from its connexions by the écraseur, and delivered by midwifery forceps.

Dr. HANDFORD showed a boy, aged nine, in the early stage of Pseudo-hypertrophic Paralysis. Difficulty in walking was first noticed at five years of age; he has had several fits; the mental faculties are deficient. No other members of the family have had a similar affection. Patellar tendon reflex was absent; electro-sensibility was unaltered; electro-contractility to both currents much diminished and delayed. Dr. Handford showed photographs of a second case. They were taken in 1882, and the boy was then aged eleven. His elder brother died two years ago of the same disease. In November, 1886, this boy was again seen and found to be much grown and well nourished, but unable to stand or raise his legs when lying in bed.

Dr. HANDFORD exhibited photographs and coloured drawings of two cases of Pemphigus, and one of Hydroa Herpetiforme. In one of the cases of pemphigus attention was called to a marked pigmentation of the skin, and to a very unusual condition of the cicatrices left by the bullæ.

Mr. W. T. CARR, read a paper upon Anæsthesia and Anæsthetics. An interesting and prolonged debate followed, which was adjourned to a special meeting.

THE GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE third meeting of the session was held in the Faculty Hall on the evening of Dec. 22nd. Drs. W. W. Anderson, R. H. A. Whitelock, Skene Keith, F.R.C.S.E., and S. George Campbell were admitted Fellows.

Injury in Twin Pregnancy.—Dr. GLAISTER exhibited (1) a Typical Battledore Placenta, and (2) a Placenta and Fœtus, illustrative of the effects of injury in a twin pregnancy. In this case the mother when three months and a half pregnant with twins had a severe fall, which caused the death of one, the cephalic extremity of which presenting along with the head of the other at labour caused some dubiety as to twins or to what it could be. The fœtal remains exhibited within inches of cord attached showed signs of post-mortem inflammatory action, one of the feet being found attached by lymph deposit, in the form of a band, to the body, as were further lymph formation. The placenta was in one mass, but divisible into two portions; one, the larger, containing ordinary healthy placental tissue, and the smaller being markedly white. There was one chorion and one amnion.

Dr. R. POLLOCK exhibited a fœtus which bore signs of maceration.

Dr. W. L. REID exhibited the Head of a Fœtus which he had extracted after Basilysis, and a discussion ensued as to the respective merits of basilysis and cranioclasm, or craniotomy. The balance of opinion was against the former.

A Review of Thirteen Years' Private (Obstetric) Practice.—Dr. J. K. KELLY read a paper on this subject. Guarding himself, firstly, by stating that his results, owing to the imperfections not only inherent in every recorder, but also due to the conditions of general practice, must be regarded as approximately and not absolutely correct, he said he had attended, between the years 1873-85, inclusive, 2823 confinements, at which 2868 children were born. In all these the maternal mortality had only been seventeen, or one in 166. Five of these were due to causes unconnected with parturition, thus reducing the true childbed mortality to one in 235·2. Taking the last six years only, the maternal mortality had only been one in 411. In 762 primiparæ, the mortality was eight, or one in 95½, and in 2061 pluriparæ, nine, or one in 229. But in his last six years practice he had 284 primiparæ, with no deaths, and 949 pluriparæ, with three deaths. The paper was full of scientifically interesting statistics, was listened to with great interest, and the discussion upon it was adjourned.

Reviews and Notices of Books.

The Parasites of Man and the Diseases which proceed from them. By RUDOLF LEUCKART. Translated from the German by WILLIAM E. HOYLE, M.A. Oxon., M.R.C.S., F.R.S.E. Edinburgh: Young J. Pentland. 1886.

THERE is no more interesting subject in natural history than that of parasitism. It embraces the whole of the animal and vegetable kingdoms, and illustrates in a remarkable way the laws of adaptation. In relation to mankind, the subject has, moreover, a special interest for the medical profession, for it not only explains the origin of certain obscure diseases and points the way to the prevention of others, but it embodies a doctrine which is capable of being most widely applied. For the "term 'parasite'"—so runs the opening sentence of the work before us—"in its widest sense includes all those creatures which inhabit a living organism and obtain nourishment from its body." This definition is wide enough to take in all the bacterial organisms that modern investigations have shown to play so important a part in the etiology of disease, and at present we are doubtless far from embracing in our view the whole range of their activities. It is, then, all-important that we should be well instructed upon the subject of parasitism, and yet it is a subject which has attracted the study of comparatively few. In the late Dr. Cobbold England lost almost her only exponent of the subject, for he was one who had devoted time and labour to its investigation. His great work on the Entozoa remains as a monument of his industry, which was further shown in the numberless monographs upon special branches of helminthology that he contributed from time to time. But even Cobbold would admit that the work of Rudolf Leuckart was greater than his own, and it is therefore with peculiar gratification that we welcome the appearance of this classical treatise in an English dress. Professor Leuckart is a naturalist, and he deals with the subject from the point of view of a naturalist, but this is no disadvantage; on the contrary, it is a real gain, since he clearly traces the origin and nature of the various forms of parasites, and dwells upon their distinctive features in a way that not only imparts new knowledge, but also points to the most effectual means for coping with these unwelcome guests of the human body.

The bulky volume before us does not comprise the

Digitized by Google

whole of Leuckart's great work. It contains a general account of the natural history of parasites, and a special description of all the forms from protozoa to cestoda. The second volume, which will include the nematode and trematode helminths, as well as the arthropod ectozoa, is at the present time appearing in the second German edition; and Mr. Hoyle tells us that the translation will proceed *pari passu* with that publication. The English edition has also had the benefit of further revision by the author himself, who contributes to it a preface. The work is confined to *animal* parasites. These, we are told, are either "occasional" or "constant," the former varying their habitat according to circumstances, and forming a link between the true parasite and the free-living animal. Then, as regards their relation to their hosts, parasites may be "temporary" or "stationary," terms which explain themselves; and the stationary forms may be "permanent" in their attachment, or "periodic" and wandering. Many examples of these varieties must be familiar to all; and what is of especial interest is the fact that the more stationary a parasite is, the more does it lose all the features characteristic of an independent animal organism. It becomes degraded in type, and assumes more the form of an appendage to its host than a separate individual. A very interesting chapter in this connexion is that upon the origin of parasites, where the author traces the changes undergone in organisms that depart from the nature of free-living beings to become dependent upon others for their sustenance, retaining often (e.g., trematodes) in their larval state the attributes and powers of the independent creature. The effects produced by parasites upon their hosts are multifarious, depending for their gravity largely upon the situation which is selected by the entozoon for its habitat, as in the case of Cœnurus cerebralis, Syngamus trachealis, or the Strongylus equinum that infests the mesenteric arteries of the horse, leading to aneurysm; or else depending on the injuries inflicted by them upon the body, as in the case of Dochmius duodenalis, which not only extracts blood for its own nutriment, but is the cause of intestinal hæmorrhage and a fatally progressive anæmia. Nor need we do more than mention the agency of such parasites as Bilharzia hæmatobium, Trichina spiralis, Tænia echinococcus, and the hæmatozoon Filaria sanguinis hominis, with which medical literature is now so fully familiar. From general considerations such as these we turn to the detailed and systematic account that forms the bulk of the volume. It is here that the reader will be especially struck by the thoroughness and knowledge which the author brings to his work. A large number of protozoic organisms are described, the majority of which are of but slight importance; but the attention of the pathologist should be especially directed to the gregarines or sporozoa, of which the coccidia infesting the liver of rabbits and mice are perhaps the most striking examples. Man also may be infested by these minute organisms, probably by contamination of food through the excreta of the rabbit. A fatal case in a man, marked by enlargement of the liver, is recorded by Gubler; and drawings are given of coccidia from the human liver from another case. Several infusoria occur in the intestinal canal, the Balantidium coli discovered by Malmesten in 1856 being one of these. It occurs in the pig very abundantly, as well as in man; but it is interesting to note that it has only been found in cases where the intestines are already diseased. The cestode worms receive, commensurate with their wide distribution and importance, a very large share of attention their remarkable metamorphosis and life-history preceding the special anatomical description of each genus. Here will be found a full discussion of the views of other writers and the records of the author's own work, which have thrown such a clear light on the history of these organisms. The Tænia saginata (better known in this country as T. medio-canellata), perhaps the most common, is first described, and then Tænia solium, with its larval cysticercus. Later we meet with an ample discussion of the Tænia echinococcus, and then of the interesting Bothriocephalus latus with its ciliated embryo, and the much-debated question of its intermediate host.[1] The zoological account is followed in each instance by sections upon the distribution and medicinal significance of the tapeworm under consideration.

Such, then, is the scope of a work which, holding the first rank among treatises upon the subject, is to be welcomed as a great addition to our literature. It is a book to be widely read and studied, and we may congratulate both Mr. Hoyle upon the excellent translation which he has effected, and his publisher for presenting the volume in so attractive a form, with the numerous illustrations that add greatly to the interest and value of the text.

The Diseases of the Prostate; their Pathology and Treatment. Comprising the Jacksonian Prize Essay for the year 1860. By Sir HENRY THOMPSON, Consulting Surgeon and Emeritus Professor of Clinical Surgery to University College Hospital. Sixth Edition. London: J. and A. Churchill. 1886.

THIS work is so well known that we are absolved from the duty of doing much more than noting the fact of the publication of a new edition. Some of the chapters show signs of revision and addition, but for the most part it is a reprint of the former edition. Four new illustrations have been added. One notable change in the nomenclature is to be observed. We no longer read of "hypertrophy of the prostate," but of the "enlarged prostate of elderly men." Sir Henry Thompson does not think that the contour of the prostatic urethra can be modified by the passage of instruments, and he leaves his readers to infer that he does not believe that the passage of soft bougies will prevent the obstruction of the canal by outgrowths of this organ. In the cases of this disease where life is rendered a misery by very frequent and painful efforts at micturition, in spite of the proper use of the catheter, the draining of the bladder by an incision into the membranous urethra is recommended in preference to epicystotomy, which Sir Henry Thompson previously advised. We do not think that sufficient importance is attributed to the effects of the atony of the bladder so often associated with chronic enlargement of the prostate. There is much to show that in a large number of cases the symptoms are really the outcome of the atony rather than of the hypertrophy, and that the benefit obtained by daily catheterism and emptying of the bladder is to be explained by the recovery of power in the bladder which this causes.

The more recently recorded cases of malignant disease of the prostate have been added to the table of cases of this disease but cancer is stated to be more common than sarcoma. We doubt the accuracy of this view. It is more than probable that, as in the testicle, *all* the cases of malignant disease of the prostate in children are cases of sarcoma, although recorded originally as cancer, and some of the cases in adults which have been described as "medullary cancer" have probably been sarcomatous in nature. The chapter on Tubercular Disease of the Prostate opens with this sentence: "The prostate is very rarely the seat of the tubercular deposit," whereas "prostatic cancer" is spoken of only as "a rare affection." Surely these expressions do not represent the facts with sufficient accuracy. As a primary disease tubercle of the prostate is no doubt very rare, even if it ever occurs, but we have often observed the prostate enlarged secondarily to tubercular disease of the testicle, and Curling writes that the disease in the testicle is "often associated with

[1] Leuckart holds it to be the pike and turbot, but has failed to prove this experimentally.

ionnaire de Médecine et de Chirurgie Pratiques. : Zym. Supplément. Table Analytique. de la Rédaction le Dr. JACCOUD. Paris: ère et Fils. 1886.

e completes the Dictionary, and we may make l observations upon its scope and character. is kind may belong to one of two types. It give short explanations of every important t under such a term as "anæsthesia" the find the etymology and explanation, or the haracters of anæsthesia may be included under term, such as "nerve" or "nervous system," or " or "sensibility." Each method has its advan- disadvantages. If a reader meet with a term he is unacquainted, he has only to refer to his he finds, if it be a good one and framed on the a brief and explicit account of it; but the f course completely isolated and unconnected. hand, a dictionary constructed on the second gh it renders it difficult for the reader to meaning of a particular term unless the index arily good, yet supplies the busy man with a rustworthy and, if we may use the term, read- of the various diseases; and if he have time to y such articles, he can make himself acquainted ecently introduced words and phrases, and imself with the existing state of medicine and e Dictionary before us belongs to the latter e feel bound to state that, owing to the the contributors and the care which has d upon the several articles, the purchasers k will find that they obtain a thoroughly equivalent for their money. It was com- 1864, and has been published with much t the rate of about two volumes a year. The deaths amongst the contributors, considering e that has elapsed since the first volume was has not been great. It includes, however, the d names of Demarquay, Gintrac, Hirtz, Laugier, Nélaton, Maurice Raynaud, Amb. Tardieu, Trousseau, ite recently one of the most original and hard- coadjutors, Paul Bert, whose too early death regretted by all who have an interest in the ad- t of science. The Dictionary has been published markably cheap price of seven shillings and sixpence me; and considering that each volume makes about undred pages, it contrasts favourably with any American, or German work of a similar character. ve in our notices of the several volumes as they peared called the attention of our readers to the l articles, it is unnecessary that we should recapitu- remarks previously made. In respect of the present it is to be regarded as a supplement containing several such as Microbes, Chloral, Jequirity, Cocaine, and ich have either been accidentally omitted or which into being or into general use subsequently to the the articles having the same initial letters were The work terminates with an accurate and very complete Analytical Index by Dr. Decaye. Great praise is due to the able editor, M. le Docteur Jaccoud, for the admirable manner in which the editing has been accomplished. The general arrangement of the articles is excellent. The typographical errors are few in number and trivial in their nature, especially in regard to the spelling of the names of English and German authors, in respect to which the French are, as a rule, extremely careless, in proof of which we may just observe in passing that we saw in a work of repute some time ago Faraday referred to as Professor "Farrhadouy." We must not conclude our observations without a word of praise to MM. Baillière et Fils, for the good paper, clear print, and excellent illustrations with which the work has been published. Those who desire a good French dictionary of medicine and surgery cannot do better than place a copy of the "Dictionnaire de Médecine et de Chirurgie Pratiques" on their bookshelves, and consult it whenever they have the misfortune to meet with a rare, a refractory, or an inexplicable case.

Analytical Records.

BENGER'S PEPTONISED CHICKEN JELLY.
(MOTTERSHEAD & CO., MANCHESTER.)

MR. BENGER'S preparations are now so well known, that all we need say of the sample before us is that it is excellent. It has a delicate chicken flavour, free from the bitterness which used to interfere with the employment of peptonised articles. We gave some to a patient in a critical stage of recovery from typhoid, and found that it was taken easily.

CARNRICK'S LIQUID PEPTONOIDS WITH COCA.
(CARNRICK & CO., LIMITED, HART-STREET, LONDON.)

Like the preparation noticed above, this is only a new adaptation of a well-known and highly esteemed article, The idea, which seems to have been successfully carried out, was to unite the powerful nerve stimulant coca with an equally powerful and easily assimilated food stimulant.

FINEST MONING GLENELG TEA, 1884-85.
(T. F. ALLEN, CHURCH-PASSAGE, GUILDHALL.)

Small clean leaves, quite free from adulteration; delicate flavour. Analysis gave the following percentages:—Ash 6·27. insoluble ash 2·83, alkalinity of ash (as KOH) 1·32.

FINEST MONING GLENOGLH TEA, 1886-87.

Closely resembles the last, but with somewhat smaller leaf. Is a very fine tea. Analysis:—Ash 6·59, insoluble ash 2·65, alkalinity of ash 1·23. It will be seen that there is no important chemical difference between the two samples.

VOLTMER'S ARTIFICIAL HUMAN MILK.

This preparation deserves to be given an extended trial, by which method alone can its value be determined. It has for five years met with some success in Germany. There is no doubt of its containing the necessary principles of food. It is sold in packets that look something like soft toffee or butter-scotch. One of these makes half a pint of milk. The cream rises to the surface, and the casein sinks to the bottom if the fluid be allowed to stand. The peptone reaction comes out well.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The library of the College will be closed on Tuesday, Wednesday, Thursday, and Friday, the 4th, 5th, 6th, and 7th of January, and on Friday, Jan. 14th, for the purposes of the examinations of the Examining Board in England and the Primary and Pass Examination for the diploma of member of the College. We believe these will be the last occasions on which the library will be closed for examination purposes, as the new Examination Hall is expected to be ready by the end of March.

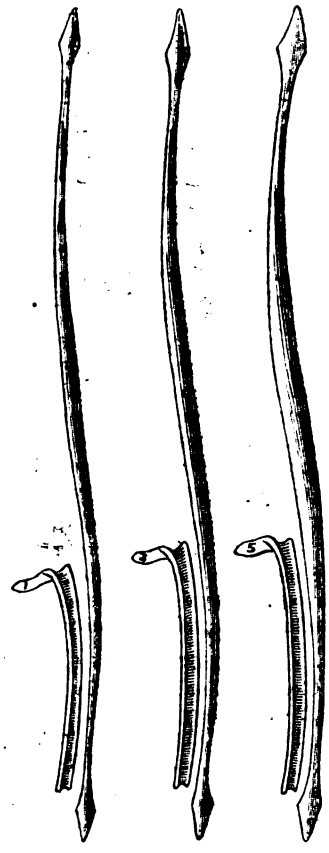
New Inventions.

A NEW STYLE FOR FACILITATING THE TREATMENT OF STRICTURE OF THE LACRYMAL DUCT.

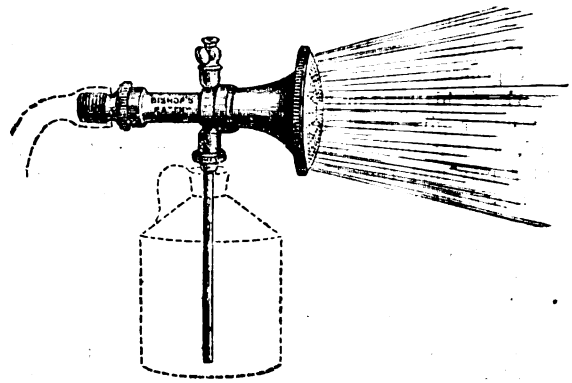


THE many difficulties in the way of satisfactorily treating obstinate cases of this apparently simple affection have induced me to devise the instruments which I have the honour of bringing before the notice of the profession. These instruments are grooved styles of various sizes, as shown in Fig. 1, are made of silver-gilt, and are each arranged to slide along Bowman's bulb-ended lacrymal probes. They are so constructed that the probe and its corresponding style will together pass through an opening which will not admit the next-sized probe. In performing the operation, as soon as the canaliculus has been slit up and a probe inserted, a style of corresponding number can be gently pushed along the probe through the stricture.

FIG. 1.

Showing grooved styles. Nos. 5 and 6 have been selected for the diagram.

FIG. 2.



Showing probes and grooved styles.

The probe is then withdrawn, leaving the style in position. After a few days' interval the probe may again be passed along the grooved style, and the small style replaced by a larger one. This process may be repeated until as large a style as may be wished has been inserted. This may then be left in the dilated stricture. In case of irritation produced by the presence of the style, it may be withdrawn and replaced in a similar manner as before when the irritation has subsided. The cases in which these grooved styles will be found most useful are: (1) Very tight or almost impermeable strictures. (2) Strictures complicated with fistulous openings and displacement of the natural passages. (3) Strictures in children or very nervous subjects. The advantages claimed by using these instruments are: (*a*) Greater facility of introduction. (*b*) It is more advantageous where rapid dilatation is required. (*c*) There is a more perfect system of drainage, of natural as well as of inflammatory secretions. In those cases in which I have had an opportunity of putting the instruments to a practical test the result has fully realised the expectation formed of them, and I venture to think that their use in dealing with almost intractable cases will be attended with much benefit.

FREDERIC DALE, M.D. Cantab., F.R.C.S. Eng.,
Surgeon to the Scarborough Hosp. and Disp.

BISHOP'S PATENT DISINFECTANT DISTRIBUTOR.

THE simple apparatus of which we give an illustration has recently been invented by Mr. Bishop, of the pharmaceutical department of Charing-cross Hospital. It appears to us to be as valuable as it is simple, and we have no doubt that it will be extensively employed. One of the chief difficulties in the use of all liquid disinfectants is the uniform and accurate dilution of the fluid selected. "Directions for use" are of course given on each bottle, but they are very irregularly followed, and injuriously large or absurdly small quantities are often added by those who have to do the actual work. With Mr. Bishop's disinfector mistakes can easily be made impossible, and the danger of neglect is reduced to a minimum. It will be seen from the drawing that an ordinary rose jet, capable of attachment to an india-

rubber hose or to the cock of the water-supply, is made to draw in by lateral suction a definite quantity of any liquid disinfectant. The lateral tube is provided with a small stopcock, by which the supply of disinfecting liquid is regulated. We have seen the apparatus tried with strong carbolic acid and with permanganate of potash, and can testify to the ease with which the proportion of disinfectant to water may be controlled and a perfect mixture effected. The apparatus can be set so that, for example, 1 in 40, 1 in 80, or 1 in 160 parts of the disinfectant can be introduced with the water without the possibility of variation by the operator. This is exactly what is wanted in public urinals, ships, stables, and many other places where frequent disinfection is required. By a simple modification the automatic disinfection of waterclosets can also be effected. The apparatus can be obtained of the inventor (47, Maygrove-road, Brondesbury).

MENTHOL INHALER.

CUSHMAN'S patent menthol inhaler has been submitted to us by Messrs. Christy and Co., 155, Fenchurch-street, E.C. It is of pocket size, and consists of a strong glass tube four inches long, with a tapering nozzle at one end, which can be introdnced into one nostril. The tube is filled in the central three-fourths by menthol crystals, and a free passage of air through these is possible by the aid of a spiral of metallic wire. Perforated corks and a kind of grate at either end of the crystals allow of ingress and egress of air without the falling-out of the menthol. Each end of the tube is fitted with corks to prevent evaporation of the menthol when the inhaler is not being used. The inhalation of air drawn through the menthol is said to prove of service in mitigating headache and lassitude resulting from excessive head-work and deficient exercise. Various neuralgiæ and nervous affections, hay fever, influenza, and catarrh may be relieved or cured by the inhalations.

ALCOHOLIC POISONING.—A child, aged five, died in Dublin last week from having swallowed a noggin of whisky administered by his father while intoxicated.

THE LANCET.

LONDON: SATURDAY, JANUARY 1, 1887.

It remains to prophesy without being able to ensure the fulfilment of the predictions made. The year 1887 is especially one in respect of which no observer having any considerable experience of the vicissitudes of politico-social life would willingly hazard a forecast. It may happen that the intentions of undoubtedly well-meaning, but possibly too sanguine, statesmen and administrators will not be carried into effect, and that, after all, the session of Parliament to be held in the year on which we are entering will not prove the most productive of beneficent and lasting results. It may chance that no measure for the reconstruction and amendment of the laws relating to lunatics will be brought under the consideration of the Legislature; or that if such a measure should be introduced it will either fall through for lack of time for its discussion, or be thrown out by one of the two Houses; besides which, it may prove to be either objectionable in itself or worthless. Whatever its fate, there are precedents for each and all of these destinies of a Lunacy Bill. It is probably fair to assume that, whatever party may be in office, and whether or not there be any exceptional parliamentary enterprise in the coming session, there will be this year a formulated scheme, of some sort, before the Houses for the development of local government; and it can scarcely be that a measure of this class will fail to raise issues, affecting the health of the community, which will demand the very serious attention of those who are engaged in the practice of medicine in its several departments. Without anticipating, it may be stated briefly that no proposal to alter the laws controlling the government of localities can be satisfactory unless it include arrangements for the more responsible and efficient administration of local affairs relating to health-preservation and the stamping out and prophylaxis of disease. We heartily wish it were reasonable to hope that the statesmanship of 1887 would rise to the dignity of that comprehensive and far-sighted view of our public needs which perceived the great and urgent necessity of a Ministry of Health—the logical outcome of a policy which once found expression in the phrase, *Sanitas sanitatum, omnia sanitas*. As regards medical reform, we cannot look upon what has been accomplished in this province in any light other than that of a provisional achievement. Sooner or later, and the sooner the better, there must be another step of progress towards a fuller development of the single-portal system. Granting everything that can be said for the claims of various interests and the so-called rights of the many licensing bodies, each and all of which give admittance to the Register, it must be affirmed that the real and permanent interests of the general community require that there shall be one statutory examination which all must pass who would practise the art of healing in these realms, and which shall be the portal to legal qualification. The acquisition of higher titles and distinctions in particular universities are doubtless to be encouraged, and the qualifications thus obtained may be held as honours; but it is unsafe in the interests of the public and the general health of the community to assume that what seems the greater attainment must necessarily include the lesser qualification for all-round practice; and it is therefore imperative that there should be one pass examination of a thoroughly practical character, which shall ensure a safe minimum of knowledge and capacity, and to which every member of the profession must submit himself, let his "superior" qualifications or special learning be what they may. It would be fortunate if it were possible to include a measure to establish this one-portal system in the legislative programme of 1887. Among the reforms which lie, to a large extent at least, within the province of the profession itself, is a sagacious concession to the conspicuously reasonable demand which has been urged on behalf of the great bulk of the medical students of the metropolis, for a degree in medicine attainable in London itself. It has been deemed undesirable that the University of London should lower the level of its high scientific standard to the needs of the average practitioner, and it is proposed that the Royal Colleges of Physicians and Surgeons should combine to constitute a Senatus Academicus conferring an average degree. This project has now been finally cast as a practical measure, and it remains only to obtain legal authority for the function. We trust that the steps taken with this view will be successful. It is manifestly unfair and unreasonable that the capital should be almost the only available city in this country wherein a "pass" degree in medicine cannot be fairly obtained. The exclusion of the Apothecaries' Society from the confederation of the Colleges for this enterprise is, we venture to think, an act unworthy of the Physicians and Surgeons on the one hand, and unjust to the Apothecaries' on the other. It should never be forgotten that the Apothecaries Society was the first body to protect the interests of the great mass of practitioners, and it has borne the burden and heat of the day's work since the passing of the Act by which "The Hall" was constituted.

IN the "Prefatory Address" which appeared in THE LANCET of Sept. 28th, 1833, while referring to the evidence afforded—by the rejection of a Medical Bill "because it did not go far enough,"—that the Legislature was at length beginning to recognise the claims of a previously neglected profession, the founder of this journal made the following reflection: "Thus we observe a chain of effects, all referable to one important cause—a feeling which is wholly indebted for its origin to the exertions of a FEARLESS MEDICAL PRESS." It was to sustain this character and to assert and defend the rights and privileges of the medical body as "a profession to which is entrusted the guardianship of the public health," while acting the part of a friendly censor and critic, and striving to break down all injurious monopolies and reform abuses, that THE LANCET was established. The idea of creating a thoroughly independent and free organ for the profession was the dominant purpose of Mr. WAKLEY'S mature life, and to render the attainment of his purpose the more certain, his desire was that the proprietorship of the journal should continue in his family

Digitized by Google

By the lamented death of Dr. J. G. WAKLEY, who, being joint proprietor with THOMAS WAKLEY, F.R.C.S., had also acted as Editor since his father's decease in 1862, the proprietorship devolves on THOMAS WAKLEY, F.R.C.S., who has now brought in his son, THOMAS WAKLEY, jun., L.R.C.P. Lond., and the editorial direction will from this time rest in their hands. As in the past, so in the future, THE LANCET will be conducted as the organ of the profession as a whole, and not of any association, society, company, party, or clique. That the distinctive position occupied by this journal is appreciated by the profession is apparent from the striking fact that, although in every instance subscribed for, or purchased, for its own sake purely, and not distributed as the organ of a special body, it has attained a steadily increasing circulation, and is now more largely read and quoted than any other medical journal in the world. To meet the requirements of a widening circle of readers, the capacity of the journal has been enlarged, so that it now contains more matter than occupied its pages seven years ago, to the extent of about 20 per cent. And this very considerable increase calls for further development, to meet which the journal will be permanently enlarged to ninety-six pages in the present and subsequent issues, thus affording augmented facilities for the publication of original papers and the communication of new and useful facts and opinions, to the advantage of the profession, and, indirectly, of the public. The several departments in which the work of the journal is cast will be extended and strengthened as opportunity offers, and with a view to its increased usefulness as a medium of medical news second editions will be issued whenever it seems desirable, as on the occasion of the recent election to the Medical Council. No pains will be spared to enhance the value of the periodical to its readers, while nothing will be allowed to impair its efficiency as a representative and leading organ of the great body of medical practitioners. It might be unseemly to say more, but this much needs to be said, at the commencement of a year on which THE LANCET enters under, to some extent, new auspices. The modifications which have been made, or are contemplated, will be apparent to our readers; but the purpose we cherish and are seeking to carry into effect is that which the founder of the journal conceived and so successfully compassed during his lifetime (and which the late Dr. WAKLEY still further developed); and it cannot be better expressed than in his own words—namely, to ensure "that, as far as it is possible for the cultivation of the science of medicine to alleviate human suffering, the agonies of our fellow-creatures shall be made to succumb to the power which the human mind is capable of exercising when fortified by a knowledge of that science." In a very special sense it is true of all that interests us as a profession, and which makes our function one of the highest in the service of humanity, that "knowledge is power." To extend this knowledge, and to develop and secure the free exercise of that power which is antagonistic to disease, relieving suffering and prolonging life, has been and must ever be the one worthy object for which a fearless medical press exists, and its promoters strive.

THE peculiar joint affection that complicates certain cases of tabes dorsalis has been a fruitful source of controversy, and its precise pathogeny can hardly yet be considered established. Professor CHARCOT, who first described it, compared it to other nutritive changes depending upon nerve lesion, and has always maintained its peculiar specific character. The debate at the Clinical Society two years ago served, however, to show that, at any rate in this country, this view was not universally held. It would seem almost as if there was a natural divergence of opinion, according to the point of view from which the subject was regarded. The neurologist takes his stand on the primary disorder of the spinal cord, and deems the articular and osseous changes to be essentially secondary; the surgeon thinks mainly of the joint disease, and sees no essential difference between its anatomical features and those of arthritis deformans. To him the connexion is little more than a coincidence; the cord changes are independent of any direct relation to the articular. The Society still awaits a report from a committee appointed on that occasion, but if rumour be true, the committee are unable to arrive at any definite conclusion. It may then be useful briefly to revert to the opinions upon the subject expressed by Professor VIRCHOW at a late meeting of the Berlin Medical Society, especially as his standpoint is strictly that of the pathologist who investigates the nature of a disease from the lesions that mark it. It must, however, be observed that the clinical cause of tabetic arthropathy is in itself different from the joint affections with which it is contrasted, mainly in the rapidity with which the extensive joint destruction is evolved, and the entire absence of any inflammatory phenomena, characters which, taken with others, all point, as Dr. ROTTER, who introduced the subject at this meeting, stated, to something special and peculiar to tabes.

Professor VIRCHOW began his remarks by holding that it was quite legitimate to compare this affection with arthritis deformans; a condition, however, which is by no means well defined. Thus, it may be a general or multiple affection, idiopathic in origin, or it may be purely local, limited, and traumatic; and, moreover, changes similar to those of rheumatoid arthritis occur in old-standing dislocations, and (rarely) in syphilis. Between arthritis deformans and arthropathia tabidorum (as Prof. VIRCHOW prefers to style it), no marked anatomical distinction is possible, and it is owing to the disease being described in all stages that stress has been laid by some on variations which do not actually exist. In tracing out the series of changes that eventuate in the characteristic destruction of the joint, Professor VIRCHOW stated that the earliest change is in the cartilages, then follow synovial changes, then capsular, and finally extracapsular; and throughout the whole process no distinctive inflammatory lesions may arise. It is a progressive tissue change, but so masked and altered by degenerative processes that, looking only to the final result, it might be attributed merely to mechanical friction, to 'wear and tear." (It is of interest to note here that Mr. ARBUTHNOT LANE contributes to the current volume of the Pathological Society's Transactions a paper in which he argues strongly in support of the view that mechanical causes alone may suffice to induce the joint-lesions characteristic of rheumatoid arthritis.) But the erosion and final entire destruction of the cartilages are preceded by a hyperplastic

Digitized by Google

process, which begins at various points of the surface layers, and it is after this stage (too early to be often noted) that the destruction takes place, through fatty degeneration of the proliferated cells. Similar hyperplasia occurs at the margins of the cartilage, and here ossification may ensue, the new-formed bone often extending on to the neck of the bone itself. Later on the head of the bone is laid bare and gradually wastes, and from ossification of the marrow the exposed end becomes dense and porcellaneous; whilst the synovial membrane becomes the seat of villous growths in which bony or cartilaginous nodules may form. Lastly, the ligamentous structures are destroyed or ossified, and the disorganised joint loses all its normal characters, save the osteophytic formations that surround it and the atrophic changes that have destroyed the extremities of the bones. Now in the tabetic joint the chain of events is precisely the same, but the processes are hastened, and evidently the result of more irritation. To illustrate this Professor VIRCHOW exhibited two specimens, in one of which only the early stage of cartilage lesion was present; in the other the internal changes were extreme, with a great amount of ossification outside the rest of the capsule. The reason for the more rapid destruction of the joint in tabes is, he thought, to be found *not* in any direct trophic disorder affecting the particular joint, but in the general loss of nutrition of the subject of this disease. Tabes, then, would be a predisposing cause to the arthropathy, but the arthropathy itself would depend on local influences, which in consequence of the deranged nutrition operate with increased severity. He was sceptical as to the alleged occurrence of arthropathy in the early stages of tabes having any connexion with the changes in the cord, and suggestively alluded to the influence of syphilis as being competent to initiate the articular lesions; just as it is also doubtless in many cases the cause of the spinal sclerosis. The opinion of so high an authority as Professor VIRCHOW on this subject is worth attention, and his statements may do something to clear the way to the adoption of more tangible views than at present prevail as to the nature not only of tabetic arthropathy but also of rheumatoid arthritis.

THERE are few more pressing matters than the medical succour of the sick poor. The questions which challenge attention in connexion with this subject are urgent, and of public not less than professional interest. We may be excused for looking at the matter from a point of view specially important to the practitioners of medicine, albeit we would not ignore the more popular aspects in which it is desirable that it should be regarded.

It must be freely admitted at the outset that the medical profession is not animated solely by sentiment and the impulse of benevolence, in lavishing its time and skill on the treatment of cases occurring among the indigent. We are not less humane than our fellow-men, but it would be absurd to lay claim to exclusively charitable motives. A field must be found for practice, if our students are to be trained in clinical work, and it is only by clinical labour in a large sphere that such experience as qualifies a physician or surgeon to offer advice to his colleagues can be acquired. The opportunities for the study of our art and the mastery of its principles as the case demands can only be secured by the organisation of an extensive system of hospital relief for the poor, and therefore it must be conceded that the interest of the medical profession, as a profession, in hospital work is *professional*. In saying this we do not abate one jot of our claim to be credited with a full share of the philanthropy which animates the mass of right-minded citizens, but it is inconsistent with that feeling of self-respect which has its foundation in honesty of view and purpose to lay claim to more than this.

Having said thus much by way of clearing the position, it may be asked why—seeing that professional enterprise in hospital charity is in the main a business undertaking—should we, of all other professional men, affect to recoil from the idea of business? It cannot be that there are no limits to this enterprise marked out by prudence and sound policy. In plain truth, there must clearly be a point beyond which it is selfish on the part of any one class of practitioners to push their ambitions and endeavours to the damage of their fellow-practitioners and the profession as a whole. Unless we are to assume that the great body of the medical profession is composed of men who labour solely for the love of science and humanity, and that they are not, in large measure at least, dependent upon the emoluments derived from professional business for their support and that of their families—propositions too ridiculous to be entertained,—it must be manifest that the extension of hospital charity further than the boundary line determined by the actual indigence of the subjects of relief is a direct injury to the profession. We cannot even admit that it is legitimate to afford facilities for the gratuitous supply of advice to the sick poor unless such advice is actually needed. There is a great deal of spurious sentiment about the glamour cast over this subject on platforms and in the reports of committees. No one for an instant doubts that it is proper to give medical succour to those who cannot otherwise procure it, nor is it questioned that all the successful treatment a case demands ought to be furnished in every instance of real need. The medical profession is fully prepared to make any sacrifice to these ends. What the great mass of practitioners are *not* prepared to do is to bolster up a system by which they are required to look on with amiable equanimity whilst a vast proportion of the classes who can pay, reasonably well, for advice and medicine are not simply supplied with both gratuitously, but persistently touted for by rival charities administered by injudiciously philanthropic committees. We are not in the least degree surprised, nor can we say that we are sorry, that this feeling has at length found expression, and that the body of practitioners are beginning to move in the matter.

Hospital charity, as regards both in and out-patients—though more particularly, perhaps, the latter,—is rapidly becoming an abuse. The aggregate of relief given, and boasted of, has reached a total which constitutes a very heavy drain on the resources of the profession as a whole. It would perhaps be under the mark to estimate that fully five-and-twenty per cent. of the relief given is not actually required. By this we mean that if it were impossible, or even a little less easy than it now is, to obtain gratuitous medical and surgical aid at the hospitals, probably one-fourth of the total number of persons

Digitized by Google

now relieved gratuitously would obtain assistance at the hands of the profession generally, and *pay for it*. It is not succour necessary to save life the hospitals are giving, but something to spare the pockets of persons who could, if they needs must, find the means of obtaining it by reasonable payment.

We offer no apology for speaking thus plainly on a subject of very immediate and widespread interest. It is time to cast aside traditional prejudices, and set the truth before our readers, and, through them, before the public. The medical profession is long-suffering, but it must sooner or later defend itself against the development of a policy which exaggerates self-sacrifice until it verges on the suicidal. We cannot hesitate to affirm that the amount of gratuitous relief afforded almost indiscriminately by medical charities has reached proportions which are not simply formidable but overwhelming, and the majority of practitioners will agree with us that this is rapidly becoming a cause of scandal. It is neither wise nor kindly on the part of the medical staffs of hospitals to shut their eyes, or affect to shut their eyes to the fact that they are inflicting a very serious and increasing injury on their fellows by assisting in the folly of pushing unnecessary charity beyond all due bounds.

WE are very pleased to be able, in this our first issue for a new year, to record the completion of the initiatory step towards the securing of degrees for medical students educated in London on the same terms as those which obtain in the great medical teaching centres in Scotland and the provinces. The Royal College of Physicians of London and the Royal College of Surgeons of England have now finally settled that it is "desirable and practicable to grant degrees in medicine and surgery to persons who have passed the conjoint examinations of the two Colleges"; also that "an application be made to the Crown by the two Colleges, acting conjointly, for power to confer degrees in medicine and surgery." The grievance of the average London medical student, that he is unable to obtain a degree under conditions similar to those which prevail elsewhere, is now definitely admitted, and the official authorities who determine his curriculum and period of study are pledged to its removal, if they can do so. A decisive step has been taken, and from this there can be no retreating. An application to the Crown for a Charter empowering the two Colleges, acting conjointly, to grant degrees, has been determined on. This conjoint action preserves the individual character of the two corporations respectively, and is only a necessary move forward in harmony with the spirit and the needs of the time. The Committee of Delegates appointed by the two Colleges will now have to consider upon what terms the degrees shall be granted, and these will have to be practically decided on when the application for powers is made. The principle is agreed to, but the working out of the details will require most grave and serious consideration, and must be settled speedily and without any waste of precious time. It will probably be dependent on the nature of the detailed scheme whether the opposition which is sure to be forthcoming will be successful or futile, and whether the application for powers will be supported earnestly and thoroughly by the teachers and the profession as well as by their leaders in the Colleges. No thought of an "inferior degree" can be entertained for a moment, and doubtless it was a fear lest some such result might be the outcome of the movement that caused the taking of a hostile vote to be insisted on by the very small minority at the College of Physicians on the 23rd ult. The degrees must be equal to the Scotch and provincial degrees, and when this equality is secured, no higher level is required or called for. The degrees must be "pass" degrees only. The Senate of the University of London has over and over again affirmed that all its degrees must be considered "honours" degrees, and it is from its determination to remain immovable at this standpoint that the present difficulty and grievance have arisen. The lowest preliminary examinations in Arts recognised by the General Medical Council are quite insufficient for a degree, and candidates for the distinction must be compelled to show a higher standard of general education. A revision of the present examinations for the qualifications of the combined Colleges is also necessary, so that some biological knowledge on the part of the intending graduate should be secured. The degrees of M.B. and B.S. might then be given on the existing professional examinations, and a decided tone would be added to the higher degree if some such suggestion as Sir WILLIAM GULL'S were adopted—that a further examination in *clinical* medicine and surgery be instituted for the M.D. and M.S. respectively. If the details of the scheme follow these lines, no one will be able to sneer at the degree as an "inferior" one, and much will be done towards raising the general and special education of the average London student. This is a reason for its existence which is too important to be overlooked.

Before leaving the subject, we must point out the great assistance to the movement, both in council and debate, which has been afforded by Sir WILLIAM JENNER and Mr. SAVORY, the Presidents of the two Colleges, and by Sir H. PITMAN, the Registrar of the College of Physicians. Dr. WILSON FOX and Mr. DURHAM led the movement by first bringing it before the Colleges for their official consideration, and it has been most generously supported, among others, by Sir ANDREW CLARK, Drs. BRISTOWE and WILKS, by Sir JOSEPH LISTER and Messrs. MARSHALL and MACNAMARA. Sir WILLIAM GULL and Drs. LATHAM and PRIESTLEY, by an acknowledgment during the recent discussion of their conversion to the necessity of some such scheme, have rendered it a conspicuous service. We must also refer to the late Dr. MOXON, who at once saw the justice of the agitation in its favour, and by his articles in our columns and his speeches gave it an impetus such as only his characteristic fervour and singleness of purpose could impart. His wise counsels in directing and assisting the progress of the movement will be much missed.

IT was decided at a meeting on Dec. 27th last of the governors of Addenbrooke's Hospital, Cambridge, that a dental department with two dental officers should be instituted, the cost not to exceed £50.

THE Queen has been pleased, on the recommendation of the Secretary for Scotland, to appoint John Theodore Cash, M.D., Professor of Materia Medica in the University of Aberdeen, in the room of Dr. Dyce Davidson, deceased.

Annotations.

"Ne quid nimis."

WOOLWICH AND SANDHURST.

THE information given in the reports of the Board of Visitors respecting the health of the cadets at the Royal Military Academy, Woolwich, and the Royal Military College, Sandhurst, is of the most meagre character. Prior to 1885, a return, by the medical officer, of the cases of sickness occurring among the cadets was always appended to the report of the Visitors, and occasionally remarks by the medical officers were incorporated in it. Last year the hospital return was omitted for the first time, and it has not been restored in the reports just issued for 1886. We are disposed to attribute the omission to the remarks, not devoid of a complimentary nature, which we have felt it our duty to make upon the health-condition of the two establishments, and the necessity for a careful inquiry on the part of the military authorities into the causes of the abnormal amount of sickness which the returns showed to prevail, especially at Woolwich. In this view we are confirmed by a remark in the report of the Visitors to Woolwich in 1885: "It is not possible to draw a comparison between the cadets of the Royal Military Academy and those of the Royal Military College, as the position and the surroundings of Woolwich will in no respect compare with those of Sandhurst." But surely, when there is such a difference in the cases of sickness as was shown by the medical returns in 1884, when Woolwich had 1227 cases per 1000 against 639 at Sandhurst (see THE LANCET, Dec. 20th, 1884), it is only a fair presumption that some other causes of sickness are in operation besides "the position and surroundings" of Woolwich. We cannot but think that it would be a much more judicious course to furnish correct information respecting the health of the cadets, than to give grounds for the inference that it is so unsatisfactory as to require the suppression of the established returns respecting it. In the reports for 1886 the only definite information respecting the health of the Woolwich cadets is, "The medical report shows a daily average of 2·90 on an average of 319 gentlemen cadets"; and of Sandhurst, that "the medical officer reported their health to have been good during the past year, that there had been no cases of serious illness, and that the average daily sick was 3·78 on an average strength of 304 cadets." These figures show the constantly sick at Woolwich to have been in the proportion of 13·2, and at Sandhurst of 12·4 per 1000, a sufficiently high ratio, from which it is impossible, however, to draw any conclusions in the absence of all information as to the diseases by which it was caused. The want of this is the more to be regretted as the conditions in which the cadets are placed at Sandhurst, as regards their rooms and the hospital accommodation, appear to be much more satisfactory than at Woolwich. We trust that in future reports of the Visitors the returns of the medical officers may again be given, as formerly, for the satisfaction of the parents and friends of the cadets. We were much pleased to see that at the annual inspection at Sandhurst the Duke of Cambridge directed that, as desired the medical officer should receive [illegible] commendation for the skilful manner in which he had stamped out what threatened to be an epidemic of [illegible] some little time since." It was a well-earned [illegible] to Brigade-Surgeon Clarke, the able and zealous [illegible] of the College.

INTER-COLONIAL MEDICAL CONGRESS.

THE South Australian Branch of the British Medical Association recently appointed a committee to take steps in the initiation of an Inter-Colonial Medical Congress, to be held at Adelaide this year during the Jubilee Exhibition period. The cordial responses received from South Australia and the adjoining colonies to the preliminary announcement of this committee warrant, we understand, the prosecution of the scheme with every anticipation of good results. It has been decided to hold the Congress in August and September, during the University vacation, the meeting to last not more than six days. The promoters of the Congress, we are glad to learn, wish the meetings to be under the direct guidance of the whole body of the profession in the colony, as it is most desirable that the Congress shall be of a thoroughly representative character. It is anticipated that the attendance from the sister colonies will be large and influential. We congratulate our colonial brethren upon their enterprise and courage in organising a rival to the great meeting of the profession which is to be held about the same time in the United States, and sincerely trust that their anticipations of success in their undertaking may be realised: though they cannot command success, they may at least deserve it.

THE REGISTER OF MEDICAL STUDENTS.

THE third report by the Statistical Committee of the General Medical Council has just appeared. It contains a summary of statistics regarding medical students registered as commencing their curriculum in the quinquennium of 1871-75. The investigation of the committee, to the success of whose labours, it is scarcely necessary to say, the aid of the registrar, Mr. W. J. C. Miller, has been indispensable, has included the tracing of 6403 registered students, of whom 4472 were found to have gained a place in the Medical Register. The committee propose to elaborate their work by constructing a census of the profession at two selected annual periods, the years chosen for this purpose being 1881 and 1886. "In such quinquennial censuses," remarks Mr. Marshall (chairman of the committee), "many most interesting points will be cleared up, such as the strength of the profession, its distribution amongst the population of town and country, its fluctuations, its migrations, and many other details relating to titles, qualifications, age, mortality, and so forth. The construction of these censuses will be a comparatively easy task, as compared with that already accomplished. It will be undertaken by the same diligent and accomplished agents as we have hitherto had the advantage of engaging, and care will be taken to make the basis and outcome of the inquiry as sound and accurate as possible."

SMALL-POX INOCULATION.

IN a lecture recently delivered at St. Mary's Hospital Mr. Shirley Murphy adduced some evidence to show that there was a probability that the virus of small-pox obtained from the initial vesicle produced by inoculation of small-pox differed in its action from that obtained from the general eruption; and he expressed the opinion that it was probable the different results attending the operation of inoculation by various operators might be dependent upon the use of virus procured from the one or the other source. Thus of 182 inoculations performed in the years 1721 and 1722, three persons died, or nearly one in sixty; and in Dublin, in 1723, of twenty-three persons inoculated, three died. The not infrequent death from inoculated small-pox led at first to much opposition to this method of protection against natural small-pox, but later it was found that inoculation could be performed without risk. In an account given by Sir George Baker of the

Digitized by Google

extraordinary success attending the inoculations of Daniel Sutton, of Ingatestone, in Essex, who in three years inoculated some 20,000 persons without bad result, he attributed this success to the fact that Sutton allowed his patients to enjoy fresh air during their illness; while Dr. Glass of Glasgow believed that Sutton's treatment in encouraging perspiration was responsible for their recovery. It is clear that Sutton professed to have a secret in his treatment, although this secret is only mentioned in relation to the composition of certain medicine; but Sir George Baker, curiously enough, observed that "What is extremely remarkable, he (Sutton) frequently inoculates people with the moisture taken from the arm before the eruption of small-pox"; and Dr. Chandler, who also witnessed Sutton's work, referred the chief benefit of his plan to the infecting humour being taken in a crude state "before it has been ultimately variolated by the succeeding fever." Baron Dimsdale, who took much interest in Sutton's proceedings, and subsequently himself practised inoculation, closely imitated his method, and was very successful in his results. If, as Mr. Murphy pointed out, the virus of the initial vesicle differs in any respect from that of the general eruption, some difference may also be found in the ease with which the bovine animal is inoculated with the one and the other virus. Certainly this point deserves further investigation.

M. VERNEUIL AT BRUSSELS.

M. VERNEUIL has been paying a short visit to Brussels, where, in return for the hospitality of his Belgian *confrères*, he treated them to several interesting and instructive speeches and lectures. They seem to have kept him somewhat hard at work, for on the Saturday (Nov. 27th) he was present at a meeting of the Royal Academy of Medicine, where he gave an important address on Vertebral Disease, in which he insisted on the importance of prolonged rest and immobility of the vertebral column, mentioning that when absolutely necessary he let out pus, injecting subsequently a 5 per cent. solution of iodoform in ether. On the Sunday he gave a lecture on Tuberculosis at the Hospital St. Jean, and on the Monday visited the surgical and children's wards in the Hospital St. Pierre, where he gave clinical lectures on cases of Comminuted Fracture, Abdominal Tumours, and Hip Disease which were shown him, delighting his audience with his diagnostic acumen and his happy phraseology.

"COUP DE VENT."

OUR neighbours, the French, have the advantage of a language which is both epigrammatic and comprehensive, and is capable also of giving expression to an idea with the greatest scientific exactness. It has therefore been acknowledged to be the best language for European diplomacy, as well as that of polite intercourse at nearly every Court of Europe. The "coup d'œil," the "coup d'état," and the "coup de vent" of the French have no such expressive equivalents in any other European language. The sudden changes in the weather of the past few weeks, from days of bright sunshine to murky nights, from days of damp and fog to sharp frost with dry and bracing air, from wind rising to a hurricane to atmospheric stagnation, with scarcely sufficient movement to divert the upward current of the smoke from our chimneys, and these alternations varied from time to time by a keen piercing north or north-east wind, have brought home to many of us the chilling influence of a "coup de vent." A very much lower temperature can be borne when the atmosphere is at rest than when it is in active motion. In Captain Parry's account of his voyage to the North Pole it is stated that the crew suffered less when the thermometer was 55° below zero—i.e., 87° of frost—in a still atmosphere, than when the thermometer was as high as zero, with a keen wind blowing. Stagnant dry air is a very bad conductor of heat: thus the film of the atmosphere immediately surrounding the body parts very slowly with the warmth which is abstracted from the body; it becomes, indeed, an intermediate temperate coating between the colder atmosphere and warmer body; but when air is in motion this intermediate protecting film is removed, and a chilling atmosphere is repeatedly brought nearer the surface of the warmer body, with a risk of producing what the French graphically call a "coup de vent."

THE METROPOLITAN PUBLIC GARDENS ASSOCIATION.

THE fourth annual report of the Metropolitan Public Gardens Association has just been published, and is a highly satisfactory one in every respect. The Association, which works in conjunction with the National Health Society, was formed, as most of our readers are doubtless aware, for the purpose of supplying one of the most pressing wants of the poorer districts within the metropolitan area—namely, to provide breathing and resting places for the old, and playgrounds for the young, in the midst of densely populated localities. The following is a brief summary of the work accomplished during the past year:—Seven recreation-grounds have been laid out and opened to the public; trees have been planted in one garden and one thoroughfare; seats have been placed in ten public gardens; grants of money have been made to five public gymnasia; two commons have been improved; and assistance has been given in the formation of a swimming-bath and a recreation club. The income has been raised from £7283 in 1885 to £10,917 in 1886, and the membership has increased to 448. London is year by year becoming more and more populated and extended. The ever-widening girdle of bricks and mortar, the ever-increasing height of dwellings and warehouses, the tendency that there is for the current of human life from all directions to flow towards the metropolis as a centre, can have but one possible effect, and that is to render London less and less a place where the bodily functions can have full and natural play, where bone and muscle in the young may be developed, and where constitutions are able to ward off disease and postpone decay. The Association, by securing open spaces, is adopting the best method to meet this threatened evil, and those who have the health and welfare of the toilers in this modern Babylon at heart will be unable to resist Lord Brabazon's appeal for renewed, increased, and fresh donations and subscriptions to the funds of this most useful and deserving Association.

HOSPITAL REQUIREMENTS.

SIR RUTHERFORD ALCOCK writes a long letter to *The Times* on the present serious deficiency in hospital support, the chief burden of which is to suggest the urgency of inquiry into the whole subject by a Royal Commission. The medical profession has had very recent experience of the limited powers of a Royal Commission. Such a Commission, composed of most influential men, took a great deal of trouble and a great deal of evidence, and came, by a majority, to certain recommendations for legislation on medical matters. But the legislation which followed came grievously short of the recommendations. The best portion of Sir Rutherford's letter is that in which he elucidates the grievous deficiency in the incomes of all the hospitals. He thinks the urgency of the case is not realised by the public. We hope his letter will help the public to do so. If not by a Royal Commission or otherwise, the facts must be faced and the remedies pointed out.

ADELAIDE UNIVERSITY AND MEDICAL EDUCATION.

THE University of Adelaide has recently instituted a medical school, not without some opposition, it being contended that the Universities of Melbourne and Sydney are amply sufficient to supply medical graduates to the colony, which is already becoming as much overstocked by the profession as is the mother country. The scheme, however, has been warmly taken up, and subscriptions to the amount of £16,000 were announced at the meeting of the Senate, which decided to make this new departure. Such private endowments will now be supplemented by grants of public money. For our own part, we do not see why South Australia should decline to further the cause of higher medical education, or why its resources are not adequate to supply a properly equipped medical school. The question of overstocking the profession is one which can always be met by the stringency of the tests imposed on those who seek to enter it.

THE CROWN SEAT FOR IRELAND IN THE MEDICAL COUNCIL.

ALL who knew Dr. Lyons will deeply regret his death. He was one of those genial Irishmen who could hold a different creed without bating any of his respect for those from whom he differed. It would have been better for Ireland if more of her representatives had had more of his nature. The Government will have to fill his place in the Medical Council. Many provincial Irishmen are hoping that advantage may be taken of the vacancy to give the Irish practitioners in the Provinces a representation which even Direct Representation has not disposed them to secure. We should be glad to see the Government take this liberal view of their opportunity. We must admit that the practitioners of Ireland, by failing to elect one of their own rank when they had the chance, have given occasion for the remark that they prefer Dublin consultants to provincial fellow-practitioners. But the Government should make allowance for the enormous vantage-ground enjoyed by the Dublin magnates in an election; and it would act generously in supplying the conspicuous defect of the Medical Council—a typical representative of the general body of practitioners in Ireland.

TOOTH POWDERS.

PROPHYLACTIC medicine is of greater value to the public than curative, although they are slow to give it its due; hence the subject of tooth powders may be of some interest. The necessity of keeping the teeth clean, with a view to the prevention of future trouble, is overlooked by too many, even in the higher classes, sometimes from carelessness, sometimes from ignorance. Now, cannot the medical attendant do a great deal to combat this state of things? The dental surgeon is often asked, "How soon should the first tooth-brush be used?" "As soon as there are teeth to use it upon" should be the reply. An ideal tooth-powder should be alkaline, since acids dissolve the tooth substance; finely pulverised, that it may not mechanically abrade; antiseptic, to prevent decomposition of food lodged between the teeth, and perhaps to destroy the microbes which are always found choking the tubules of carious dentine; it should contain nothing irritating to the gums; and, lastly, it should be pleasant to the taste, or it will not be used. Fluid dentifrices do not, as a rule, clean the teeth effectually, unless they contain some ingredient which acts upon the enamel itself; and those preparations which are eulogised as making teeth white or preventing deposit of tartar, should be avoided. Charcoal was at one time a very popular form of dentifrice, and is even now largely used, but from the amount of silica it contains it will rapidly wear away teeth that are not of exceptional hardness; and, moreover, the gums in some instances become tattooed in a curious manner from absorption of minute particles. Pumice-powder, again, is too gritty; and camphorated chalk is said to make the gums spongy. Precipitated chalk forms the best basis for a tooth powder, to the base of which may be added pulv. saponis and ol. eucalypt., a drachm of each; and, if there is no objection to the taste, half a drachm of carbolic acid.

REFORM OF THE SCOTTISH UNIVERSITIES.

A MOVEMENT very similar to that of the Members of the Royal College of Surgeons in England for representation in the Council now obtains in the Scottish universities. The members of the University Council, consisting chiefly of the graduates, desire to have a larger representation than they have at present in the University Court. They protest that this desire is not based on any selfish or revolutionary purpose, but on a conviction that such representation will give an impetus to important changes in the regulations and administration of the University, tending to raise their standards, especially in Arts. It is not proposed to interfere with the vested interests of existing professors, but to endeavour to give the University Court more power over the curriculum and the recognition of extra-mural teaching. Lord Wemyss has accepted the office of President of the Association of the Council of the University of Edinburgh, and from the chair of the Association has expressed his agreement with the objects of the Association, and several of the professors have already done the same. A similar Association exists in Glasgow, and Professor Edward Caird has given it valuable assistance. The Scottish universities are being, and will be, subjected to much criticism, the best answer to which will be the readiness of their professors to accept any reasonable improvements in their constitution, even if involving some control of the powers of the Senatus.

HOME FOR LOST DOGS.

EVEN those who objected to the muzzling of dogs will not complain of the translation of ownerless animals from the streets to comfortable quarters. The temporary Home for Lost and Starving Dogs, Battersea, has received into its kennels over 40,000 animals in the course of the year and ten days during which the muzzling order has been in force. This institution is not responsible for the seizure of dogs; it acts as a trustee of public property. We are sorry to learn that there is a debt of some £1500, the result chiefly of the great demand on the Home during the period of the police edict. The committee appeal for subscriptions to meet their present difficulty. Assuredly the object to which the money has been applied was in the highest degree humane; the results, both for human beings and dogs, have been entirely beneficial. There can be little doubt that the purse of the charitable will be opened with the usual liberality of the British heart.

BULLET WOUND OF ABDOMEN.

EARLY on the morning of Dec. 25th a man aged twenty-three was admitted into St. Thomas's Hospital, under the care of Mr. Mackellar, suffering from a bullet wound of the abdomen inflicted about two hours previously. The bullet, which had been fired from a revolver at a distance of about 18 ft. above and to the left of the patient, had made a small opening 2 in. above and 1 in. to the inner side of the left anterior superior spine of the ilium. There was no evidence of wound of the bowel, and there was comparatively a small amount of shock; but on the following day sym-

Digitized by Google

ptoms of peritonitis developed, and the abdomen was explored. Mr. Mackellar found two perforations with bruised edges in the lower part of the sigmoid flexure, from which there had been an escape of contents of the bowel; these openings were secured by ligature, the effused blood and other fluid carefully washed out, and the wound closed and drained. The patient rallied from the operation, but died a few hours later. At the post-mortem examination the bullet was found lodged in the right side between the bladder and rectum. No other portion of bowel had been wounded. The openings in the bowel were not sutured on account of the collapsed condition of the patient, the distance of the wounds from the surface, and the fixation of the gut, which prevented its being brought out of the abdomen. For similar reasons the question of excision of the wounded part was dismissed. The man was acting as a "wait" at the time of receipt of the wound, and his sad death ought to act as a warning to those who are in possession of fire-arms and careless in their use.

LIFEBOAT CREWS AND LIFE INSURANCE.

WHILE the recent terrible disaster to the Southport and St. Ann's lifeboats still remains fresh in public sympathy, it may be well again to refer to the subject of life insurance as a provision against the death of the bread-winner for the maintenance of his widow and orphans. By this sad misadventure twenty-seven valuable lives have been lost, and what makes it even more deplorable is that the men to save whose lives they lost their own were all rescued before the latter started on their mission of mercy. Among other lessons to be learned from this disaster, we may trust that it will not in future be permitted that a man suffering from well-advanced phthisis shall be entrusted with the responsible duties of coxswain—a position requiring the soundest mind in the soundest body. We may also expect further improvements in the construction of lifeboats, and better means of communication between lifeboat stations within view of the same points of danger, though out of sight of each other. But when all this has been done, and the lifeboat service has been made as perfect as possible in human hands, we must still expect that accidents and misadventures will happen in the future. It is very gratifying that a sum has been raised, not only sufficient to provide amply for all the bereaved families, but even to leave a surplus, which a contemporary suggests should form a nucleus of a fund for the relief of sufferers from future similar disasters. Would it not be better, however, to apply any such surplus in aiding lifeboat men to effect an insurance on their lives against all risks, or, if this be not practicable, specially against the risk to which they are necessarily exposed? We would earnestly commend to the Royal National Lifeboat Institution the adoption or modification of the plan carried out for many years by the Commissioners of Northern Lighthouses. Each lighthouse-keeper is insured for £100 in the Edinburgh Life Assurance Company. He must be an "insurable life" before he can be admitted into the service, and from his wages there is an annual deduction of £3 to pay the premium. In the event of his death, the principal sum is given as he may by will direct, or, if he die intestate, to his next of kin. At present the rate of premium for lifeboat men is no doubt high; but it may also be suggested to insurance offices whether it would not be to their advantage to offer facilities for such insurance. Should this suggestion be carried out and become as national as the lifeboat itself, great benefits would accrue. The men could not be braver, but they would go on their errands of mercy with lighter hearts, knowing that those dependent on them for their bread would be amply provided for. We cannot expect to see often such munificence as has been shown in the recent case; but by a system—partly compulsory, partly voluntary—every lifeboat man may provide for his wife and children without leaving them to the charity of the public. Nothing can be more reasonable than that the men in the service shall be insurable lives, and not only so, but insured as well.

HOSPITAL SATURDAY FUND.

THE delegates of the Hospital Saturday Fund for 1886 have seen their way to distribute £9750 out of about £11,000 realised up to a few days ago. The institutions to be benefited are seventy-five hospitals, thirty-nine dispensaries, and eighteen convalescent homes. The Board reserve 5 per cent. of the sum distributed for surgical appliances and other purposes. The chief awards to hospitals are:—Brompton Consumption, £589; London, £588; Victoria Park Chest Hospital, £288; Middlesex, £276 3*s.* 6*d.*; St. George's, £267 8*s.* 10*d.*; St. Mary's, £224 17*s.* 1*d.*; Metropolitan Convalescent Home, £211 0*s.* 5*d.*; Westminster, £208 0*s.* 1*d.*; King's College, £175 13*s.* 8*d.*; Royal London Ophthalmic, £174 2*s.* 7*d.*; North London, £176 12*s.* 1*d.*; Charing-cross, £162 11*s.* 1*d.*; University College, £204 8*s.* 8*d.*; Royal Free, £168 5*s.* 8*d.*; Hospital for Sick Children, £129 0*s.* 2*d.*; German, £115 19*s.* 10*d.*; Royal National, £108 4*s.* 10*d.*; City-road (Chest), £96 1*s.* 9*d.*; North-West London, £81 1*s.* 10*d.*; St. John's, £82 7*s.* 6*d.*; Royal Orthopædic, £89 0*s.* 8*d.* The great efforts of the Board to increase this Fund must be recognised; but it is disappointing to notice that they have not been more successful. The sums distributed do not exceed those of last year by more than £250. A sum of under £10,000 is altogether disproportionate to the ability of the working classes of the metropolis and to their obligation to the hospitals, which exist chiefly for them. A committee has been appointed to take the necessary steps for registering this Fund under the Friendly Societies Act. It is thought—though there is some difference of opinion on this subject—that some advantages will be gained by this, especially in acquiring greater facilities for dealing with occasional defaulters. But what is seriously wanted is a better method of organisation to gather weekly and regular subscriptions to the Fund. The present condition of the hospitals ought to make the time favourable for such action.

THE MEAT-SUPPLY OF MARSEILLES.

AMONG many other causes that contribute towards the exceptional insalubrity of Marseilles must be noted the fraudulent sale of meat unfit for human consumption. This is a grievance which affects not only the inhabitants, but also the crews and passengers of the ships, many of them English ships, that take provisions on board at Marseilles. It appears that in the district of Aveyron, and notably at Saint Afrique, the principal industry is the making of the celebrated Roquefort cheese. For this purpose the sheep as well as the cows are valuable principally on account of their milk. It is to the interest of owners to kill both calves and lambs before the flesh is sufficiently formed to constitute wholesome food. But a calf will consume an amount of milk which, in the Aveyron district, is equal to three francs a day, while augmenting in meat value at the rate of only one franc per day. Thus a calf, which should be kept at least thirty days, would cost ninety francs, and yield an increased value of only thirty francs. With respect to lambs, the loss is in the same proportion. It has therefore been the practice to kill lambs and calves at once, and import the meat direct into Marseilles. After the ravages made by the cholera the Mayor decided to issue a special decree against this practice. Henceforth the head must not be detached from the carcase, so that the presence of the teeth may testify to the age of the lamb or calf. But the above was not the only grievance. A bullock brought into Marseilles

Digitized by Google

and killed at the municipal slaughter-house paid, in all, dues to the amount of thirty-two francs. If the same bullock were killed outside the town and the meat imported, the dues to be paid would amount to no less than a hundred francs. Yet, in spite of this prohibitory tariff, a great quantity of dead meat was brought into Marseilles. The fact is, the meat came from animals that had been killed while ill, or that had died before they could be killed. Taught by the epidemics the necessity of attending to such matters, the Mayor has also decreed that beef, mutton, and pork can only be brought into the town if the owner has first secured the certificate of a veterinary surgeon who shall have seen the animals before they were slaughtered. These new regulations have not long been in operation, and it is too soon to speak of the effect produced. Few persons, however, will be found to cavil at their severity; and, in this respect at least, we can venture to congratulate the local authorities. Unscrupulous meat merchants will find, we trust, their trade destroyed, and the municipality has done well to protect the population and strangers who visit the port from their nefarious practices.

REPORTED CURE FOR LEPROSY.

UNDER this heading the *St. James's Gazette* of Dec. 17th quotes a portion of a letter from Father Damian, of the Molokai Leper Settlement, to a German publication, in which he shortly refers to and extols the wonderful effects of a treatment carried out at the Kakaako Leper Hospital by by Dr. M. Goto of Japan, who was invited over by the king. The treatment referred to is similar to that long carried out by Dr. S. Goto, of the Kihai Hospital, Tokio, Japan. It is hygienic, dietetic, and medical. Strong patients are bathed thrice daily, and weaker ones twice daily, in warm fresh water at 90° to 100° F., into which has been placed an infusion of a few ounces of Hichiyou bark (*Æsculus turbinata*), together with certain proportions of Taifuushi, sulphur, and other ingredients. The patients are fed generously, but not excessively, thrice daily, on rice, milk, beef, mutton, chicken, eggs, good strong broth, boiled taro, vegetables, and fruit; but sour poi and also raw fish, when used with the usual native condiments, are forbidden. The medical treatment "varies according to the condition of the patient and the stage and character of the disease." The two chief medicines used are, in all cases, Seiketsu-ren as pills and in large doses (? the bark of the Hoang-nan tree with realgar and alum), and yoku-yaku for baths. Dr. Goto also employs tincture of the perchloride of iron, sulphate of quinine, iodide of potassium, vegetable tonics and bitters, and the carbonate of soda and potassium, especially the alkaline salts. Under this treatment he reports, under date of April 20th, 1886, five cases as "almost cured," nineteen as "improving," and seventeen as "relieved."

THE VACCINATION OF THE AUSTRO-HUNGARIAN ARMY.

STRUCK by the wonderful fact that in the German army the compulsory vaccination had reduced the mortality from small-pox to *nil*, the Crown Prince Rudolph of Austria had been led to urge a similar precaution for the Austro-Hungarian army, and within the last few months, the *Evening Standard* observes, every soldier has been compulsorily vaccinated. The result is that whereas in Pesth a small-pox epidemic of great severity has been raging among the civil population (who are under no compulsion), there has not been a single case among the numerous troops of the garrison at Pesth. Of course all this will be explained away by our anti-vaccination friends, and the many who have died of small-pox will be regarded as better off than those who have been saved by vaccination. But the majority of people will not go wrong over such plain facts.

THE NEW REICHSTAG BUILDING AT BERLIN.

AN account of the proposed ventilation of the new Reichstag at Berlin has recently been published by Mr. W. H. Tyler, who gives an interesting description of the efforts that are being made to ensure the ventilation of the Houses of Parliament being as perfect as possible. The Grand Hall is to be ventilated by air admitted through the roof and drawn out through the floor, the air being drawn from a height of 250 ft. to ensure its purity. It will be first conveyed into a large chamber, where it will be prepared for admission into the hall. The preparation will consist of exposing it in winter to hot pipes, a surface of 43,000 square feet being required for this purpose. The same pipes in summer will contain a liquid at nearly freezing-point, so that the temperature of the hall cannot during this season of the year become unduly high. Here also it will be dried or moistened as occasion may require, and by a simple arrangement of valves the necessary quantity will be admitted. The hall is to contain nearly 1000 persons, each of whom is to be provided with 1420 cubic feet of air per hour. When the House is sitting, the air will be constantly examined by four assistants, who will report on the thermometer, hygrometer, and anemometer indications, and thus enable the engineer to modify it whenever this is required. It is thus expected that the condition of the atmosphere of the houses will be maintained in proper condition.

PENURIOUS TREATMENT OF MEDICAL OFFICERS.

WE have frequently had occasion to refer to the paltry remuneration which is offered for medical services by many municipal and parochial bodies. At a recent meeting of the Darlington Town Council a fact was incidentally mentioned which affords a fresh example of this short-sighted economy. It appears that the three medical officers who attend the poor of this considerable town, numbering about 13,000, and who with curious assurance are required to supply medicines and appliances, receive each per annum for these attentions the utterly insignificant sum of £35. With every allowance made for hard times and for work among the poor which may be done by medical men in independent practice, the sum above mentioned is, we repeat, unjustifiably small in comparison with the duties exacted in return.

NEW FOREIGN MEDICAL JOURNALS.

A NEW French weekly medical journal commences with the new year. Its object is to assert the importance of provincial medical science and to assist in the decentralisation of French medicine, which it is considered is concentrated too much at Paris. The title is *La Province Médicale*, and it is published at Lyons.

The appearance is announced in Vienna of two new medical journals—*Klinische Zeit- und Streitfragen*, edited by Professor Schnitzler; and a weekly entitled *Internationale klinische Rundschau*, edited by Drs. Bela Weiss and A. Schnitzler.

A SURGEON FINED FOR CERTIFICATE OF STILL-BIRTH.

THE writing of certificates is one of the chief ways in which medical men come into contact with public offices and public law. It is a duty which they cannot discharge too carefully. We regret to see that a medical practitioner has been fined £5 and costs for signing a certificate of still-birth for a baby that had lived a few hours. The mother was attended in her confinement by a midwife, though for phthisis, of which she died in the evening, she had been seen before and after her labour by the medical man. The

Digitized by Google

child lived a few hours. Statements varied as to whether this had been made clear to the signer of the certificate. But the magistrates imposed the above fine. It is a great temptation to save poor people all the paraphernalia and expense of a funeral for a child that can scarcely be said to have lived. But it would have been better to have left the midwife to state the facts, and in any case the utmost care to be accurate is necessary.

THE CARRIAGE TAX.

THE movement to repeal, or at least modify, the tax on carriages is one that deserves success, if it were only for the pertinacity with which it has been, and still is, carried on in the face of unaccountable neglect and opposition. A great mistake is made by those who think this is a "rich man's question." The profession of medicine is in this way undoubtedly unduly taxed, but it is the coachbuilders' class that suffers most, and the tax is a burden on industry. It ought to be abolished, and the magnitude of the revenue derivable from the tax is not so stupendous as to be overwhelming to any spirited Chancellor of the Exchequer.

THE ACCURACY OF THE NEW MEDICAL REGISTER.

THE Registrar of the Medical Council is very anxious to secure the greatest possible accuracy in the new volume of the Medical Register. This can only be attained by the co-operation of the profession, and especially of all those who have changed their addresses or added to their titles. If such gentlemen will immediately intimate such changes they will be duly registered; otherwise inaccuracies will remain which not only discredit the Register, but may disqualify practitioners.

THE PROGRESS OF CHOLERA.

IT is stated that there has been no recurrence of cholera in the neighbourhood of Tirnova since the first report, when eight deaths occurred. The sanitary authorities are, however, still maintaining a quarantine round the infected locality; and since the Bulgarian authorities decline to admit that any cholera has occurred within their principality, Roumania has placed Bulgaria in quarantine.

CHONDROMA OF THE LIP.

IN the Transactions of the American Dermatological Association for 1886 Dr. A. R. Robinson reports a very rare case of chondroma of the right side of the upper lip of a man thirty-six years of age. This affection has been described by Pagot under the term "labial glandular tumours."

OVERHEAD TELEGRAPH AND TELEPHONE WIRES.

THE recent heavy snowstorm has emphasised the lesson of warning as regards overhead wires. Many have fallen, and great damage has been done; but probably some considerable loss of life will be required to bring the facts clearly before the Legislature and to rouse public indignation to the boiling point.

FOREIGN UNIVERSITY INTELLIGENCE.

Bern.—Dr. Demme has been appointed Professor in Ordinary of Pharmacology and Children's Diseases.

Bologna. — This University will celebrate its seven hundredth anniversary in the Spring.

Bonn.—Dr. Franz v. Leydig, Professor of Comparative Anatomy and Zoology, will retire in April.

Freiburg.—Dr. Baumgärtner, formerly Professor of Pathology and Director of the Medical Clinic, died at Baden-Baden on Dec. 11th.

St. Petersburg. — It is now announced that Professor Nasiloff is to take charge temporarily of the surgical clinic—not Dr. Beltsoff, as originally stated. The report that Professor E. Bergmann of Berlin had declined an invitation to St. Petersburg is confirmed.

BERI-BERI IN THE DUTCH INDIES.

IT is officially stated that during the year 1885, there were 5388 persons in the Atchin colony treated for beriberi, of whom 235 died and 842 were incapacitated for duty Up to the present time no regulations seem to have had any effect on the ravages of this strange malady.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of November, 1886, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained rather more organic matter than the previous month's samples, although the actual amount present was in every case small for the season of the year. The water taken from the Lea and distributed by the New River and East London Companies also contained only a very small proportion of organic matter. All the waters were clear and bright on delivery.

DR. RAYNER'S plea, in *The Times*, for the treatment of mental disease at general hospitals deserves the attention of the profession. It is precisely what we have urged upon the consideration of our readers for many years past; but the subject has so many aspects that it cannot be at present adequately discussed.

DR. ALFRED MEADOWS has been elected an honorary member of the Washington Obstetrical and Gynæcological Society.

MR. CHARLES A. BALLANCE, M.S. Lond., F.R.C.S., has been elected Surgical Registrar to St. Thomas's Hospital, in the place of Mr. G. H. Makins, F.R.C.S., resigned.

THE *Deutsche Medicinische Wochenschrift*, which has hitherto been published by G. Reimer of Berlin, will now be published in Leipsig by G. Thieme.

The Lancet Sanitary Commission.

THE SANITARY CONDITION OF ROCHESTER.

ENGLAND has recently had much cause for congratulation that she has escaped the terrors of a disease which has visited with calamitous results France, Italy, and Spain. She has been able to regard with equanimity the possible introduction of cases of cholera into her midst, and has witnessed, without feeling the necessity for interference with her trade, the epidemic prevalence of this malady in continental seaports with which she is in constant communication. For this security she has undoubtedly paid a price, but the money expended has not procured for her safety in regard to this disease alone, but has given her inhabitants prolongation of life, and has raised the standard of health in all parts where the teachings of sanitary science have been allowed to prevail. But this security is not shared alike in all parts of the kingdom: in some, local authorities have striven to guard to the fullest the health interests of

Digitized by Google

those who are dependent on them; in others, there has been less willingness to incur the expenditure which is necessary for this purpose, and, strangely enough, amongst those which have been less active in this direction are localities that are more immediately exposed to risk of infection from without than are some others.

There are probably no towns more exposed to risks of the sort we have indicated than those which are situated on the waterside between London and the mouth of the Thames. Gravesend is known to be a special defaulter in this respect, but it by no means stands alone; the report recently issued by the Local Government Board gives but too grave an account of sanitary negligence in other districts of that neighbourhood. We have therefore thought it well to discuss in these columns the sanitary condition of other waterside towns in Kent, and we have directed our attention, in the first instance, to the towns of Rochester and Strood, which are situated respectively on the right and left banks of the river Medway.

Rochester forms part of a sanitary district which includes not only the parishes of St. Nicholas, Rochester, Precinct Cathedral, St. Margaret, and Chatham (*intra*) on the one side of the Medway, but also the parishes of Strood and Frindsbury on the other side of the river. The sanitary district is not therefore coterminous with either the registration districts of Medway or North Aylesford, but includes a part of each. The total population of the district numbered at the last census 21,307 persons, that on the right bank of the river being 14,240 in 2582 inhabited houses. During the year 1885 the death-rate for the whole district was 18·5 per 1000 of population; but if the deaths occurring in public institutions receiving patients from other districts be excluded, the rate is reduced to 14·9 per 1000. During this year, of a total of nine deaths from diphtheria in the whole district eight occurred in the Medway division, and of four total deaths from enteric fever three occurred in the Medway division. Of these two diseases, therefore, the Medway or Rochester division, as distinct from the North Aylesford or Strood division, suffered out of all proportion to the extent of population.

Rochester and Strood have shared with other towns the benefits of an improved water-supply. Thirty years ago two companies began to give facilities to the inhabitants for procuring water from deep wells in the chalk. Until this time the townspeople had nothing but wells in connexion with each house for their supply. These wells, situated in many instances in close proximity to cesspools, readily became contaminated, and proved a fertile source of disease to the inhabitants. Gradually the majority of these wells have been abandoned, and at the present time some three-fourths of the houses in Rochester and nine-tenths of the houses in Strood derive their water from the public supply. In 1880 the waterworks supplying the latter town passed into the hands of the Corporation, who thereupon expended £11,000 in their extension, and provided a sufficient quantity of water both for Strood and Frindsbury, and for more than three years a large majority of the houses in these three towns have been on constant service. The attention of the medical officer of health, Dr. Sladen-Knight, and of the surveyor, Mr. Banks, is being directed to the remaining houses receiving their water from local wells; maps have been prepared, showing for each the relative positions of wells and cesspools and the distance between them, and efforts are being made to induce the inhabitants to have their houses connected with the mains of the waterworks. Thus, during the year 1885, 117 samples of water were examined by the former officer, and some 60 wells were closed.

But while the local authority deserve credit for their recognition of the necessity of an ample supply of wholesome water, they have failed to keep pace with other towns in providing proper means for the disposal and removal of excremental matter. Speaking generally, the whole of the sanitary district depends solely upon cesspools. These receptacles vary from ten feet and more in depth. They are, as a rule, bricked, but must nevertheless afford ample means for the pollution of the soil beneath the towns. The smaller cesspools are emptied every year, but the larger retain their filth for four or five years. The contents are removed at night in buckets, which in some instances have to be conveyed through the houses to enable them to be emptied into the cart. The sanitary authority exercise little or no control over the operation, the inhabitants making their own arrangements with a contractor, who charges from £1 to £5 for the business of emptying each cesspool, the charge being proportioned according to its size. The surface-water is removed by means of drains, which discharge into the river Medway, and are carried on the foreshore to a position between high and low water mark. In some instances the inhabitants have connected their cesspools with these drains, and thus the overflow passes on to the banks of the river. The unsatisfactory nature of these arrangements appears to be well understood, and recently a firm of engineers submitted to the sanitary authorities of Rochester, Chatham, and Gillingham a scheme for the combined sewerage of these towns. It was proposed that the sewage should be utilised, and that the effluent, after purification, should be discharged into the Medway, not far remote from Gillingham. But the estimated expenditure proved a stumbling-block. The greatest opposition came from Chatham and Gillingham, and in the end the scheme was abandoned.

(To be continued.)

Pharmacology and Therapeutics.

MENTHOL PLASTER.

THE menthol plaster recently introduced into England by Messrs. Burroughs, Wellcome, and Co. for the American National Plaster Company is a good preparation. The specimen submitted to our inspection has the agreeable odour of peppermint, and indicates its nature also by the action of the menthol vapour on the conjunctivæ. We gave a plaster of it to a patient who complained of pain below the left breast. She expressed herself as greatly relieved by the application, which appeared to be more agreeable and to have greater effect than the belladonna plaster which she had previously worn. The writer applied a strip of the plaster to his brow whilst suffering from an attack of megrim. The action of the menthol was decidedly refreshing; it did not cure the headache, but seemed to abate its intensity, and even rendered movement less distressing.

ACETANILIDE, OR ANTIFEBRINE.

M. R. Lépine has published in the *Lyon Médicale* an account of a number of observations he has made both on animals and on patients of the action of this drug. He finds that it is a very valuable "nervine" in doses of seven and a half grains, producing as great an effect on the lightning pains of patients suffering from locomotor ataxy as a drachm or so of antipyrin. Like the latter, it lowers the temperature in fevers, and is preferred to antipyrine by patients because it does not produce a condition of semi-intoxication, as antipyrine in large doses is apt to do.

BICARBONATE OF SODA IN TONSILLITIS.

The treatment of tonsillitis by frequent local applications of carbonate of soda, which has been practised and recommended by Dr. D. Juan Giné, has been put to a series of tests by another Spanish physician, Dr. D. Rovira y Oliver, who deduces from them the opinion that, though it is often beneficial in cases where the parenchyma of the tonsil is affected, it is of much less value than many other applications in cases which are merely superficial, and catarrhal.

QUILLAJA SAPONARIA AS AN EXPECTORANT.

Dr. Maslovski has used the root of quillaja saponaria, which was recommended by Kobert, as a substitute for senega in a number of different pulmonary affections, and finds that it is a valuable expectorant. It is, however contra-indicated where hæmoptysis is present.

BENZOIN RESIN IN ULCERS.

Dr. Woskresenski, writing in the *Russkaya Meditsina* on the use of benzoin resin as a popular remedy for ulcers, says that he has frequently employed an ointment of the strength of four drachms to the ounce spread on lint, and renewed twice a day, with excellent results.

RESORCIN IN CONDYLOMATA AND MUCOUS PATCHES.

Dr. Gachkovski mentions in a Russian medical journal that he has applied resorcin as a dusting powder to thirty-four cases of acute condylomata which he has met with in the last five years, with the most satisfactory results. In one case where there were no less than thirty condylomata

Digitized by Google

on the prepuce, one of them as large as a raspberry, a daily application of resorcin reduced them all in the course of a week. Mucous patches, too, were easily cured by resorcin, though the cure was not permanent, as recurrence always took place.

TREATMENT OF ERYSIPELAS.

For the treatment of erysipelas Dr. Archangelski has tried a number of applications, and finds that their comparative efficiency is represented by arranging them in the following order: (1) benzoic acid; (2) tincture of iodine and turpentine, as ointment; (3) sulphate of copper; (4) sulphate of iron; (5) oxide of zinc; (6) naphthalin; (7) solution of perchloride of mercury, 1 to 300; (8) chloride of zinc; (9) iodoform.

CASCARA PASTILS.

The liquid extract of cascara sagrada though a valuable is not a palatable drug. Mr. Martindale has prepared some pastils containing the liquid extract. These gelatinous morsels can be rapidly swallowed without effecting the sensation of taste in any noticeable degree. That the pastils possess purgative properties we know from personal experience.

FORMIC ACID A DISINFECTANT.

Formic acid, according to Dr. Voitoff, who has made a number of experiments on cultures of pyogenic micro-organisms, is a specific against their success, and so may be considered as an excellent disinfectant.

THE COLLEGE OF PHYSICIANS AND MEDICAL DEGREES.

THE adjourned debate upon Dr. Allchin's amendment to the report of the Committee of Delegates upon Medical Degrees took place at the Royal College of Physicians on Dec. 23rd, Sir W. Jenner, Bart., President, in the chair. There was a large attendance of Fellows.

Sir H. PITMAN spoke first, and passed in review the previous resolutions of the College upon the subject, which, judging from the debate, he feared had been lost sight of by some of the Fellows. In 1884, upon the motion of Dr. Wilson Fox, the College referred to the Medical Bill Committee to consider how far it was desirable that the College should obtain powers to confer the title of Doctor of Medicine upon its Licentiates. To this resolution there was no opposition, the only material change being a further reference for suggestion of any other means whereby the alleged grievance to medical students, so thoroughly educated and examined, might be remedied. That Committee reported that it was desirable that increased facilities should be afforded for obtaining the degree of M.D., and recommended that the two Colleges should immediately take steps, either in co-operation with an existing University or by independent action, to secure this end. An interval now elapsed pending the scheme for the conjunction of the Colleges and its sanction by the Medical Council; and, this done, a further remarkable and instructive portion of the history of the question occurred. This was the reception of a letter from the Royal College of Surgeons requesting the College of Physicians to nominate seven delegates (later increased to ten) to meet the same number from their College, in order to determine what steps, if any, could be taken to enable the two Colleges to obtain the legal right of granting the title of Doctor to persons who have passed the examinations of the Conjoint Board. It was scarcely possible that the College of Surgeons would have proposed this unless they had known that the College of Physicians had previously viewed the matter favourably. No question was raised as to the desirability of this step, and the report of the delegates was now before the College. He thought the Fellows could hardly have recollected this history, when they were asked to assent to an amendment which was so adverse to the spirit in which the College had been acting. Moreover, the College had some time ago received a most influential memorial urging the combination of the Colleges to form one Royal College of Medicine with power to grant degrees. It was for the advantage of the profession, and it would be to the honour of the College by being useful to the profession, that the candidates approved by them should have something more than a bare qualification to practise. At the same time they could not object to any possible opposition. Naturally opposition might be expected from the Universities, for those who possess power are loth to see it shared by others. When Durham University was established it was opposed by Cambridge and Oxford. He did not believe that such opposition would arise from any feeling of jealousy of the Colleges; but he could understand that the Universities would be unwilling to see any degree granted on conditions less honourable than those of other bodies. In this he himself concurred, holding that a degree should be a distinction as well as a title. That was the question they had to settle. A degree would have to be obtained somewhere or other, whether through a teaching university or through the Colleges; and if a university were independently started in London, the Colleges would stand in a peculiar position with regard to it. Sir W. Gull's suggestion was opportune, for if they instituted an additional examination as the basis of the degree, the opposition of the Universities would be disarmed; and no doubt such a step would benefit the public as well as the profession, by stamping men as fully qualified in clinical medicine and surgery. The College owed a duty to the profession, but if it had to abandon the scheme, let it abandon it altogether. The College could of course change its opinion, but it had already gone too far to retreat with honour, and if it deserted the profession now it would do an injustice, and bring discredit on itself. If the College sought the powers and failed, it would have done its best to remedy this acknowledged grievance. But why should it not succeed? Some thought it anomalous for Colleges to grant degrees, but they forgot that the University of Edinburgh was founded as a College, and existed as such for over a century; and, to come down to modern times, they had seen instituted in London by Royal Charter a College of Music, with power to confer degrees of Bachelor, Master, and Doctor of Music. If a College can be instituted by Charter, why not a Medical Faculty? As regards the teaching university, it must be remembered that all things develop by degrees. They would endeavour to get power for the two Colleges to grant degrees in medicine, and other faculties would in time crystallise around them. But if they held their hands, and waited until a complete university was established, they might very possibly be left outside altogether, and would lose their acknowledged position at the head of medical education; and if they failed to grasp the present opportunity, their claim to deal with the question would be gone for ever.

Dr. MATTHEWS DUNCAN, whilst agreeing with nearly all of Sir H. Pitman's remarks, still maintained that the essence of the question had not yet been touched. The report contained statements which were far from being confirmed. It spoke of the "schools associated with the Colleges," but was it sure of the co-operation of the schools and of their hospitals? How could a teaching university be instituted without teachers? The project evidently aimed at such a university but there was no word as to its constitution, who were to form its senators, or in what relation the College councils were to stand to it. All were agreed as to the grievance, and that the Colleges would be honourably engaged in trying to remedy it, but there the difficulties of the question arose. They had to distinguish between a university and a college, and he held that a College such as this was distinct from a university, and its functions would be swamped in the new body. The College would lose its established position, and become a rival of other Universities. No doubt it would have done a great work, but it would be work foreign to the duties of the College; it would create a new body and would involve its own ruin.

Dr. ORD congratulated Dr. Allchin on his speech, but maintained that, although himself greatly interested in the work of the Teaching University Association, he could not support the amendment, for he felt that the Colleges, if they prosecuted this matter earnestly, would be working in harmony with the objects of the Association. The power and influence of the Colleges would be of great value in effecting this quickly; and it was in the belief that a university organisation would thus be originated that he urged the rejection of an amendment the effect of which was to stop all progress.

Sir ANDREW CLARK did not think that perfect unanimity could be expected, but considered that in discussing the principle it was important not to anticipate the details of a scheme. He warned the College that if Dr Allchin's amend-

Digitized by Google

ment were adopted it would be bound to apply to a university, and be quite unable to act independently; its offers might be rejected or might only be accepted on terms humiliating to the College. That it was unreasonable for the Colleges to become a university was no argument against the course proposed, which was urged on not only by practitioners, or by London teachers, but by a reasonable demand on the part of London students. The argument that the scheme was "without precedent" was made in ignorance of the history of universities. Was any precedent ever required to found a university? and as to the Colleges not representing the teaching body, were they not constituted of teachers? Nor would it be an "inferior degree," for had not the whole action of the Colleges been one to raise and improve the standard of medical education? He was sure that such training, particularly in clinical work, would be advanced and improved by this scheme. Nor would this be gained at the cost of the autonomy of the College. The degree would be given in unison with the College of Surgeons, and each College would retain, as at present, its individuality. The question should be dealt with on the ground not of what is theoretically desirable, but on what is just and practicable. It could not detract from the dignity of the College. If an institution such as theirs did not progress, it would certainly decay. He maintained that the grievance they had to remedy was a just one, and that it was reasonable and natural that it should be remedied by those who were at the head of the profession. If the Colleges did not seek the powers by themselves, they might be supported by a third body constituted by the State and representative of the schools; or a third alternative would be that shadowed forth in the amendment—affiliation with a university. The College was in the midst of a crisis, and he felt that if they were to be loyal to their inheritance and hand down its traditions unimpaired, they must take the lead in this great movement.

Dr. STURGES asked for a definition of the phrase "Arts or Science" in the resolution, and was proceeding to criticise a previous report suggesting details of a proposed Arts examination, when it was pointed out that the College had not at present considered such details.

Dr. QUAIN contended that Dr. Allchin's amendment did not point out how the object they aimed at was to be secured. The College was bound to give a degree, and the details of the scheme could be referred for further consideration.

Sir RISDON BENNETT said his loyalty to the College and anxiety on its behalf prevented him accepting the resolution of the delegates. He thought that if the opportunity now before them of acquiring these powers were lost for ever, it would be to the advantage of the College; yet he quite admitted there was a grievance, and that it was the duty of the College to assist in getting rid of it. He could vote for the second resolution, which involved an application for powers to grant degrees, but could not concur in the details of the first resolution. He would consent to nothing which touched on the rights and privileges of the College, and he maintained that the first effect of creating a new class of graduates would be to break down the partition between the Licentiates and the Members, and would entirely alter the value of the Fellowship. How could this be done without converting the College into a new-fangled university, with the consequent loss of its prestige? Whatever is done, it must tend to raise the examinations, and would lead to the establishment of an inferior body, whilst doing away with one high-class examination. He felt that they were very imperfectly acquainted with the probable outcome of such a scheme.

Dr. DICKINSON said there was a great work before the College, and that if they obtained powers to confer a degree, it must be a worthy one, embracing a higher examination in Arts, a clinical examination, and a requirement that candidates should have had part of their education in London.

Dr. LATHAM had formerly opposed the project, but had been converted to it, and hoped that, for the advantage of the general public, of the medical students in London, of the Colleges of Physicians and Surgeons, and especially of the old Universities, it would be carried into effect. He believed that any opposition that might come from the old Universities would proceed from a sentimental grievance, and that they would hold their own ground. The graduates of the Universities were proud to become Fellows of the College; and was there any reason why that relationship should not be still maintained? Were not the two Colleges in a better position to judge of medical education than the small bodies of the Universities; and would they not seek to maintain the standard of medical learning; whilst they certainly could not lower the value of University degrees?

Dr. BARNES said that it was wrong to fear that the Colleges would suffer in reputation by taking this course. If they have a leading part in the project, how could they suffer degradation? They had gone too far to retire with any decency or safety. He held that medical education was superior in London, and the student life in London could be compared with the life at a University.

Sir W. GULL said it was the duty of the College to advance the profession of medicine, and to minister to its wants. If students are driven away from London for want of a degree, the Colleges should meet this. They had already accepted this, and had to consider on what terms such a degree should be given. He suggested the title of M.D. Lond. as one worthy of adoption, that of M.D. Univ. Lond. standing for the present University. The time had come for granting a degree on professional merits.

Dr. BROADBENT pointed out that the question was whether they were going to delegate this power to others or do it themselves. If the College decided not to take powers, according to the amendment, then the whole question would fall. If the decision were otherwise, then they must expect that all who now objected would co-operate to make the degrees worthy of the Colleges. To all intents and purposes, the Colleges at present exercised the functions of a medical university; so that the step proposed was merely a further development of their powers, the real revolution being when the College began to examine Licentiates. That action of the College had raised the whole tone of medical education. If the amendment were carried, another body would be called into existence, and the Colleges would sink into a secondary place.

Dr. PRIESTLEY had been much influenced by Sir H. Pitman's speech, and having no doubt that this would be the starting point of a new university, he should support the resolution.

The College then divided, and Dr. Allchin's amendment was rejected by a large majority, only nine Fellows voting in its favour.

Dr. BROADBENT moved, and Sir W. GULL seconded, the next resolution—viz., "That an application be made to the Crown by the Royal College of Physicians of London and the Royal College of Surgeons of England, acting conjointly, for power to confer degrees in medicine and surgery." This was unanimously acceded to, and a further motion referring the resolutions and Sir W. Gull's amendment to the Committee of Delegates was also carried, on the motion of Dr. Quain, seconded by Dr. Priestley.

DONATIONS AND LEGACIES TO MEDICAL CHARITIES IN 1886.

THE following is a list of the principal legacies and gifts during the past year to the various medical charities and institutions of Great Britain:—Mrs. Mary Anne Curwen (in default of her daughter having issue), £40,000 to St. George's Hospital, £5000 each to two and £2500 each to about twenty other London medical charities; Mr. Richard Henry Vade Walpole, over £185,000, in equal shares, to the Westminster Hospital, Charing-cross Hospital, King's College Hospital, St. Mary's Hospital, the London Hospital, the Royal Free Hospital, the London Fever Hospital, the City of London Hospital for Diseases of the Chest, the Norfolk and Norwich Hospital, the Cheltenham Hospital, the Great Yarmouth Hospital, and the British and Foreign Sailors' Home, Great Yarmouth; Mr. Henry Chisley of Hastings, £13,650 to the London Hospital; Alderman Thomas Rose, Manchester, £10,000 to the Manchester Royal Infirmary, £5000 to the Salford Hospital, £2000 to St. Mary's Hospital for Women, Manchester, and £1000 each to the local Eye, Lock, and Clinical Hospitals; Mr. James M'Ewan, £5000 each to the Glasgow Royal Infirmary and the Western Infirmary, Glasgow; Mr. Beardwood, £5000 to the Blackburn and East Lancashire Infirmary; Mr. Alfred Burges, Worthing, £3500 to such institutions or societies as his trustees shall think

Digitized by Google

fit; Miss Mary Elizabeth Tanner, £3000 to the Royal Hospital for Incurables, Putney, and £500 to the German Hospital, Dalston; Mr. Charles Johnson da Silva, such part of the residue of his personal property as may by law be applied for charitable purposes to the Royal Medical Benevolent College, to found three exhibitions of £50 per annum, each tenable for three years, for boys educated at the College and proceeding to the Universities, and to pay £20 per annum each to twenty-six poor pensioners of the said College; Mr. William de Hague, £3000 each to St. George's Hospital, the Middlesex Hospital, the London Hospital, the Hospital for Incurables at Putney, the Westminster Hospital, and the City of London Hospital for Diseases of the Chest; Mrs. Mary Gatley Litler, £1000 each to the National Hospital for the Paralysed and Epileptic, Queen's-square, Bloomsbury, and the Royal Hospital for Incurables at Putney, and £500 to the Warneford Hospital, Leamington; Harvey Kimpton Owen, M.D., F.R.C.S., £1800 to the Royal Medical Benevolent College at Epsom to found a scholarship, and £500 to the British Medical Benevolent Fund; Mr. William Augustus Guy, M.B., F.R.S., F.R.C.S., £250 each to King's College Hospital and King's College Hospital Convalescent Institution, and on the death of his wife, or twenty-one years after his decease, whichever happens first, one-half of a moiety of the residue of his real and personal estate which is left in trust for accumulation in the meantime to King's College Hospital Convalescent Institution; Mr. Samuel Taylor, £1050 to the Bedford General Infirmary; Mr. Thomas Phillip Danson, £1000 to the Endowment Fund of the Bootle Borough Hospital and £500 to the Liverpool dispensaries; Mr. Henry Boddington, £1000 to the Manchester Royal Infirmary and Dispensary; Mrs. Harriett Anne Richardson, £1000 to the Hospital of St. John of Jerusalem and St. Elizabeth, Ormond-street; Mr. Richard Towne, £1000 to the National Orthopædic Hospital; Mr. Joseph Stevens, £1000 to the Nottingham General Hospital and £500 to the Midlands Institution for the Blind, Nottingham; the Right. Hon. Katherine Anne Viscountess Cranley, one moiety of £1000 Consols to the Brompton Hospital for Consumption; Mr. Abraham Altham, £500 towards erecting a children's ward at the Victoria Hospital, Burnley, and £500 to the endowment fund of the said hospital; Mr. James Fletcher, £500 to the Northern Infirmary, Inverness; Mrs. Frances Acton, £500 to the Royal Hospital for Incurables, Putney; Dame Anna Maria Hare-Clarges, £500 each to the Putney Hospital for Incurables and the Taunton Hospital, Somersetshire; Mr. Foster Connor, £500 to the Belfast Royal Hospital; and Mr. Charles Charlesworth, £500 to the Bradford Fever Hospital. In respect to donations, Mr. Philip Horsman defrayed the cost (about £4000) of the in-patient department of the new Eye Infirmary at Wolverhampton; the Duke of Westminster contributed £1000 to the Hospital for Women, Soho-square; Miss Cooper of Southport, £500 to the endowment fund of the children's ward at the local hospital; and Mrs. Booth, £500 to the Manchester Clinical Hospital for Women and Children.

CHRISTMAS FESTIVITIES IN THE HOSPITALS.

Charing-cross Hospital.—The annual Christmas entertainment to the inmates of this hospital was given on the 17th ult., when the principal item in the performances was Mr. Maddison Morton's rather old-fashioned, but interesting little comic drama, "A Husband to Order," which was acted with care and judgment, and was received with the heartiest demonstrations of approval. An amateur orchestra of strings and pianoforte performed a selection of music during the evening, and in the interval between the performances the visitors made a tour of inspection through the wards of the institution.

Guy's Hospital.—In accordance with the annual custom, Mr. E. H. Lushington, the treasurer, and Dr. Steele, the medical superintendent of this institution, accompanied by a party of visitors, made a tour through the wards of the hospital at dinner-time on Christmas Day. The effect of the lack of funds at this institution was, to some extent, perceptible in an increased number of empty beds, and in the diminished display of evergreens in one or two of the wings of the hospital, but otherwise Christmas was as gaily kept up as in other years. The dinner, consisting of roast beef, turkey, plum pudding, and dessert, was served promptly at one o'clock, and apparently enjoyed by the inmates. In all the wards there were Christmas trees, and in the evening concerts were improvised in the wards in which the attendant noise could safely be permitted.

St. Thomas's Hospital.—The Christmas dinner at this hospital consisted of beef, weighing over 300 lb., and plum pudding, weighing 475 lb. The wards were all artistically and tastefully decorated with flags and evergreens. In the Victoria ward, solely occupied by children of tender age, were two large Christmas trees, the toys from which were distributed to the convalescent children on the 27th ult. In the evening carols were sung by the probationer nurses in all the wards with the exception of the Victoria, and the efforts of the staff to render their Christmas Day as enjoyable as possible seemed to be fully appreciated by the sick inmates of the institution.

Royal Free Hospital, Gray's-inn-road.—The various wards of this hospital presented a very pleasing appearance, the nurses and convalescent patients having decorated them with holly, evergreens, mottoes, and Scriptural texts. On the morning of Christmas Day the usual short service was held in each ward, and carols and hymns were sung. The patients were allowed to receive visitors at any time of the day and various extras were permitted. In the evening the convalescent patients, with their friends, had an entertainment in the Calthorpe ward, in which the medical staff and nurses took part.

Seamen's Hospital (late Dreadnought), Greenwich.—At this hospital a Christmas dinner, consisting of turkeys, pheasants, plum pudding, &c., was served to 202 patients. Of this number 126 were natives of Great Britain and Ireland, 20 were Norwegians, 12 Swedes, 12 Germans, 6 Fins, 4 Russians, 4 Frenchmen, and 4 natives of the West Indies, 5 citizens of the United States of America, 3 Danes, and 3 Portuguese, while Austria-Hungary, New Zealand, and St. Helena had each a representative. On the 28th ult. a conjuring entertainment and concert was given by the officers of the institution and their friends for the amusement of the nurses and servants, and on the 29th the same performance was repeated for the benefit of the patients.

The London Hospital.—At this hospital, which has room for nearly 900 beds, there were on Christmas Day 592 in-patients distributed over some fifty wards, the whole of which were decorated, and special fare was provided. The children were specially cared for in the way of toys, sweets, &c., and carol-singing was indulged in at intervals throughout the day.

North-Eastern Hospital for Children, Hackney-road; East London Hospital for Children; the German Hospital; and the Hospital for Diseases of the Chest, Victoria-park.—At all of these institutions there were the usual Christmas festivities and indulgence. The wards were decorated, special fare was provided, and toys distributed to the juvenile inmates.

University College Hospital.—The usual Christmas entertainment at this institution took place on the 29th ult., when the children were entertained by a Punch and Judy show, and the adults by a miscellaneous performance. Mr. Corney Grain, who kindly gave his services for the occasion, amused a large gathering of patients and visitors with a musical sketch, and Mr. Horace Chester gave a musical and mimetic entertainment entitled "Broad Grins." Later on a miscellaneous concert was held. The wards were effectively decorated with holly and evergreens, and all the children were presented with toys. Money has in addition been collected to enable welcome gifts of hats, boots, and clothing to be made to other patients.

Mr. Barnardo's Homes.—A Christmas dinner was given to all the inmates of the London branches of these homes, and afterwards sundry prizes for good conduct and diligence during the year were presented. In the evening a general Christmas entertainment was given, which met with evident and well-deserved appreciation.

THE MODE OF CAPITAL PUNISHMENT.—The New York Legislature at its recent session appointed a commission to investigate and report upon the most practical and humane method known to modern science of carrying into effect the sentence of death in capital cases. The present method of execution by hanging is for many reasons repulsive to the citizens of New York, and the report of the commission is awaited with considerable interest.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sunderland.—This borough is now estimated to contain nearly 125,300 people. The birth-rate of 37·7 per 1000 exhibits a decline; that of deaths, which was 23·7, shows a slight increase; and Mr. Harris, in an interesting study of the value of statistics as affecting Sunderland, urges that when correctly apprehended they indicate the need for further waging war against every circumstance that leads in any degree to interfere with the health of the community. Already a decrease in the infantile and in the diarrhœa mortality tends to show that results have been obtained from the improvements effected in the sanitary condition of the town, and householders are urged to second the efforts of the authority in the matter of disposing of vegetable and other house refuse by burning. With regard to the zymotic diseases, small-pox, diphtheria, and measles were the only three that during 1885 showed any excess over the average for the preceding ten years. The borough Act compelling the notification of infectious diseases, only came into operation in the latter half of the year. The cases of small-pox numbered 126, and of these 17 died. Of 98 vaccinated persons attacked 2, or 2·04 per cent. died; whereas of 17 unvaccinated persons 5, or 29·4 per cent., died. In 11 cases nothing could be seen or heard of vaccination, and of these 99·9 per cent. died. In only three cases did small-pox attack revaccinated persons, and in each cese the revaccination was performed after the patients had contracted the poison of small-pox. Measles is known to have caused 1310 cases and 385 deaths; and it became an important question at one time whether the elementary schools should not be closed. But Mr. Harris felt that the evils of this course might, at the stage of the epidemic in question, exceed any good that could result, and in this view he was supported by the medical officer of the Local Government Board, to whom the facts were submitted. Diphtheria caused 12 deaths, but this only just exceeded the average. During the year 183 patients were removed to hospital, including 105 from small-pox and 46 from typhus. Unfortunately hospital isolation has for years past been greatly hindered in Sunderland, owing to the permanent retention of a temporary arrangement inaugurated under the influence of panic; but steps are now well forward for providing a hospital in every way creditable to the borough. Space prevents our doing more than giving a superficial summary of Mr. Harris's report, which is one of the most comprehensive and carefully prepared documents which have recently come under our notice.

Hull.—During 1885 the birth- and death-rates for this borough were 33·7 and 17·3 per 1000 living respectively, the population being 186,292. Both the general and the zymotic death-rates were exceptionally low, the latter only amounting to 1·06 per 1000, and the infant mortality was only 127 per 1000 registered births, as opposed to 155 for England and Wales as a whole. Of the zymotic deaths diarrhœa was the most fatal, 59 deaths resulting from it; but this was by no means a large number when contrasted with previous years. Great interest, however, attached to an attack of diarrhœa in the borough, which occurred during the exceptional month of March, 1885, and which was believed to have been associated with the pollution of the Hull water-service. Suddenly, on the 21st of the month, and "like a storm," diarrhœa manifested itself in Hull, and by April 5th, when the disease subsided, no less than from 18,000 to 20,000 persons had been attacked. The outbreak was peculiar in its special incidence on adults, but very few children in the affected areas were attacked. The characteristic symptoms were purging, vomiting, and pain in the bowels, attended with great prostration. But the mortality was trivial. The comparative absence of the disease amongst those of old age and in youth is regarded by Dr. Mason as pointing to the fact that the poison expended itself mainly on that portion of the intestines occupied by Peyer's patches. The cause of the outbreak is explained as having been due to the admission into the Hull water service, during certain operations at the works, of polluted and noxious matters from a beck and from Wood's drain; these receiving some of the drainage from the village of Willerby and the drainage from a farmstead. The disease, although in the first instance limited to houses supplied by the Hull water, or to persons using that water either in their own houses or elsewhere, subsequently indicated its contagiousness by spreading in the houses of persons who had drunk the water at their places of business and elsewhere than at home; but the question as to the origin of the infection is, unfortunately, dismissed in a few words, to the effect that there was possible contamination of the Hull water by admission into it of the excreta of persons suffering from diarrhœa just anterior to the epidemic. During the year 261 patients were admitted into the isolation hospitals. These are inefficient, and a ground plan is submitted in the report showing a new sanatorium which is in contemplation. The arrangement indicated appears to us defective, in so far as all persons entering the grounds must pass by the wash-house, one of the most infected of all hospital buildings, before reaching the administrative block, the approach to which should always be so arranged that persons passing to it will have no chance of communicating with those who deal with infected articles. There appears also to be, in connexion with the administrative building, which should be kept free from infection, a ward for probationers. This is a mistake, for probationers need as much isolation as those whose diseases have been fully recognised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 4589 births and 3745 deaths were registered during the week ending Dec. 25th. The annual death-rate in these towns, which had been equal to 22·9 and 20·7 per 1000 in the preceding two weeks, rose again last week to 21·4. During the first twelve weeks of the current quarter the death-rate in these towns averaged 19·9 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 11·7 in Brighton, 18·1 in Birmingham, 18·1 in Birkenhead, and 18·6 in Sheffield. The rates in the other towns ranged upwards to 29·4 in Manchester, 30·0 in Plymouth, 30·7 in Wolverhampton, and 31·9 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 424 and 386 in the preceding two weeks, rose again last week to 433; they included 182 from measles, 71 from scarlet fever, 75 from whooping-cough, 34 from "fever" (principally enteric), 31 from diphtheria, 40 from diarrhœa, and not one from small-pox. No death from any of these zymotic diseases was registered last week in Derby; whereas they caused the highest death-rates in Leeds, Halifax, and Wolverhampton. The greatest mortality from measles occurred in Cardiff, Leeds, Halifax, and Wolverhampton; from whooping-cough in Manchester, Bradford, Plymouth, and Huddersfield; from scarlet fever in Newcastle-upon-Tyne, Bristol, and Salford; and from "fever" in Preston. The 31 deaths from diphtheria in the twenty-eight towns included 17 in London, 3 in Portsmouth, 3 in Bristol, and 4 in Liverpool. No death from small-pox was registered in London and its outer ring, or in any of the twenty-seven large provincial towns. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 494 and 415 in the preceding two weeks, were last week 436, and were 93 below the corrected weekly average. The causes of 95, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol. The largest proportions of uncertified deaths were registered in Huddersfield, Brighton, Blackburn, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·0 and 22·5 per 1000 in the preceding two weeks, further rose to 26·2 in the week ending Dec. 25th; this rate was 4·7 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·5 and 18·0 in Leith and Perth, to 24·8 in Aberdeen and 32·2 in

Digitized by Google

Glasgow. The 648 deaths in the eight towns last week showed a further increase of 92 upon the numbers in the previous two weeks, and included 15 which were referred to whooping-cough, 13 to measles, 13 to scarlet fever, 11 to diarrhœa, 7 to diphtheria, 4 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all 63 deaths resulted from these principal zymotic diseases, against 81, 63, and 75 in the preceding three weeks. These 63 deaths were equal to an annual rate of 2·4 per 1000, which was 0·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 15 and 19 in the previous two weeks, declined again last week to 15, of which 10 occurred in Glasgow and 4 in Aberdeen. The 13 deaths from measles (of which 12 were returned in Glasgow) showed a further increase upon recent weekly numbers. The fatal cases of scarlet fever, however, which had been 25, 17, and 16 in the previous three weeks, further declined last week to 13, and included 8 in Glasgow and 2 in Aberdeen. The 11 deaths attributed to diarrhœa, of which 5 occurred in Glasgow and 3 in Paisley, showed a further decline from recent weekly numbers. The 7 deaths from diphtheria, including 3 in Edinburgh and 2 in Glasgow, exceeded those in the previous week by 1; while the 4 referred to "fever," of which 2 occurred in Edinburgh, showed a decline of 7. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding four weeks from 125 to 174, further rose last week to 188, and exceeded by 37 the number in the corresponding week of last year. The causes of 89, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 35·6 and 29·6 per 1000 in the preceding two weeks, further declined to 28·5 in the week ending Dec. 25th. During the first twelve weeks of the current quarter the death-rate in the city averaged 25·9; the mean rate during the same period did not exceed 18·4 in London and 19·1 in Edinburgh. The 193 deaths in Dublin last week showed a further decline of 7 from the high numbers in the previous two weeks, and included 6 which were referred to scarlet fever, 6 to whooping-cough, 5 to "fever" (typhus, enteric, or simple), 3 to diarrhœa, 1 to diphtheria, and not one either to small-pox or measles. Thus 21 deaths resulted from these principal zymotic diseases, against 23 and 22 in the previous two weeks; they were equal to an annual rate of 3·1 per 1000, the rates from the same diseases being but 2·1 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough and scarlet fever showed an increase upon the numbers in the previous week; whereas those referred to "fever" and diarrhœa had declined. Six inquest cases and 5 deaths from violence were registered; and 61, or nearly a third, of the deaths occurred in public institutions. The deaths of infants showed a considerable decline, while those of elderly persons exceeded those returned in the previous week. The causes of 31, or 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Sir Samuel Rowe, M.B., K.C.M.G., from the Seconded List, to be Surgeon-Major. This gentleman has also been granted retired pay, with the honorary rank of Brigade Surgeon.

RIFLE VOLUNTEERS.—3rd Volunteer Battalion, the Lancashire Fusiliers: Acting Surgeon Richard Crean, M.D., to be Surgeon.—1st Midlothian (Leith): Surgeon and Honorary Surgeon-Major James Struthers, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement.—4th Middlesex (West London): Surgeon and Honorary Surgeon-Major G. E. Norton resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement.—5th Lancashire (the Liverpool Rifle Volunteer Brigade): Acting Surgeon G. W. Steeves resigns his appointment.

VOLUNTEER MEDICAL STAFF CORPS.—London Division: Henry Work Dodd, Gent., to be Surgeon.

Correspondence.

"Audi alteram partem."

MR. SAVORY'S PAPER ON LIGATURE OF THE FEMORAL ARTERY.

To the Editors of THE LANCET.

SIRS,—I am indebted to Mr. Holmes for calling attention to the accidental omission of a few important words in the short abstract of my paper lately read before the Medical and Chirurgical Society, for which I alone am responsible. Instead of "the artery is pervious throughout," it should of course have been "the portion of the artery between the ligature and the sac is pervious throughout," &c. I can only hope that the omission was too obvious to mislead any one. The point is, I think, made clear enough in the paper itself. The title of this is, "On the Effect upon the Femoral Artery of its Ligature for the cure of Popliteal Aneurysm," and it opens thus: "When the femoral artery is tied at the apex of Scarpa's triangle for the cure of popliteal aneurysm, what effect is produced on the vessel *between the point of ligature and the sac?*" I say in my paper that I think the majority of surgeons will hardly be prepared for the conclusion which is to be drawn from the facts I report. It need not be said that I may be wrong in this; but I confess it is an impression I still retain. I cannot here of course refer at length to evidence of this; but when Mr. Holmes says it is stated in every text-book that the artery remains pervious from the ligature to the aneurysm, it may be enough if I answer him with a single passage from one of the most recent and important works on surgery. When the superficial femoral is tied in Scarpa's triangle for popliteal aneurysm, "the artery very often becomes occluded by coagulum from the ligature to the aneurysm, and beyond it to the first large branch below, while in other cases a certain portion of that length remains pervious. After a little time the aneurysm and the obliterated vessel undergo a process of contraction and absorption, so that they come to resemble a solid cord with a knot on it." In the discussion which followed, I meant to say, in the remarks to which Mr. Holmes refers, that I do not remember to have seen in any work the facts (as I find them) stated correctly. The passages in his own works, which Mr. Holmes quotes, would, it seems to me, hardly convey the idea that the portion of artery between the ligature and sac was, in the majority of cases, pervious throughout.—I am, Sirs, yours obediently,

Brook-street, W., Dec. 28th, 1886. W. S. SAVORY.

THE DENSITY OF THE TEETH AS INFLUENCED BY THE FOOD, ETC.

To the Editors of THE LANCET.

SIRS,—"Every dental surgeon knows that the hardness of the teeth may vary greatly in the same individuals at different periods; the most marked, although by no means the only cases, are those of pregnant women; and this cannot be explained solely on the ground that the secretions of the mouth are vitiated by reduced acid from gastric disturbance. There is undoubtedly an absolute softening of the whole tooth substance, due, probably, to the robbing of the teeth of the mother of their lime salts in order to build up the osseous system of the fœtus." This extract (apparently a quotation from the writings of Dr. Miller of Berlin) occurs in an annotation in THE LANCET of Dec. 18th. It is certainly not the case that every dental surgeon adopts these statements as true; and I venture to affirm it will be difficult to find one competent authority who will accept any or either of them. It is hardly possible to imagine the occurrence of degenerative or nutritive changes in a tissue like enamel—the tissue in which caries begins. To believe in such changes we must first conceive of some means by which this calcareous substance, as dense as quartz and devoid of cellular elements, could assimilate nutritive material when conveyed to it; and we must next imagine the conveyance of new and effete material to and from the vessels of the pulp, through the odontoblast layer of the pulp, and through the dentinal fibrils to its destination

Digitized by Google

in the enamel. The evidence is overwhelming that dental caries is due entirely to external agents; that enamel and dentine are perfectly passive under the process of disintegration; manifesting neither pathological action nor vital reaction of any kind. A dead tooth replaced in the mouth as an artificial substitute is just as liable to caries as its living neighbours; when it is attacked decay begins in those situations where it would be most liable to disease were it living, and the decay is true dental caries, identical in every way with the disease in living teeth. There exist three demonstrated predisposing causes of caries which enable us to understand clearly its common association with diseases and cachexiæ. Given, 1st, innate structural imperfections in the tissues—from which few sets of teeth are free,—varying infinitely in different individuals; 2ndly, crowding and irregularity of the teeth, equally varying in degree; and 3rdly, vitiation of the secretions of the mouth, not only varying in amount, but highly irregular in its appearance and duration through the life of different individuals—and the facts are fully accounted for without the invention of the questionable hypotheses which Dr. Miller has adopted. These hypotheses, which were held by early writers before the anatomy of the teeth was made out, have not been supported by investigators working in the light of modern science. They have, however, recently been revived by some few American writers. Some of these state that they have been enabled to demonstrate the presence of a distinct substance between the prisms of enamel, having stained the tissue with chloride of gold. On the strength of this they write of a "complete network of protoplasm extending from the pulp to the surface of the enamel." If such a substance do exist, it must be in a condition of extreme tenuity, and it is impossible to accept the gratuitous and unnecessary hypothesis that this trace of organic matter is a medium through which nutrition as well as gross degenerative changes are brought about in enamel.

I am, Sirs, your obedient servant,

Wimpole-street, Dec. 20th, 1886. HENRY SEWILL.

*** To open up our columns to a discussion on the causes of dental caries is not possible on account of want of space. It is a subject which is as yet by no means satisfactorily explained; but Mr. Sewill's theory that the teeth only play a passive part has very few supporters (*vide* a discussion at the Odontological Society some time ago). Experiments like those of Dr. Miller will doubtless clear up many points that are now difficult of explanation. In our annotation, tenth line, "vitiated by reduced acid from gastric disturbance" should read "vitiated or rendered acid by gastric disturbance."—ED. L.

THE RELATIONS OF MEDICAL PRACTITIONERS TO THEIR PATIENTS.

To the Editors of THE LANCET.

SIRS,—In your issue of December 25th, in an annotation on "The Lessons of the Campbell Case," you draw attention once again to the folly of practitioners making friends of patients (clients). Few of any experience in the working of general practices will be found ready to dispute this point. A well-nigh twenty years' personal experience, during the whole of which time I have been a keen observer of the ways of other practitioners, has demonstrated to me, over and over again, the wisdom of your strictures. The Campbell Case gives, of course, an extreme example of the complications which such friendships may lead a man into, but many, and many a time, have I seen good-paying patients lost to excellent practitioners over some trivial matter, which a strict professional bearing during the whole period of medical adviserships would have entirely obviated. At the same time, and this is what I wish to find out, how is a general practitioner (a provincial or country one at all events) to avoid the difficulty? He is truly between two stools—if he does not make friends (socially) his practice does not develop, and he is said to be a 'proud' man; if he does make friends, he very likely makes clients (patients) of them ultimately, but his very friendship, undoubtedly, puts him in constant danger of losing them. Many a tradesman's and farmer's family have I lost as patients because they became friendly with some neighbouring practitioner and his family. On the other hand, one's better class farmer clients are seldom or never attracted unless through a previous acquaintance of more or less friendly intimacy; and unless this is kept up, they will in nine cases out of ten discontinue to employ you. In these days of depression a farmer of fair middle class education, and *with money*, is a power in country districts, and he knows it, nor does he hesitate to exercise his adverse influence, if he feels aggrieved with his doctor, his parson, or his lawyer, politically, municipally, or ecclesiastically.

Finally, I do not write as a disappointed practitioner. I have a fair practice with good appointments, and I have made money at it. I may also state that I am a gentleman's (a widely-known man) son, and have had a liberal education in both general and professional subjects. I enclose my card.

I am, Sirs, yours truly,

Dec. 27th, 1886. GENERAL PRACTITIONER.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE NEW CHILDREN'S HOSPITAL IN NEWCASTLE.

AT a late meeting of the governors of the Children's Hospital, held in Newcastle last week, it was stated that the contract was ready to sign with the builder, and that all legal formalities were now complete. It was announced that the new buildings, apart from the land, would cost £15,000, all provided by the munificence of Mr. John Fleming, of this city. The plans which were exhibited, showed an entrance hall twenty feet square; close to which will be a committee-room, housekeeper's sitting-room, linen, and work room, and matron's room. These are to the right of the entrance hall, and to the left will be a waiting-room, porter's room, consulting room, drug stores, surgery, and medical officer's room, the last being provided in view of the possibility of a resident medical officer being appointed at some time or other. Facing the entrance hall will be a spacious dining-room, and beyond that will be rooms for the necessary domestic work. On the first floor, over the entrance hall, will be a day ward, and play room. To the right will be a small ward, a nurse's room, and a large general ward for girls, twenty of whom may be accommodated there. To the left will be a similar provision for boys. There will also be isolation wards, an operating room, and other necessary conveniences, while the second floor will be used as nurses' and servants' bedrooms. The front, which will have an imposing appearance, will be of red brick with stone dressings, and a belfry over the main doorway.

DEATH OF MR. ALFRED ROBSON BENSON, M.R.C.S., OF WHITBY.

I regret to announce the death, on the 9th of December, after a rather long illness, of Mr. A. R. Benson, M.R.C.S., of Whitby, Yorks, at the age of seventy-two. Mr. Benson held, for many years, an appointment in the Hudson Bay Company's Service at Fort York, Columbia River, Vancouver's Island. Whilst at Vancouver's Fort, Mr. Benson became intimate with the late General Grant, then a captain in the United States Army. He frequently made journeys into the interior amongst the Indians with whom he had much influence. Mr. Benson returned to England about twenty years ago, and settled in his native place, Whitby. He did not practise after his return, but was ever willing to advise the poor. He was known as an authority on local and genealogical history, being himself a member of one of the oldest families in Whitby. He was a genial and kind-hearted man, whose portly form and friendly greeting will be missed by many.

A NEWCASTLE DOCTOR IN BURMAH.

The special war correspondent of the *Allahabad Pioneer and Indian Mail* of the late date says, that after four days of hard marching, Yemethen was reached. The men were very much fatigued and pulled down by fever and sickness, and from exposure to rain; and, had it not been for the unremitting efforts of Surgeon Nichol, Medical Staff, 3rd Brigade, who always had his medicines ready to dispense hourly to a long line of patients who streamed in daily after a long march, our lines would have been sadly weakened. Dr. Nichol is intimately connected with Newcastle, and it will be a pleasure to his many friends to see this honourable mention of his name from the Indian newspaper.

POLICEMEN AS MEDICAL "EXPERTS."

Unless there is some change in the mode of conducting coroner's inquests, people will begin to ask what is their use; for instance, an inquest was held in Newcastle last week on the body of an itinerant dealer in medicine, or "Quack Doctor," who was found dead in his bed in his lodgings. A policeman deposed that he forced open the bedroom door, and found the body lying on a bed. On a chair he found a bottle (produced); and also a tumbler half full of water. The policeman further said that the bottle and glass had a similar smell—that of laudanum. Upon this very "conclusive" evidence as to poisoning, the jury returned a verdict to the effect that the deceased was found dead in his bed, but that the evidence was not sufficient to show whether death was due to natural causes, or to poisoning. The question naturally presenting itself in regard to this loose verdict is, why—if evidence was required only to show the cause of death—no medical man was called.

Newcastle-on-Tyne, Dec. 27th.

MANCHESTER.

(From our own Correspondent.)

VICTORIA UNIVERSITY.

THE financial condition of the Victoria University is at present by no means what it is desirable it should be, and it is therefore satisfactory to note that some of our citizens are not unmindful of its wants, as shown by the acquisition to its funds of £1000 under the will of the late Mr. Boddington. At the last meeting of the Leeds Town Council it was decided to support the application to the Government for an annual grant in aid of the University funds. Leeds will probably be the next place to become affiliated to the University. Much surprise has been expressed at the rumoured proposal to affiliate University College, London, to the Victoria University. No greater reflection than this can be made upon the present regulations in force at the London University, and it shows how keenly the want of facilities for London students to obtain a medical degree is felt at the present time. Amongst the external examiners appointed by the Council on Dec. 16th, one was from Scotland, one from Ireland, and one from London.

ROYAL INFIRMARY.

This institution also received £1000 under the above-mentioned will, and smaller legacies were left to many of the other hospitals, but amongst the numerous bequests and donations made to our various medical charities, the Ancoats Hospital, which is doing good and useful work in one of the poorest parts of Manchester, appears to be singularly overlooked. A little more prominence and "pushing to the front" on the part of those connected with this institution would probably remedy this apparent neglect. What appears to have been a case of hydrophobia from a cat's bite was recently admitted to the infirmary wards. The man was bitten some four months ago on the right hand by a cat; about a week before his admission he complained of much pain up the arm, and rapidly became worse, and was only brought to the infirmary a few hours before his death. It would have been more conclusive as to the real character of the disease had some corroborative evidence been obtained by experiment on one of the lower animals.

INFANT MORTALITY.

A deplorable loss of infant life appears to be going on. The coroner, when holding an inquest in Salford recently on the body of a child that had been overlain by its mother, said that within the previous week or so he had held inquests on about a dozen infants who had thus been found dead in bed.

Manchester, Dec. 20th, 1886.

THE JACOB TESTIMONIAL.—The executive committee met on Wednesday, Dec. 29th, Sir Wm. Stokes, President of the Royal College of Surgeons in Ireland, in the chair. Subscriptions amounting to over £90 were announced by the Honorary Treasurers, Professor Edward Hamilton, 120, Stephen's-green, and Dr. Thomas Purcell, 71, Harcourt-street, Dublin. The committee, having decided to immediately publish the list of subscribers, adjourned for a week.

EDINBURGH.

(From our own Correspondent.)

ROYAL SOCIETY OF EDINBURGH.

AT the ordinary meeting held last week, Sir Willia Thomson, the newly-elected President, took his seat. H subsequently made two communications to the Socie upon wave motion, producing formulæ which express t relation of the velocity of propagation to the wave-leng in cases where a stone is thrown into still water; and calculation of the total disturbance, and its compone elements, in the case of a ship gliding through a perfect smooth tract of water.

UNIVERSITY LIBRARIANSHIP.

The Senatus Academicus of the University have ma an appointment fraught with most important issues regards its general status as a centre of learning. Throu the death of the late Dr. John Small, the custodianship of t 200,000 volumes, constituting the library, had becon vacant, and the Senatus have made a very good use their patronage in appointing Mr. Hugh A. Webst to the office. There were over seventy applicants for t post. Mr. Webster is a graduate of Edinburgh, and has wide knowledge of books and of general literature. F twelve years he has worked on the staff of the "Encycl pædia Britannica," and has contributed articles on ver varied subjects of general interest to that publication amongst them articles upon Epigrams, Antiquities, Hamle the Indian Archipelago, Mermaids, and Fortunatus. He h also contributed geological, botanical, zoological, ethn graphical, and statistical accounts of various geographic areas to the same work, which are of high merit. H thorough knowledge of modern languages is also great importance, since it will enable him to suppl the marked deficiencies of the library in moder treatises and periodicals, especially in the department of natural science and medicine. In addition to ac quiring new treatises his duties in regard to those alread collected will not be slight, since there is at present no com plete catalogue of the library available for the genera public, a state of things which exists in no other collectio of equal importance in Europe. If Mr. Webster succeeds, a he doubtless will, in rectifying this deficiency, he will confe a lasting benefit on his *alma mater*, and will greatly lighte the task of those who seek knowledge in the volumes o her rich though pathless collection.

DRINKING FOUNTAINS FOR STUDENTS.

An elaborate drinking-fountain for the use of student was recently erected in the upper quadrangle of th New University Buildings, the gift of Mr. John Hope of Edinburgh; and following closely upon this presentatio another fountain has been added to the attractions of th Quadrangle at the College Buildings in South Bridge-street The latter is the gift of Dr. W. F. Cumming. It was publicl inaugurated by the Principal, Sir William Muir, and th members of the Senatus, last week, in the presence of numerous gathering, amongst whom were Dr. Cumming the donor, Mr. Sydney Mitchell, the well-known Scottis architect, who furnished the design, and his father, Dr Arthur Mitchell, C.B.

STUDENTS AND PROFESSIONAL EXAMINATIONS.

At a recent meeting of the Students' Representative Council, the subjects of professional examinations in medicine, and the compulsory attendance of certain lectures were under discussion. The outcome of their deliberations were a series of resolutions, which were respectfully submitted to the University Court, in favour of permitting medical students to enter for the first part (anatomy and physiology) of the second professional, or intermediate, examination at the end of the second year of study, instead of at the end of the third, as now obtains. The Council also prays the Court not to sanction any further addition to the number of compulsory courses in the medical curriculum, while its conditions are as they are. Both these requests are justified by the present state of medical study in the University, where course after course of lectures or demonstrations has been added to the list of classes, attendance upon which is compulsory, without any corresponding

Digitized by Google

extension of the curriculum in respect to time. The consequence of this is overpressure in the case of very many of the students, and a sense of oppression in those who are not actually overworked, which it would be well if the authorities could see their way to mitigate in the way requested, or in other ways which might suggest themselves.

ROYAL HOSPITAL FOR SICK CHILDREN.

The Directors of the Royal Hospital for Sick Children have appointed Dr. Melville Dunlop to the post of extra-physician upon the staff of the hospital, vacant through the resignation of Dr. Hodsdon.

Edinburgh, Dec. 28th, 1886.

ABERDEEN.

(From our own Correspondent.)

ROYAL INFIRMARY.

The quarterly court of the managers of the Royal Infirmary was held on Monday, Dec. 13th, when it was resolved, on the motion of the president, Lord Provost Henderson, to make an appeal to the public for the funds necessary to carry out the proposed improvement and extension of the infirmary buildings. It was left to the committee of management to select a large committee thoroughly representative of town and country, who would take the matter in hand, and it was hoped that an endeavour would be made to have the sum, £24,000, subscribed before June 20th, 1887. There is little doubt as to the success of this scheme of the Lord Provost to celebrate the Queen's Jubilee. He himself has subscribed £1000, and a subscription of £500 has also been intimated. Two vacancies in the medical staff had to be filled up at this meeting, and a large number of managers attended to bestow their patronage. For the office of ophthalmic surgeon, rendered vacant by the lamented death of Dr. Dyce Davidson, Dr. MacKenzie Davidson was the only candidate, and he was appointed unanimously. When Dr. Blaikie Smith was appointed assistant physician he resigned the office of chloroformist, which he had held for eleven years, and Drs. Booth, MacGregor, and Ruxton were candidates for the appointment. The first vote gave the following result: Dr. Booth, 83; Dr. MacGregor, 78; Dr. Ruxton, 16. A second vote was then taken as between Dr. Booth and Dr. MacGregor, when the former was elected by a majority of four votes.

THE UNIVERSITY COURT.

A meeting of the Aberdeen University Court was held on Saturday, Dec. 18th, when there was laid before the meeting a communication from the Senatus, stating that at a meeting held on the 11th, the Senatus resolved to represent to the Court their desire to withdraw the proposals as to changes in the examinations in medicine. The court granted consent, and this, for the present at any rate, gets rid of the difficulties raised by Prof. Struthers' dissent and Prof. Ogston's threatened action.

THE TRAINING OF PROBATIONER NURSES.

Two or three months ago the late Dr. Dyce Davidson and Dr. Garden were appointed a subcommittee of the medical committee to make inquiries as to the training of probationers in other hospitals, and as a result of their inquiries they submitted a report upon the subject, and their suggestions have so far been acted upon. The report says that probationers ought to be engaged for two years, during which time they ought to receive a regular course of instruction both theoretical and practical. The theoretical part of their instruction is to consist of lectures, which are to be divided into three courses: first, a series of lectures by the lady superintendent on nursing, the economy of the sick-room, instructions as to the preparation of food for the sick, &c.; second, lectures by one of the surgical staff on elementary anatomy, with lessons on surgical nursing, including bandaging, description and preparation of instruments, dressings, &c.; third, a course of instruction by one of the medical staff on elementary physiology and medical nursing. The practical or ward training is to be given by the ward sisters, supervised by the lady superintendent and teachers who supply the theoretical teaching. Drs. Bruce and Garden have been appointed with Miss Lumsden to give the different lectures.

THE HEALTH OF THE CITY.

In October there was a decided decrease in the number of cases of scarlet fever, but it has again begun to spread, and the report for last month shows a large increase. In October 78 cases of scarlet fever were reported, but during November there were 107. In the later month there were also 14 cases of typhoid fever, as against 4 cases in October. The death-rate for October was 17·28 per 1000, but last month it mounted up to 23·22 per 1000. Whooping-cough and measles are also prevalent, and many cases have proved fatal.

Dec., 1886.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

A MEETING of Convocation takes place on Dec. 30th, and consequently will be held too late for me to record this week the result of the election for a Member of the Senate. One of the candidates (Major Fitzgerald) has withdrawn, and the contest will lie between Professor O'Sullivan, Mr. O'Connor, and Dr. McMordie. I have already given my opinion that the first-named gentleman will probably be elected, and therefore shall not refer further to this subject. At the meeting this week, several notices of motion have been given, the principal being as follows:—Dr. Knight will move that the Senate be requested to consider what precautions can be taken to ensure that only the votes of members of Convocation are recorded in senatorial elections. Dr. Thompson will move a resolution requiring that at elections of a Senator by Convocation each voter shall affix his name to his voting paper in presence of a justice of the peace or a clergyman, who also shall sign his name as witness. The recent rules adopted by the Senate for the medical curriculum of the University have created considerable dissatisfaction, and it is gratifying to learn that Professor Pye has a notice relative to this matter, in which he will call attention to it, and move, that in the opinion of Convocation it should be repealed, and rules framed for the guidance of medical students in accordance with the direction of the General Medical Council be adopted. The proceedings are expected to prove very animated, and it is to be hoped that the Chairman will exercise the powers entrusted to him in repressing all unseemly attempts at disturbance.

THE EPIDEMIC OF ENTERIC FEVER IN CORK.

The Public Health Committee will this week have under their consideration a very important report, prepared by an inspector of the Local Government Board (Dr. O'Farrell), which deals with the present sanitary condition of the city of Cork. Additional interest must be attached to the communication in view of the epidemic of enteric fever which has prevailed for some time past. Cork is supplied with water from the river Lee, taken about a mile above the city. A filtering tunnel has been erected, but sufficient precautions are not adopted to prevent contamination from the houses and towns and villages situated on the banks of the river from its source to the point of intake at the water-works. The physical features of the site on which Cork is built render it extremely difficult to drain the hills, causing steps and abrupt gradients, while the flat of the city is below high water of spring tides. The rubble sewers in the older parts of Cork are defective in every respect—rat-eaten and blocked, so that they are no better than elongated cesspools, saturating the porous alluvial soil, which surround them with organic matter, and throwing back foul sewer air on the higher levels, thus producing zymotic diseases in those parts of the city which ought to be most healthy. There are about 1700 tenement houses in Cork, and many of them, especially in the centre of the city, are old and structurally bad. The public cleansing of the streets is carried out in a most unsatisfactory manner; this is partly due to the want of funds, the soft character of the limestone used for repairing roads, and to the large rainfall. The want of a public abattoir and the condition of the private slaughter yards must exercise an injurious influence on the health of the citizens. Dr. Donovan, the medical officer of health, is inclined to attribute the prevalence of typhoid fever to the cleansing of old drains and the dispersion of their contents over the surface of the public park and other places of public resort. Dr. O'Farrell

Digitized by Google

thinks these views very probably to be correct, and that the present outbreak is due to the faulty condition of the sewers and to the effluvia arising from them and from a soil saturated with organic matter and specific germs, acting at a time when in many parts of the United Kingdom there would seem to be an "epidemic tendency" to the development of enteric fever. These are the chief points referred to in Dr. O'Farrell's report, and in addition he makes the following suggestions for the consideration of the Public Health Committee:—1. That street cleansing be improved, and that a complete system of domestic scavenging be undertaken by the Corporation. 2. That the sewers of the city be completed and modernised, and that a map of the city be provided, in accordance with the 23rd section of the Public Health Act. That all main sewers be ventilated at their highest levels, and that they be provided with side entrances, manholes, and not less than twenty ventilators for each mile of sewer. 3. That lodging-house and tenement yards and premises be kept in proper sanitary condition, and that the bye-laws made under the 41st, 91st, and 100th sections of the Public Health Act be strictly enforced. 4. That a public abattoir be erected on a suitable site, such as the old Passage Railway, with proper appliances for drainage, ventilation, and cleanliness. 5. That the sewage matter removed from drains and deposited in the Park, and elsewhere, be thoroughly disinfected; and, in future, that all scavenged materials be immediately removed from the city by water carriage, or else that they be deposited and disinfected in suitably placed and properly constructed manure depôts. 6. That the water-supply of the city be protected, as far as possible, from contamination by the means already suggested in this report. 7. That the Medical Superintendent Officer of Health should devote his whole time to the duties of his office.

Dublin, Dec. 27th, 1886.

PARIS.

(From our own Correspondent.)

EXPERIMENTS WITH THE VIRUS OF RABIES.

The most important news of the week comes to us from Vienna in the account of Professor von Frich's experiments with the virus of rabies supplied to him for that purpose by Monsieur Pasteur. M. von Frich finds: 1. That in animals which have died from rabies the virus exists in its most concentrated form in the central nervous system. 2. That small quantities of the cerebro-spinal substance of animals which have died from rabies injected under the dura mater by trephining are sure to be followed after a latent period of from fourteen to twenty-one days by the same disease, and this may be transmitted from these to other animals. 3. That the same disease, with the same symptoms and the same period of incubation, may be induced by intra-cranial inoculation with particles of medulla from human beings who have died of rabies, showing the identity in man and in the lower animals. 4. That infection is less sure by the subcutaneous method, and the period of incubation longer than with intra-cranial inoculation. 5. The length of the period of incubation depends upon the quantity of virus injected under the skin; the less the virus, the longer the incubation. 6. By the continuous intra-cranial transmission of the virus taken from the cerebro-spinal substance of rabbits, after a series of generations the period of incubation is shortened and its invasion is irregular. Later on the incubation still decreases, but the invasion becomes regular. 7. The *fixed virus* of an incubation period of seven days, which M. Pasteur obtains by inoculation from rabbit to rabbit through forty or fifty generations exceeds in intensity the virus of *street rabies*, not only in that the invasion of the disease is earlier, but also because the animals die without exception as well after subcutaneous injection as with inoculation of the dura mater. 8. The fixed virus does not seem to acquire by further transmissions any noteworthy shortening of its period of incubation. Sometimes the disease begins after six days; but, on the other hand, it may extend to eight, ten, or even twelve days. An incubation period of from eight to twelve days, and consequently a virulence of the same intensity as that of the fixed virus, may also be obtained by the transmission of street rabies, and this sometimes at the second or third generation. 9. M. Pasteur's method of obtaining a fixed virus of seven days' incubation is, perhaps, not the only one, for the said virus may sometimes be obtained much earlier, independently of the transmissions, and this virus is constant in its effects and in its period of incubation. 10. The virulence of particles of medulla diminishes daily under desiccation at 20° Centigrade over caustic potash, and is entirely destroyed after from fourteen to sixteen days. 11. Animals which have been subjected to hypodermic injections of a series of virus attenuated by desiccation become refractory to the stronger virus by the previous inoculations with the weaker virus if the stronger virus have not been used in too rapid succession. 12. Animals which have been inoculated hypodermically during ten days with virus of progressive virulence (medulla from ten days to one day) have not been refractory to infection with the fresh virus of street rabies, and have only exceptionally escaped after intra-cranial infection. 13. Rabbits and dogs inoculated by trephining with the virus of street rabies of sixteen days' incubation have always succumbed, notwithstanding the preventive treatment already described. 14. M. Pasteur attributed to the method of slow vaccinations the unsatisfactory results obtained previously by M. von Frich, and recommended a more intensive mode of treatment. The experiments carried out conformably to M. Pasteur's instructions have given no more favourable result; all the animals died of rabies. 15. The experiments have demonstrated a most important fact—that is, that in the rapid process the weaker preservative medullæ do not confer the same certainty of immunity from the effects of inoculation with the stronger medullæ. Of a series of dogs and rabbits inoculated as a control-experiment to that described in the preceding paragraph, and in which the rapid process was carried out without previous infection, most of the animals died of rabies. 16. Most of the animals which were submitted to the preventive treatment after subcutaneous inoculation with street rabies, died of the disease even when the period of incubation was thirty-four days. These experiments show, says M. von Frich, that Pasteur's method of rendering animals refractory to rabies is not yet either sure or certain. There is not yet a sufficient scientific basis for the application in man of a preventive treatment after the bite of a rabid animal. It is, moreover, quite possible that the preventive treatment, at any rate the intensive method recently recommended by M. Pasteur, may itself transmit the disease.

A PATHOGNOMONIC SIGN OF CANCER OF THE STOMACH.

A patient was shown at the last meeting of the Société Médicale des Hôpitaux who exemplifies the condition said by German writers to be characteristic of cancer of the stomach, a condition found by M. Debove to be constant in such cases, and which he proposes as a pathognomonic sign of the disease. In malignant disease of the stomach it will be found that hydrochloric acid is always wanting, whereas it lasts constantly during digestion in every other case. In M. Debove's patient this absence of hydrochloric acid enabled a diagnosis to be made at a period when there was no other symptom of cancer, and the disease was looked upon as dyspepsia, an opinion shared by M. Debove himself until he had ascertained the composition of the gastric juice. Since the beginning of the year the man has been under observation, and the real nature of his disease now constituted by a characteristic tumour the size of an egg, is no longer doubtful. In reply to questions M. Debove said that he obtained the liquid for examination by means of the œsophageal tube, and that the test used for distinguishing the acids were those recommended by the Germans. A solution of gentian violet (1 in 5000) gives a blue coloration with HCl. "l'orange Poirier" in saturated solution gives a red reaction with the same acid. Lactic acid is recognised by the increased yellowing of perchloride of iron, and by change in colour of a mixture of perchloride of iron and carbolic acid, from amethyst blue to yellow.

TREATMENT OF EPILEPSY.

M. Dujardin-Beaumetz is using antifebrine extensively in the treatment of epilepsy. As far as I know nothing has as yet been published on the subject, but I am told that in antifebrine we possess one of the most powerful "moderators" of the spinal centres.

THE CLIMATE OF HYÈRES.

(From our Special Correspondent.)

AMONG the health-resorts of the Riviera, Hyères holds its own for its climatic advantages. While Cannes was but a miserable fishing village, and Mentone and Nice almost unknown, French doctors sent their patients to Hyères, and it was the first town on the Riviera where experiments were made in the climatic treatment of disease. It has the double advantage of being more to the south that any of the other towns on this line, and yet it is the nearest to London and Paris. Dr. W. P. Biden, the resident English physician, has favoured us with the meteorological observations he has made during the last six winters. His Sheringdon screen or box is well exposed to the north in the garden of the Hôtel des Isles d'Or. There are no plants near to afford shelter, and having visited the spot I can testify that the observations are taken in the fairest possible manner. The record of the results acquired will be seen in Table I. The climatic advantages, as demonstrated by these statistics, are further set forth by a comparison with other health-resorts. (See Table II.) The statistics in this table are open to question so far as the San Remo record of the number of days on which rain fell is concerned. As the amount of rain which fell was in excess of the other Riviera stations, probably those days when the showers were very slight were not included in the calculation. It will be seen that Hyères is at once warmer and yet colder than the other Riviera resorts mentioned. This implies that greater care must be taken at night, and then the invalid will derive all the profit of the higher day temperature and the higher mean temperature. For all practical purposes this is just the advantage required. In conclusion, it may incidentally be mentioned, that the great storms of Dec. 8th and 9th had altogether lost their fury when they reached Hyères. The weather has, on the whole, remained fine throughout this trying period.

December 11th.

TABLE I.—*Six Months of the Winter Season at Hyères during the Years 1879 to 1885.*

	November.	December.	January.	February.	March.	April.	Means.

Obituary.

ALFRED WILTSHIRE M.D., F.R.C.P.

THE loss sustained by the early death of Dr. Wiltshire—a loss scarcely less felt in the world of science than by his friends and family—cannot be passed by without record.

Alfred Wiltshire was a native of Gloucester. Members of his family had been yeomen in that county and in Worcestershire. He received his early education at a private school. His medical studies were pursued at University College in London. The *res angusta* perhaps frustrated his desire to graduate at the University of London. The loss of so earnest and capable a member is but one of many examples of the injury suffered by the London schools through the narrow and exclusive policy of this University. Like many other men distinguished as successful students, he found it desirable to seek superfluous attestation of the theoretical knowledge and clinical skill acquired in London by going to Scotland for a university degree. He was enrolled M.D. at St. Andrews in 1862.

In the following year he passed the more real, but less honorific, examination for the licence of the Royal College of Physicians. Thus equipped, he started in the north of London as a general practitioner, fought bravely the battle of life, urged by the consciousness of being fitted for a higher position, and resolute to achieve it. His first step upwards was made when he was appointed a medical inspector of the Privy Council. This position helped him materially on the road towards the goal to which his ambition pointed. In it he did good work in the cause of vaccination. He next took the bold step of entering in the competition for consulting practice. So he took the Membership of the Royal College of Physicians in 1868, and when he had made his mark he was elected a Fellow in 1878. Fairly launched on his new career, and working hard in scientific pursuits, he was made treasurer of the Medical Society. He rendered valuable service in the administration and reorganisation of that Society, and was appointed to give the Lettsomian Lectures in 1877.

The bent given to his studies by his opportunities, rather than perhaps by his inclination, led him to cultivate obstetrics more especially. But he was accomplished as a general physician, and became distinguished as a surgeon. He joined the Obstetrical Society in 1866, was made librarian in 1871, secretary in 1874, and vice-president in 1877. He contributed five papers to the Transactions of this Society, all marked by the qualities of keen observation, earnest study, and judicious deduction. Amongst the most valuable of these is the memoir on "Tetanus after Abortion," written in 1872. Amongst less formal communications two are more especially interesting. In vol. xx. for 1878, Dr. Wiltshire referred in discussion to the "normal asymmetry" of the

Digitized by Google

child's head at birth, and to the blue colour of the eyes as a constant condition. He had originally described this phenomenon in THE LANCET in 1871. He said that, from information received from physicians practising amongst negroes, every black child was born with blue eyes.

Diagnostic skill and surgical enterprise have seldom been more strikingly exhibited than in an operation which made him famous amongst ovariotomists. In the nineteenth volume of the "Transactions of the Pathological Society, 1868," is recorded the history of a case of "A large multilocular ovarian cyst removed by operation from a patient with acute peritonitis." His merit in the initiation of this practice of looking upon collapse and peritonitis from bursting or other injury of the tumour as a reason for prompt action rather than for regarding the case as beyond hope, has received just recognition from Olshausen in his work on "Diseases of the Ovaries." This distinguished authority says: "Wiltshire appears to have been the first who had the courage to operate during collapse caused by torsion of the pedicle." It is given to few men to deserve the triple praise due to pathological sagacity, surgical boldness, and originality.

In 1883, when the first blow had already been struck at his health, he published a series of lectures on the "Comparative Physiology of Menstruation." He was always given to visiting the Zoological Gardens, and he turned to account the opportunities there afforded to study the habits and physiology of the animals. The knowledge so acquired was extended by observations made in the country, to which his shattered health often compelled him to retreat. These lectures constitute the most original and instructive accession to our knowledge of menstruation—a function which lies at the foundation of gynæcology—that has appeared in this generation. We cannot in this place attempt an adequate analysis of it. The leading theme is to illustrate and accentuate the general law insisted upon by Darwin, that Periodicity rules alike over the physical, animal, and vegetable worlds.

Dr. Wiltshire held various public appointments. First he became attached to the St. Mary's Hospital School as assistant-physician, and subsequently he was made physician to the out-patients and joint lecturer on obstetrics with Dr. Meadows. He was physician for diseases of women to the West London Hospital, and was for a short time physician to the Samaritan Hospital. He also held the post of physician to the British Lying-in Hospital. About four years ago symptoms of locomotor ataxy appeared. The significance of these symptoms became plain to his colleagues and immediate friends, although, with the hopefulness and tenacity of a sanguine nature, he battled against the enemy, refusing to yield. And more than once his resolution seemed to have conquered. But the remissions inspired little confidence in anyone but himself, and at last body and mind gave way. In the summer of 1885 he resigned his appointments and the hope of resuming practice. He had married a daughter of the late Mr. Albert C. Waterlow, thus becoming the brother-in-law of Dr. Ferrier. His widow and two sons survive him.

De mortuis nil nisi bonum. We need not hesitate at the qualification: *nisi verum.* What is true of him is mostly good. He had a warm heart for his friends. If he at times exhibited some jealousy, tinged even with bitterness towards those who he thought opposed his progress, the failing will be explained and pardoned by the reflection that it is not uncommon in men who have been forced to struggle hard in early life; and who, in their impatience to succeed, are apt to be irritated by opposition which they feel is undeserved. And those who knew him best would trace not a little of his asperity to the disease which was insidiously sapping his nervous centres. At any rate, Alfred Wiltshire leaves behind him sterling work enough that will endure, bearing no trace of ungenerous feeling.

THOMAS WALKER, M.D., J.P.

DR. THOMAS WALKER, who died at Peterborough on the 16th inst., was born in Dumfriesshire in September, 1796, and was therefore in his ninety-first year. He had been for seventy-one years a qualified member of the medical profession, having become a licentiate of the Edinburgh College of Surgeons in 1815. At the time of his death he was the oldest licentiate of that College, and also father of the Faculty of Physicians and Surgeons of Glasgow. The oldest son of the late Josiah Walker, M.A., Professor of Humanity (Latin) in the University of Glasgow, Dr. Walker was descended from a long line of ministers eminent in the Scotch Church, his ancestor in the seventh generation being that most celebrated of sixteenth century Scotchmen, the great reformer, John Knox. In stature tall, square-built, muscular, with a countenance expressive of strong individuality, endowed with abilities far above the average, courteous, honourable, and just to everyone, he was physically, intellectually, and morally a notable man. Most hospitable, highly educated, of refined tastes, his mind stored with accurate and widely-ranging information, his society and friendship were at all times highly valued by those of all classes and ages with whom he was brought in contact. He was especially fond of associating with men younger than himself, and, as was remarked by us of him in our memoir of his pupil, the late Dr. Harry Leach, he was "a physician who had been peculiarly fortunate in the number of honoured and successful men trained by him for the profession." Although Dr. Walker was, in his own town and district generally, universally esteemed and regarded with strong personal affection, it was given perhaps to only a privileged few to know the almost feminine tenderness of heart which lay beneath the somewhat austere exterior.

Dr. Walker studied in Edinburgh, and qualified at the earliest possible date with a view to entering at once on active medical service in the army; but the battle of Waterloo and the subsequent general peace defeating this ambition, he went to Paris, and there, under Roux, Dupuytren, Dubois, Larrey, and other eminent surgeons (of whom he wrote in letters still extant life-like descriptions), continued his medical studies. On his return from the Continent he became house-surgeon to the Westminster Hospital, and at the same time attended the School of Medicine in Great Windmill-street. Thus specially qualified for the practice and teaching of surgery, Mr. Walker returned to Glasgow, intending to become a candidate for the Chair of Surgery which was shortly to become vacant. The success of his candidature was considered certain, but an attractive offer of a practice at Peterborough induced him to change his plans. He commenced practice at Peterborough in 1819, and the Chair of Surgery, on becoming vacant, was filled by his most intimate friend, Professor James Laurie. Mr. Walker speedily acquired the confidence alike of his medical brethren and the public, and was appointed the first surgeon to the Peterborough Infirmary—an office which he held for forty-three years.

In 1843, Mr. Walker added to his other qualifications that of M.D. of Edinburgh. Dr. Walker was a most successful surgeon, and although he himself wrote but little, the first hints of many a step in modern surgery are to be found in the note-books of the young men who were from time to time either his private pupils or house-surgeons to the Peterborough Infirmary. In his operations, as in all else he did, there was an utter absence of attempt at display. Thorough anatomical knowledge, a skilful hand, a clear judgment, and a cool temperament ensured success. He was an excellent lithotomist, and operated eighteen times successfully before losing a case. Fond of mechanics, and himself a practical adept, he continually devised new surgical appliances and methods of treatment. As a physician Dr. Walker was no less successful than as a surgeon, early discarding the indiscriminate and empirical use of remedies. He continued in full practice until the year 1876, when a severe illness laid him aside for some months, and he never resumed active work. He was a Justice of the Peace for the Peterborough division of the County of Northampton, and for some forty years served as an active and efficient magistrate, filling also various public offices, until partial deafness made him doubt his own capacity for business. He leaves fifty-five direct descendants, of whom two sons and a grandson are members of the profession. An early riser, temperate in his habits, taking pleasure in strong physical exercise, he occupied his leisure in gardening, carpentering, and drawing. He was a great reader, and retained his vigour of intellect and body almost to the last. When in his eightieth year, he, with his friend Mr. O'Connor of March, Cambs., went at night on foot across a fen drove and fields too bad for wheels, and in a cottage by the light of a tallow candle performed herniotomy.

The funeral took place on the 21st inst. at Peterborough, amid every sign of respect from the inhabitants.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a recent meeting of the Court of Examiners, the following was admitted a Fellow of the College:—

Joseph Byrne.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Dec. 23rd:—

Barton, G. A. Heston, Wenlock House, Burton-road, Kilburn.
Bidwell, Leonard Arthur, Lee-terrace, Blackheath.
Blenkinsop, Alfred Percy, Hilldrop-crescent, N.
Carvalho, Alberto Pedro de, M.R.C.S., Lidlington-place, Ampthill-square.
Fox, Geo. Martin, Oxford-street, Bilston, Staffordshire.
Harris, Edward Bernard, Alkham-road, Stoke Newington.
Housley, Philip Henry, Colebrooke-road.
Phillips, Thomas, Newcastle Emlyn, South Wales.
Slater, William Arnison, Green-lanes.
Vidler, Albert Edward, Magdala House, Rye, Sussex.

Passed on the 30th ult.:—

Cook, Edward Thomas, M.R.C.S., Southsea.
Jong, Edward Meyer de, Blackpool.
Walls, James, Wigan.

SCARLET fever is reported to be spreading rapidly in the locality of Treharris.

A LEGACY of £200, free of duty, left to the Leeds Infirmary by the late Mr. William Neal, has recently been paid over to the treasurer of that institution.

THE QUEEN'S JUBILEE is to be recognised at Bristol by the founding of a Maternity Hospital, and at Folkestone by the erection of a public hospital.

MEATH HOSPITAL, DUBLIN.—It has been determined by the governors to build a special ward, to be called the "John Barber Ward," as a token of appreciation of the late Mr. Barber's generosity.

ON the 21st ult. a property owner at Ramsgate was summoned for neglecting to connect his property with the sewers. The magistrates ordered the nuisance to be abated.

A ROMAN Catholic Home for Female Inebriates was formally opened at Hammersmith on the 21st ult., the premises recently occupied at Kilburn having proved unsuitable.

AN inquest was held at Sutton Coldfield on the 23rd ult., on the body of Mr. Charles Barlow, surgeon, whose death occurred suddenly on the 21st. Medical evidence having been given to the effect that death had resulted from syncope, the jury returned a verdict accordingly.

KILMARNOCK FEVER HOSPITAL AND INFIRMARY.—The annual meeting of the subscribers to this institution was held on the 16th ult. The annual report showed an income for the year of £1521 and an expenditure of £1528, which, with the deficit of previous year, left a balance due to the bank of £349. The invested capital amounts to £5605.

AT a meeting of the Board of Management of the Manchester Royal Infirmary on the 23th ult., it was resolved that one of the wards of the Institution be named the "Thomas Rose Ward," to perpetuate the name of Alderman T. Rose, from whom the hospital recently received a munificent legacy.

PROSECUTION UNDER THE FOOD AND DRUGS ACT.—At the Dale-street Police-court, Liverpool, last week two grocers were fined each 10s. and costs for selling adulterated pepper. The foreign ingredient—a mixture termed "poivrette," which was found in one case to the amount of 65 per cent., and in the other to 55 per cent.—appeared to consist of ground nutshells and olive-stones.

AT the Greenock Police-court, on the 18th ult., a lodging-house keeper was fined 10s., with the option of going to prison for seven days, for neglecting to report to the sanitary inspector the presence on her premises of a child who was suffering from enteric fever, although she had been warned to do so by a medical man.

"THE VALUE OF ANALYSIS."—Dr. Thomas Stevenson has sent in his resignation of the office of analyst for Bedfordshire in consequence of the Town Council having tacitly declined to take any further action in respect of the late dispute regarding the analysis of a sample of beer. The resignation has been accepted.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

DUNLOP, G. H. MELVILLE, M.D., M.R.C.P.E., has been elected an Extra Physician to the Royal Edinburgh Hospital for Sick Children.

DUTT, A. C., B.A.Cantab., L.S.A., has been appointed Resident Medical Officer to the Morpeth Dispensary.

DOUTY, JOEL HARRINGTON, M.R.C.S. (late Senior Assistant Medical Officer to the Worcester County Asylum), has been appointed Medical Superintendent of the Berks County Asylum, vice R. B. Gilland, M.D., resigned.

HOVELL, DENNIS DE BERDT, F.R.C.S.E., has been appointed Consulting Surgeon to the London Orphan Asylum, Watford, Herts.

HUDSON, LEOPOLD, M.R.C.S., L.R.C.P. Lond., has been appointed Pathologist and Curator of the Museum to the Middlesex Hospital.

HURLBUTT, SPENCER, M.R.C.S., L.R.C.P.Lond., L.S.A., has been appointed Assistant Medical Superintendent and Dispenser to the Fulham Union Infirmary, Hammersmith, W., vice H. Bamber, M.B., C.M., resigned.

LLOYD, JOHN JENKIN, L.R.C.P., &c., has been appointed Medical Officer to the Prince of Wales Lodge of Oddfellows, Llanelly.

LOCKE, GEORGE, M.R.C.S., L.R.C.P.Ed., L.S.A., has been appointed Medical Officer to the Dalston and Haggerstone Branch of the Metropolitan Provident Medical Association, vice Towne, resigned.

MORGAN, WILLIAM PRINGLE, B.A., M.B., B.Ch. Univ. Dub., has been appointed Medical Officer and Public Vaccinator to the Seaford District of the Eastbourne Union, vice Buckmaster J. Tuck, M.R.C.S., L.S.A., J.P., deceased.

PEARSON, RICHARD, M.R.C.S., L.R.C.P.Lond., has been appointed Junior Assistant House-Surgeon to the Hull Royal Infirmary.

PRAEGER, B. A., L.F.P. & S.Glas., L.S.A., has been appointed Surgeon to the Vancouver Coal Company's Collieries at Nanaimo, British Columbia.

Births, Marriages, and Deaths.

BIRTHS.

CARTER.—On the 24th ult., at Dilkusha, Lucknow, the wife of Surgeon-Major Sidney H. Carter, M.B., Army Medical Staff, of a daughter.

MACLEHOSE.—On the 17th ult., at The Croft, Sevenoaks, the wife of Norman M. MacLehose, M.B., of a son.

MEYERS.—On Nov. 16th, at Rushworth, Victoria, Australia, the wife of Herbert Henry Meyers, M.R.C.S., L.R.C.P., of a son.

PIGEON.—On the 26th ult., at 6, Albion-street, Hull, the wife of Henry W. Pigeon, M.A., M.B., B.C., F.R.C.S., of a son.

PLATT.—On the 15th ult., at St. James's Lodge, West Hampstead, the wife of William H. Platt, L.R.C.P.Ed., L.R.C.S.I., of a daughter.

MARRIAGES.

HUNTINGTON — BOWLES. — On the 15th ult., at St. Mary's, West Kensington, William Huntington, M.R.C.S., L.R.C.P.Lond., to Charlotte MacLeod, daughter of Joseph Bowles, Esq., late of Sydenham.

MERCES—ROW.—On the 15th ult., at the Parish Church, Stoke Damerel, by the Rev. W. H. Allin, James Merces, M.R.C.S., L.R.C.P.Lond., of Drayton-park, Highbury, to Florence Everard, seventh daughter of the late Fred. Row, M.D., J.P., of Devonport.

MORTON—HALL.—On the 16th ult., at St. Paul's Church, Edinburgh, John Morton, M.D., L.R.C.S., L.R.C.P., to Agnes, only daughter of the late John Hall, Esq., of Birmingham.

MURRAY—MATHESON.—On the 29th ult., at 25, Abercromby-place, Edinburgh, by the Rev. Alexander Whyte, D.D., Free St. George's Church Edinburgh, assisted by the Rev. Donald Murray, Free Church Tarbat, Ross-shire, father of the bridegroom, Donald Roderick Murray, M.B., C.M., Admiralty Surgeon and Agent, Leith, to Johanna (Bunty), daughter of the late Robert Matheson, Esq., of H.M. Board of Works, Edinburgh.

REEKS—THORNTON.—On the 23rd ult., at the Cathedral of the Holy Trinity, Gibraltar, by the Ven. Archdeacon Govett, assisted by the Rev. D. Nickerson, Chaplain to the Forces, John Reeks, M.R.C.S.E., &c., of Forest-gate, Essex, to Mary Rosa, elder daughter of Henry Thornton, Esq., of Ashtead Cottage, Gibraltar.

DEATHS.

BELL.—On the 14th ult., at his residence, Merlin, Eastbourne, William Bell, M.D., L.R.C.S.I., in his 83rd year.

DICKINSON.—On the 27th ult., at 162, Bedford-street, Liverpool, Annie, the beloved wife of Edward H. Dickinson, M.A.Oxon., M.D.

GREAVES. — On the 10th ult., at Burton-on-Trent, George Greaves, L.S.A., in his 83nd year.

GROVER. — On Christmas Day, suddenly, at St. Anne's, Lewes, John Pollington Grover, M.R.C.P.Ed., M.R.C.S., L.S.A., aged 38.

NANKIVELL.—On the 24th ult., at Ashley Lodge, Torquay, Chas. Benjamin Nankivell, M.D., aged 81.

TAYLOR.—On the 17th ult., at 5, Ashley-road, Bristol, Frank Taylor, M.R.C.S., L.S.A., late of Redcliff, Bristol, aged 30.

TRAILL.—On the 10th ult., at North-street, St. Andrew's, Fife, William Traill, M.D., of Woodwick, Orkney, aged 68.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 3.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. J. Langdon Down: On some of the Mental Affections of Childhood and Youth (Lettsomian Lecture).

Tuesday, January 4.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Chemistry of Light and Photography (adapted to a juvenile auditory).
SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—4 P.M. General Quarterly Meeting. Mr. Tudor Trevor: The prevailing Indifference to Inebriety.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Annual General Meeting for election of Officers and Council. Mr. Eve: Multiple Cavernous Angeiomata in Deformed Leg.—Dr. Griffith: Extra-uterine Fœtation.—Mr. Butlin: Melanotic Sarcoma of Breast.—Dr. Carrington: A case of Recovery from Tubercular Meningitis.—Dr. Wiglesworth: Peripheral Neuritis in Raynaud's Disease.—Dr. Bruce Clarke: Subperitoneal Rupture of Bladder. Card Specimens:—Mr. Targett: Congenital Deformity of Lip.—Mr. Eve: (1) Multiple Painful Lipomata of Arms; (2) Diffuse Unilateral Papilloma of Tongue.—Mr. Charters Symonds: Hydatid of the Breast.

Wednesday, January 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

Thursday, January 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Chemistry of Light and Photography (adapted to a juvenile auditory).
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. T. Morton: The Analogy between Croup and Asthma.—Dr. Goodhart: Cases of Peritonitis.—Dr. Blenkinsop: Some remarks on Cancer and its Treatment.

Friday, January 7.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Dr. Blenkinsop: Phthisis and its Treatment.—Dr. Seymour Taylor: The Etiology of Phthisis, and its Treatment from a Hygienic Standpoint.—Mr. Bruce Clarke: The Operative Treatment of Intercurrent Disease in Phthisical Patients.—Mr. H. Percy Dunn: Card Specimens of Pulmonary Tuberculosis.—Dr. P. S. Abraham: Specimens of the Tubercle Bacillus, and Microscopical Sections of Tubercular Organs in Man and the Lower Animals.—Messrs. Wright and Co.: An Exhibition of Oro-nasal Inhalers, Sprays, and Instruments.

Saturday, January 8.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Chemistry of Light and Photography (adapted to a juvenile auditory).

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

HEALTH OF THE UNITED STATES ARMY.

THE annual report of the Surgeon-General of the United States Army for 1885 shows that the American soldiers, like the greater part of the rest of the world, were unusually healthy during that period. The actual number of admissions to sick was 32,990, or 3839 less than for the preceding year. Compared with the average rate for ten years preceding, the admissions were about one-fifth less. A greater proportion of invalids was furnished by troops under thirty-one years of age, while up to the age of twenty-five the rate proved so much above the mean for the whole army that the Surgeon-General states it may be fairly questioned whether the services rendered by these young men are equal to the cost of their maintenance. Men of Irish birth furnished the highest mortality rate, or 7·9 per 1000; the English stood next, and the Germans third.

H. W. Verdon, M.D., and *W. Gibson Bott, L.R.C.P., M.R.C.S.*—Our correspondents' letter arrived too late for publication this week.

Mr. E. M. Harwood is thanked.

VACCINE LYMPH IN TROPICAL CLIMATES.

To the Editors of THE LANCET.

SIRS,—At the request of Bishop Smythies in E. Central Africa—lat. 4° to 15° S.—I would ask you to give me space in your columns to solicit information as to the best way of preserving and transmitting vaccine for use in that tropical climate. We send out quantities every month, and have tried various kinds, and also methods of storing. The mail is monthly only, and the voyage is twenty-eight days to the nearest port, with a fortnight further on the inland journey to our stations. Only quite a small percentage is any good on arrival. If any of our home authorities can help us to discover the right kind and method it will be a great boon, and of public advantage.

It may interest your readers to know that Archdeacon Foster, in lat. 5°, has lately vaccinated thousands by means of several assistants and one qualified medical man. He has kept a district round his stations free from small-pox, whilst the belt of the country just beyond is badly troubled with the disease. I will gladly give further information to any who care for it. I am, Sirs, yours faithfully,

The Universities' Mission to Central Africa, Delahay-st., S.W., Dec. 20th, 1886. WM. H. PENNEY.

*** If lymph has to be kept for a long period, it is best preserved in sterilised tubes, and should be stored in the icehouse of the vessel conveying it to its destination. The cultivation of vaccine lymph at the place where it will be used gives a better promise of success than its transmission from England.—ED. L.

THE MOST EXTENSIVELY QUOTED MEDICAL JOURNALS IN THE WORLD.

To the Editors of THE LANCET.

SIRS,—A short time ago I had the curiosity to count the number of extracts from foreign sources in some Russian journals which are remarkable for their copious and impartial *précis* writing from the medical journals of all other countries. The numbers were as follows:—THE LANCET, 12; *Brit. Med. Jour.*, 7; *La Semaine Méd.*, 7; *Deutsche Med. Zeit.*, 3; *Centralbl. für Chir.*, 3; *Med. Press*, 2; *Journ. of Cut. and Venr. Dis.*, 2; *La France Méd.*, 2; *Centralbl. f. Nervenheilk.*, 2. Besides these, there were single extracts from 1 English, 4 American, 1 Canadian, 6 French, 9 German, and 3 Italian medical journals. Again, I have just counted the quotations from non-Russian journals in the last four numbers of the *Vrach*, with the following results:—THE LANCET, 11; *Brit. Med. Jour.*, 7; *Münchener Medicin. Woch.*, 11; *Allgem. Med. Cent. Zeit.*, 8; *La Semaine Médicale*, 8; and a large number of other English, American, German, French, and Italian medical journals from 1 to 4 each. This all tends to show that though our English medical journals are less numerous than those of several other countries, our great weeklies are extensively read and appreciated abroad. *A propos* of weeklies, it is not, I suppose, generally known that there is in existence one (and one only, as far as I can learn) daily medical journal. I have before me a copy of *El Diario Médico-Farmaceutico*, published at Madrid; but I cannot say that I feel any longing for the time when it shall be instituted in England. There is more valuable and original matter in one number of THE LANCET than would probably be found in a whole year's issue of the *Diario*.

I am, Sirs, yours truly,

Woolwich, Dec. 22nd, 1886. THEODORE MAXWELL.

An Intending Candidate will find the information he desires in our last Students' Number, published in September, 1886.

THE RIDDELL FUND.

To the Editors of THE LANCET.

SIRS,—Will you kindly insert the enclosed list of subscriptions to the above fund, and oblige,

Yours truly,

Dec. 29th, 1886. J. WICKHAM BARNES.

H. (Oulwich).—Our correspondent will find sufficient information in a little work on Diabetes by Dr. Philpot, published about a year ago.

PERSISTENT DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—I recently had a case similar to the one described by your correspondent, "A. H.," in your last issue (p. 1209), but of so much more severe a type as to bring the patient in the course of two years into a condition of extreme prostration and emaciation. My patient—also a young lady—consulted me about six months ago, and she is now quite well. I prescribed the perchloride of iron in four-minim doses, and hydrochloric acid in ten-minim doses, after meals. The diet ordered was one of milk and farinaceous foods, at regular intervals of four hours only. When the diarrhœa had considerably abated and the patient was beginning to put on flesh, massage was used, on the recommendation of Dr. Whitehead of Manchester, with the effect of rapidly restoring the patient's flesh and strength.

I am, Sirs, your obedient servant,

Clapham-le-Moors, Dec. 22nd, 1886. C. R. ILLINGWORTH, M.D.

MATERNAL IMPRESSIONS.

To the Editors of THE LANCET.

SIRS,—Some difference of opinion exists in reference to the influence of maternal impressions on the formation of the fœtus in utero. The following case will at least show a reasonable *propter hoc*.

Mrs. [redacted], aged thirty-eight, was delivered of her first child minus one hand, the left forearm terminating at the wrist in a perfect stump. I questioned her directly after delivery as to any impression she may have received during pregnancy; but she could call none to mind. The morning, however, she remembered that two men presented themselves at the bar of an inn, of which she was then landlady, and showed her that [redacted] had lost a hand in some accident. At the time, she said, I gave her "quite a turn." She was then in about her second month of pregnancy. It is a curious coincidence, if nothing more.

I am, Sirs, yours obediently,

Dec. [redacted], 1886. J. G. BRADEN, M.R.C.S., L.S.A.

COMPLAINT AGAINST A PHYSICIAN IN JAMAICA.

A CORRESPONDENT writes reflecting on a medical practitioner for not responding to the call of a lady in her labour, on the ground that he was going to devote himself to black and brown women who appeared to appreciate him more. It is asserted that the physician in question was the family attendant, and that in consequence of his refusal, of which he had given no notice, the labour became protracted and complicated. We do not think that this can be a complete statement. It is incredible that a physician engaged to attend a lady in her confinement would make such a frivolous excuse for not doing so.

Mr. Clark Bell (New York).—It will always be impossible to define insanity, because it is a *negative* quality. Like disease, insanity simply means unsoundness. It is only in respect to special forms of disease or unsoundness there can be definitions.

M.D. Edin. will see by reference to our issues of Dec. 18th and 25th, pp. 1208, 1257, that the matter has been already noticed.

A PLAN OF CASE-MAKING.

To the Editors of THE LANCET.

SIRS,—Since entering into practice it has always been my wish to keep notes of every case treated; but I have found this very difficult to do, partly from want of time, and partly from want of a convenient method of taking and keeping the notes. After trying a great many plans I arranged, about a year ago, a case-sheet with convenient headings, and had a number printed. These I have used during the present year, and have found them very convenient. The cases being entered on loose sheets, it is easy to write them up at odd moments; the subdivisions make the writing of them more rapid, and the arrangement of them in portfolios renders reference to old cases easy. The sheets have the usual heading, with spaces for name, address, age, occupation, disease, result, date; also spaces for a letter and a number. The former is filled in with the initial of the surname, the latter with the number the case occupies amongst those of the same letter. Thus if the name is Smith, and it is the tenth case commencing with S, notes of which have been taken, the case-sheet is endorsed—Letter S, No. 10. On the first page, under the heading, are spaces for family history, personal history, present condition, and advice and treatment. The second page is occupied with progress of case, whilst the third and fourth pages are utilised either for diagrams, charts, or for any particulars which have to be given more fully than the first and second pages admit of. The sheets as filled are placed in a portfolio, which has separate compartments for each letter. Thus, if it is wanted to look up the case of Smith, it is only necessary to take the case-sheets out of compartment S. There are also compartments for unfilled case-sheets, blotting-pad, and diagrams and charts. The label outside the portfolio shows the period of time covered by the sheets within. I showed a specimen to Messrs. Daniellson and Co., London, and they have undertaken the publication of the case-sheets and portfolios.

I am, Sirs, yours faithfully,

December, 1886. E. MACDOWEL COSGRAVE, M.D.

CONSULTANTS.

To the Editors of THE LANCET.

SIRS,—Is it usual for a consultant in London to write a reply, direct a patient, advise and prescribe, asking and taking a guinea fee, when the patient is under the care of the ordinary family attendant, and when that gentleman has been in communication on several occasions with the said consultant in this particular case?

I am, Sirs, yours faithfully,

December, 1886. M.D.

*** The above action on the part of the consultant is not usual, and cannot be commended.—ED. L.

MEDICAL BURSARIES.

To the Editors of THE LANCET.

SIRS,—In your issue of Oct. 30th I see that some of our old graduates do not forget their *alma mater* even when far away. It is to be hoped that more will follow Dr. Gunning's example in founding bursaries for graduates of the University. There is only one thing that I, as an old university man, regret, and that is that the names of Syme and Spence were omitted in denominating the different bursaries. "Honour to whom honour is due," and no two men together ever did more, in my humble opinion, for clinical and practical teaching than those two.

I am, Sirs, yours faithfully,

Uniondale, Cape Colony. JOHN BROWN, M.B.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—I have been rather surprised at the seeming apathy of the London medical students with regard to the movement which has been, and is being, made in their favour. I refer, of course, to the scheme for granting degrees in place of the present double qualification. As the present movement concerns all London medical students, does it not seem strange that they have never held a meeting among themselves to pass resolutions which would serve to strengthen the hands of those agitating on their behalf.

I am, Sirs, yours truly,

Dec. 27th, 1886. STUDENT.

Digitized by Google

ACTION BY A MEDICAL MAN AGAINST AN INSPECTOR OF THE POOR AT KIRKWALL.

We are glad to see that the judge expressed his sense of the "technical, not to say harsh," way in which the Board of Birsay had treated their medical officer in terminating one engagement, without notice, to put him upon lower and less advantageous terms. The judge thought the board should pay their own expenses.

Mr. H. Anderson.—The observations which were made upon the Llandudno Cottage Hospital in our issue of Dec. 11th, 1886, were based upon the last report, issued that year, and also on a comparison between that and the one for the previous year.

G. P.—There is no invariable rule. It is better to follow the custom that has been in vogue in the locality.

T. P. R.—The question is discussed pretty fully in our present number.

EPITHELIOMA OF THE LIP REMOVED BY THE AID OF COCAINE.

To the Editors of THE LANCET.

SIRS,—Perhaps the following case of epithelioma of the lower lip, removed by the aid of cocaine, may interest some of your readers.

A man came to me a few days ago with a growth on his lower lip. It had been there for some time, but within the last month had rapidly increased in size. On examination I found it to be an epithelioma, and decided to remove it. He objected to the administration of chloroform; so I injected on either side of the growth a 4 per cent. solution of cocaine, and dusted the mucous membrane of the lip with hydrochlorate. After waiting ten minutes I removed the growth, and such was the good effect of the cocaine that I was enabled to take time and perform the operation with great exactness. The man expressed himself as feeling no pain, and the after progress was excellent.

I am, Sirs, yours truly,

Leighton Buzzard, Dec. 13th, 1886. JOHNSTONE HARRIS.

Dr. Glazier.—The Swiss authorities will not allow a foreigner to practise even amongst his own countrymen in Switzerland without passing the State examination at Bern or Geneva; and this is by no means a mere matter of form.

Caligraph.—Our correspondent should consult his ordinary medical attendant. We do not give advice.

J. R.—We regret we cannot satisfy our correspondent. The data for a reply are wanting.

E. S. had better address the author named.

INCOME-TAX ASSESSMENT.

To the Editors of THE LANCET.

SIRS,—Will you allow me to suggest to your readers who may be dissatisfied with their income-tax assessment that they should apply to the Income-tax Repayment Agency, 16, Artesian-road, W. Acting upon advice received therefrom I have lately recovered £7 8s., and obtained a lower assessment.

I am, Sirs, yours faithfully,

December 24th, 1886. S. W.

Viator.—So far as we are aware, Dr. Fattorini is the latest Italian writer on the probable causes of enteric fever in Rome. That author, in a comparatively recent essay, laments the abolition of the old cloacæ, and attributes the existence of typhoid in the Eternal City to the introduction of the English watercloset system.

R. C.—Such breaches of good taste are often to be attributed to the enthusiasm of injudicious friends.

ACTION OF DRUGS IN ALBUMINURIA.

Dr. Robert Saundby writes, in reference to our annotation on this subject last week, that the solution of bitartrate of potash employed was *half an ounce* to a pint, not an ounce and a half, as there stated.

J. C. is referred to our advertising columns.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Lecture

ON THE

ÆTIOLOGY OF CONSTITUTIONAL DISEASES OF THE EYE.

Being an Introduction to a Systematic Course of Lectures on Ophthalmic Medicine and Surgery, delivered in University College, London,

BY JOHN TWEEDY, F.R.C.S. ENG.,

PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY IN UNIVERSITY COLLEGE, AND SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

GENTLEMEN,—Very little experience in the observation of diseases of the eye is needed in order to discover that while some of these diseases are strictly local or due to external causes, there are others which are associated with morbid constitutional states and apparently dependent thereon. Contagious ophthalmia, the effects of injuries, errors of refraction, and presbyopia are common examples of local affections; and the ophthalmia of strumous children, the keratitis, iritis, and choroiditis which occur in syphilis, the retinitis met with in kidney disease, the cataract of diabetes, are equally common examples of ocular lesions associated with abnormal constitutional states. A still closer observation discloses the additional fact that not only are the grosser parts of the eye, such as the cornea, the iris, the choroid, the retina, or the lens, affected in constitutional disorders, but that particular portions of these parts are implicated in particular constitutional conditions. The form of inflammation of the cornea which is so common in strumous children is altogether different, both as regards its site and the mode of its manifestation, from that form of inflammation which is met with in the subjects of hereditary syphilis; and both these in turn differ from the special form of keratitis which occurs in sympathetic ophthalmitis, and in some cases of toxæmia, septicæmia, Bright's disease, and gonorrhœal rheumatism. Similar differences are observable in the various forms of iritis, choroiditis, and retinitis associated with different morbid diatheses.

What is the explanation of these coincidences and these differences? The answer to this question is by no means so easy or so obvious as might at first sight appear. But the inquiry suggested by the question is worth undertaking, because the conclusions at which we may arrive will not only explain the ætiology of the constitutional diseases of the eye, but will also throw light upon the nature and origin of other localised foci of constitutional diseases.

I may perhaps so far anticipate the result of the inquiry as to state that I believe the association of ocular lesions with general diseases is determined partly by anatomical connexions, partly by histological peculiarities of the textures severally involved, but chiefly by their embryological origins, relationships, and affinities.

The eye is peculiarly adapted for such an investigation as this. The optic nerve and retina are genetically direct and very early outgrowths from the brain; and physiology and pathology have both demonstrated what might have been *a-priori* anticipated, that there is an intimate correspondence between the development and functions of the brain and those of the optic nerve and retina. This correspondence is further increased by the communication which exists between the lymph spaces of the eye and those of the brain and spinal cord. These embryological and anatomical conditions not only account for the occurrence of neuro-retinitis and other ocular changes in diseases or injuries of the brain and spinal cord, but also for the concomitancy of retinitis pigmentosa, coloboma of the retina and choroid, microphthalmia, and other congenital defects of the eye, with faulty development and growth of the brain.

The eyeball and its appendages draw their blood-supply from two main sources—the internal and the external carotid [illegible] by means of the bloodvessels and the fluid which [illegible] or other morbific materies [illegible] blood current into the eye. Particles of fat, clots, débris, parasites, and emboli may block the central artery or other vessels, or be deposited in other parts; or hæmorrhages may occur in the retina or choroid in those states of altered blood, or altered relations between the blood and the vascular tunics, which occur in Bright's diseases, in leucocythæmia, in diabetes, &c.

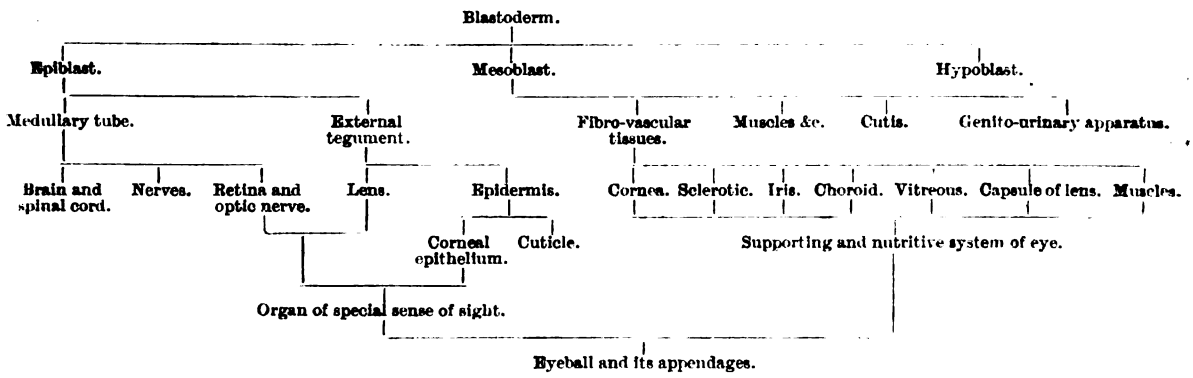
Of the twelve pairs of cranial nerves, the eyeball and its appendages receive the whole or parts of six, as well as many fibres of the sympathetic, which influence the nutrition of the eye, controlling the size of the bloodvessels, and regulating the size, equality, and mobility of the pupil. It is not surprising, therefore, that the eye is very susceptible to all those influences, healthy and morbid, which affect the nervous system generally, or the special innervating apparatus of the eye, either at the centres, the periphery, or in any part of its course. Paralysis or spasm of the muscles of motion, of accommodation, or of the iris, with the attendant phenomena of strabismus, diplopia, myosis, mydriasis, nystagmus, ophthalmoplegia, pain, photophobia, neuralgia, anæsthesia, and some forms of trophic changes, such as inflammation and ulceration, are some of the more common neuropathic ophthalmic lesions associated with cerebro-spinal disease or with general diseases which especially affect the nervous system.

There is another factor in the ætiology of constitutional diseases of the eye which has not received, as far as I know, the consideration and attention which it deserves. There is a constant relationship between the differentiation of the muscular layer of the body and that of the nervous system. Muscles imply the existence of nerves, and throughout the whole animal kingdom an intimate connexion may be observed between the power of locomotion and the sense of sight. Sessile animals do not, as a rule, possess visual organs; while free and active animals, even of lower organisation, have well-marked eyes. Some organisms which, like the medusæ, have an early sessile stage and are then eyeless, acquire ocelli when they assume a free mode of life; other organisms, like young barnacles and balani, in passing from a free to a fixed state lose their eyes with their other higher sense organs. It is, at least, noteworthy that in most cases of locomotor ataxy the sense of sight is sooner or later lost. Indeed, not infrequently blindness occurs very early, and before the appearance of actual ataxia.

So that we see the eye is not a separate and autonomous organ, living, as it were, a life apart. Nor is it a mere appendage or accessory convenient and advantageous to the rest of the organism. On the contrary, it is in the closest relationship with the rest of the body, and participates in its various moods. This inter-dependence of the several organs of the body is at once an acknowledged fact in physiology and pathology and the basis of the doctrine of evolution.

The conditions which I have already enumerated are, however, only some of the factors in the production of so-called constitutional diseases of the eye; they are not all the factors. They are, indeed, only accidentals, as it were; the essential factor being the nature and constitution of the tissue-elements themselves.

No other organ of the body contains so many different kinds of histological elements or textures of so high a quality as the eye. Not only are there the coarser constituents of bloodvessels, nerves, muscles, and fibrous tissues, but there is in the cornea a rich network of protoplasm and lymphatic channels, in the choroid a collection of peculiar pigment cells, in the crystalline lens specialised transparent fibres, and in the retina some of the most highly differentiated tissue-elements in the whole body. It is, I repeat, the number and complexity of the different kinds of tissue-elements and their kinship with many systems of similar elements distributed throughout the body which render the eye so apt to participate in constitutional diseases.



Healthy life and nutrition depend upon two conditions first, the inherent properties of the organism; and second, the environment. So long as there is a sufficient correspondence between the organism and its surroundings health is fairly maintained, but when these relations fall out of correspondence, disease, decay, or death takes place. No organism, whether unicellular or multicellular, is endowed with the power of indefinite life. In complex organisms of even the best ancestry it is scarcely likely that all the systems of tissue-elements derived from the division of the parent cell receive at birth exactly the same share of vital

Digitized by Google

energy (Ziegler). Other things being equal, the less favoured cells will succumb sooner than the more favoured to all those external agencies which are antagonistic to cell life. If these agencies exist as morbific qualities of the blood, the changes will, in accordance with what is called the law of selective assimilation, affect all the faulty elements in whatsoever parts of the body they may be located. Mr. Herbert Spencer has generalised the facts of selective assimilation somewhat as follows: "Just as the growth of an entire organism is carried on by abstracting from the environment substances like those composing the organism, so the production of each organ within the organism is carried on by abstracting from the substances contained in the organism those required by this particular organ; like units tend to segregate."

The law of organic assimilation prevails in pathological states no less than in physiological, and just as in healthy nutrition the structural elements of the body select from the nutritive particles and fluids circulating round them the pabulum proper to their composition and constitution, so in pathological states kindred elements in all parts of the body will be affected in a similar way. This is demonstrably the case in so-called blood diseases; the altered physical, chemical, or vital properties of the blood manifest themselves in local lesions of textures similar in constitution or function. The similarity of constitution is ultimately determined by the embryological origin of the tissues.

The blastoderm consists of three layers, called the epiblast, the mesoblast, and the hypoblast. From the epiblast are developed the brain, spinal cord, and nerves, the retina and optic nerve, the crystalline lens, the epithelium of the cornea, the sense-organs, the enamel of the teeth, and the cuticle. From the mesoblast the osseous skeleton, muscles, bloodvessels, lymphatics, the muscular and fibro-vascular portions of the skin and of the alimentary canal, and the genito-urinary apparatus. The hypoblast gives rise to the epithelium lining the air passages, the alimentary canal, and the principal gland ducts, and cellular elements of the associated glands. (See schema.)

A glance at the accompanying schema will show that the retina and optic nerve are not only closely related to the cerebro-spinal system, but that they and it, together with the crystalline lens and the corneal epithelium, have also a kinship with the cuticle through their common origin from the epiblast. With this help we can understand the frequent association of zonular cataract with fits and other neuroses, and a deficiency of dental enamel. So also it will be seen that the stroma of the cornea, the sclerotic, the iris, choroid, vitreous, capsule of the lens, as well as the vascular and muscular tissues of the eye, have relationship with all the other textures of the body, including the genito-urinary apparatus, which are derived from the mesoblast. The eye has no elements derived from the hypoblast. Thus we see how a histological, physiological, and also a pathological relationship is established between the epiblastic elements of the eye and epiblastic tissues in the rest of the body, and between the mesoblastic tissues of the eye and all other mesoblastic tissues. All the textures of kindred origin retain a strong family likeness throughout their existence and behave more or less similarly in similar contingencies, in spite of differentiation of structure and specialisation of function. The qualities which they have in common manifest themselves in disease as well as in health.

In applying this doctrine to actual facts, it should be remembered that all the organs and tissues of the body are not indiscriminately affected in constitutional disorders, but that in each disorder the local lesions have determinate seats, and involve only tissues or organs of a particular kind. So it is with the constitutional diseases of the eye.

In elucidation of what I have stated, it may be mentioned that Waldeyer has pointed out that sections of the cornea treated with chloride of gold and carmine present three well-defined strata of different tints. The anterior layer comprises the corneal epithelium, the anterior elastic membrane, and the immediately adjacent portions of the stroma; the posterior includes Descemet's membrane and the adjoining portions of the stroma; while the intervening layer consists of the principal mass of the proper substance. This experience, taken in conjunction with the observations of Manz, Langerhans, and others on the development of the cornea, has led Waldeyer to designate these layers respectively, cutaneous, choroidal, and scleral. As already indicated, it is certain that the anterior layers of the cornea are almost, if not entirely, epiblastic, and are therefore related very closely with the epidermis and superficial layers of the dermis, and more remotely with the cerebro-spinal system, and with the lens. The rest of the cornea is mesoblastic, the posterior layer having acquired the character and properties of a serous membrane, and being at an early stage of embryonic life apparently continuous with the choroid. It is an interesting fact that this chemical and embryological differentiation of the layers of the cornea is very closely imitated by the various forms of inflammation of the cornea. In strumous children cutaneous eruptions are common; hyperæmia, eczema, herpes, and impetigo about the lids, lips, and nose being almost invariable concomitants of the so-called strumous ophthalmia. The essential lesion in this form of ophthalmia is a vesiculo-pustule (*phlyctenula*) on the cornea, or at its margin, or on the circumcorneal zone of conjunctiva. The phlyctenula involves only the epithelial and anterior elastic layers of the cornea, or portions corresponding to those affected in the skin. So, likewise, in inflammation of the cornea dependent upon neuropathic causes, as disease of the fifth nerve, or ophthalmic herpes, the corneal change is here also primarily superficial—the epiblastic portion. In the keratitis of hereditary syphilis, on the other hand, it is the stroma of the cornea and the posterior layer which are involved—the mesoblastic portions. Now, syphilis is essentially a disease of mesoblastic textures; and those portions of the cornea, and indeed of the whole eye, which are affected in syphilis will be found to be of mesoblastic origin. The notched, pegged, and stunted teeth of inherited syphilis depend not upon faults of the epiblastic enamel, but upon those of the mesoblastic dental papillæ. The epiblastic portions of the eye may become secondarily involved; but here, as in the brain and spinal cord, the lesion begins in the mesoblastic elements—bloodvessels, &c. Inflammation of the posterior layer of the cornea (which is called by the various names—keratitis punctata, aquo-capsulitis, and serous iritis) will in the majority of cases be found to be associated with constitutional states in which inflammation of serous membranes are apt to occur—namely, rheumatism (simple or gonorrhœal), Bright's disease, septicæmia, &c. Corresponding differences and coincidences could easily be pointed out for all other parts of the eye, and for

Digitized by Google

all its constitutional diseases, but these must suffice as general illustrations.

In conclusion, however, I would suggest that the doctrine which I have propounded is available not only for the purposes of ætiology and nosology, but also for those of practical and didactic therapeutics. Many drugs and other remedial agents are already known which appear to have a special affinity for particular tissue-elements, and as therapeutical science advances their number will increase. The phenomena of "selective assimilation" would seem to indicate in localised lesions of constitutional diseases the exhibition of those remedies which are known or believed to influence the nutrition and action of kindred elements in any and every part of the body.

Harveian Lectures
ON
CANCER OF THE UTERUS.

BY J. WILLIAMS, M.D. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE I.

(*Concluded from page 9.*)

CASE 4.—The foregoing two cases illustrate the tendency of the disease to extend along the vaginal surface of the portio rather than up into the cervical canal; the next case shows this tendency in a still more marked manner.

The patient was married, forty-seven years of age, and had seven children. She had had some pain and discharge for three months, but no hæmorrhage. Menstruation was regular. The body and cervix of the uterus were enlarged but not harder than natural. There was an ulcer on the left commissure about the size of a shilling; its base and edges were not indurated. The external orifice was open, and admitted the tip of the finger as far as the first joint, and the palmæ plicitæ felt swollen. The lips were not red, but of a slightly livid hue, and there were a few points in the anterior like suppurating follicles. A small portion of the anterior lip at the os externum was removed for diagnostic purposes, and in a fortnight afterwards induration was felt in the anterior vaginal vault, without other recorded changes in the cervix. I would observe here that induration, which is so frequently mentioned as a sign of cancer of the uterus, was not present in these cases. Indeed hardness does not appear to be marked until the cellular tissue is involved in the disease. Under the microscope the flat epithelium on the surface was found to be intact, and its deeper strata sent processes into the tissues beneath and formed therein cancerous masses. It was a typical case of squamous epithelioma. The depth to which it reached could not be ascertained, inasmuch as only a small piece was removed for diagnostic purposes. The disease, however, clearly spread towards the vaginal vault, for the connective tissue in that situation became soon involved.

CASE 5.—This case is one of great interest, showing a further step in the progress of cancer of the portio. The patient was married and sixty-seven years of age. She was admitted into University College Hospital in March, 1886, with the following history: Thirteen years ago she was knocked down by a bale of goods, and almost directly afterwards she noticed that the womb came down. At first it used to go back of itself, but for the last two or three years the patient has had to return it herself. There has been occasional slight hæmorrhage for twelve months, but not much at a time. During the last three months she has become worse: there has been a continuous discharge—sometimes blood, sometimes matter. She used to suffer from a yellow discharge before she began to bleed. She could always return the womb until a few days ago, when it came down during the act of defecation, which was followed by a profuse hæmorrhage. She has lost flesh rapidly during the last six weeks. She began to menstruate in her fourteenth year; was regular every four weeks, the flow lasting five days without pain. The catamenia ceased about forty-five. She was married at twenty-eight, and has had one child and two miscarriages. There is no history of cancer or tumours in her family. There was marked rheumatoid arthritis of the inter-phalangeal joints and of the metacarpo-phalangeal of the thumbs, but not of the other digits; the wrist and elbow were also affected. The joints of the lower limbs were not affected in any marked degree. The vagina was inverted; the mucous membrane of it was pale and horny. The cervix was outside the vulva, and on the anterior part of it, and extending over the posterior half of the anterior wall of the vagina, was what appeared to be a large ulcer. This was red, and bled readily; its surface was not depressed, but the horny layer of the epithelium appeared to the naked eye to cease at its margin. The sound passed into the uterus for four inches. Temperature 99° to 100° F.; pulse 80.

An incision was made through the anterior vaginal wall about half an inch from the diseased surface, and the mass was dissected from the base of the bladder. The incision was carried round behind the cervix through the posterior wall of the vagina, and the cervix was amputated. On microscopic examination the stratified epithelium of the vagina was found thickened, and the superficial layer horny. On approaching the diseased part, the lower strata were proliferating and sending processes into the subjacent tissue. Advancing further into the disease, these processes increased in length, and cords, masses of cancer cells, and nests with horny cells in their centre were abundant. The disease terminated at the external orifice where the stratified epithelium ended; a few glands lined with columnar epithelium and a few closed follicles filled with secretion, and with their lining epithelium intact, were found in that situation. These were not involved in the cancer. In some places the stratified epithelium was very little thickened, while in others, where the disease was more advanced, it was more or less completely lost. The surface of the ulcer was generally tubercular. The disease was superficial, its greatest thickness being about three-fourths of an inch. Owing to the extrusion of the cervix and vagina through the vulva these parts were swollen and œdematous, and this naturally increased the apparent thickness of the diseased tissue.

CASE 6.—This patient, fifty-three years of age, married, was admitted into University College Hospital in May, 1884. She said that four years previously she had a slight discharge from the vagina, accompanied by pain, but had seen nothing since. Three weeks before, while in bed, she woke up with a severe dragging pain in the right inguinal region, which gradually worked round to the left hypochondriac region and then passed off. It lasted about half an hour, and left her prostrate and powerless. She had a similar attack the following night. She had had three such attacks up to the time of her admission into the hospital, one since. There was no vaginal discharge until May 7th, the day after her admission, when she observed a slight pale yellow discharge, which lasted for one day only. She had had some difficulty in passing her urine, especially when it had been retained for a long time, but there had been nothing unusual in this respect during the previous three weeks. She had suffered from nausea and eructations, dyspnœa on exertion, great depression of spirits at times which passed off after a good cry. Seventeen years ago she had pain in the supra-pubic region, but no vaginal discharge. Menstruation began in her fifteenth year, was regular every four weeks, lasting three or four days, moderate in quantity, with slight pain. It ceased at the age of forty-four. She was married at nineteen, and had four children during the first seven years of married life. She had had no miscarriages. Her labours were lingering and severe, but not instrumental. She nursed each of her children sixteen months. She had been stouter since she ceased child-bearing, but had lost flesh during the last twelve months, and had for the same period been nervous and irritable.

On admission she was well nourished, there being about one inch and a half of fat on the abdominal wall. The mucous membranes were well coloured. There was slight prolapse of the posterior wall of the vagina, and this wall was red and apparently ulcerated to within an inch of the skin of the perineum. The anterior wall seemed to be ulcerated to within half or three-fourths of an inch of the meatus urinarius; on the left side the ulcer was prolonged a little further along the wall of the urethra. At the apparently ulcerated part the vagina was greatly narrowed and its walls were rigid, so that the finger could be introduced only as far as the second joint. The lips of the cervix could not be felt. The vaginal walls were not fixed. The exami-

Digitized by Google

nation caused slight bleeding. Examination by the rectum showed that there was no appreciable thickening of the posterior septum.

In October, 1884, she had a slight discharge of blood for the first time since the menopause, nine years and a half before. It lasted one day. She had a dragging pain before it came on. She had had free hæmorrhage since with clots, and constant pain in the stomach, shooting down the legs. Defecation had become difficult and the urine escaped involuntarily. Vaginal examination at this period showed much the same condition of parts as was found at the examination made six months previously. On examination by the rectum, however, the parts appeared to be thickened, and the mass in the situation of the uterus seemed to consist of three lobes, two of which were very distinct; the mass was movable; there was some thickening on the right side. The growth was scraped with a sharp spoon and the diseased tissue was found to extend backwards into the mass just mentioned. Temperature 99·4° to 99·6°F.

Specimens of the growing part as well as of the higher and evidently older portion of the disease were submitted to microscopic examination. Beginning on the healthy surface, the squamous epithelium was found to be normal. Proceeding backwards towards the disease, the deeper layers became thicker and thrown into the appearance of folds by the papillæ growing beneath, and in the diseased part these processes became longer and entered into the tissues beneath, and masses of epithelial cells were to be discovered in the vaginal wall. The tissues adjacent to the proliferating epithelium were infiltrated with nuclei and small cells. The superficial and horny layers of the epithelium were retained almost to what appeared to be the ulcerating part; there they became thinner and thinner and ceased altogether. The scrapings from the older portions of the growth consisted largely of fibrous tissue, with what appeared to be muscular fibre cells in bundles, which formed small irregular meshes or alveoli, containing abundant nucleated small cells often presenting a granular character. In some places well-defined spaces were seen filled with nucleated cells, variously shaped, but apparently epithelial in character. Sections of these spaces presented various forms; sometimes long string-like collections of cells were seen running from them, showing apparently that these were sections of altered epithelial cords which had grown into the stroma around.

CASE 7.—This patient was forty-one years of age, married, and had had three children and one abortion. She began to menstruate at thirteen, was regular every four weeks, the flow lasting four days, in moderate quantity, and before marriage being accompanied by pain. She was married at twenty-seven. Her first labour was severe; it lasted sixty hours, and was finally terminated by forceps. She had a flooding ten days afterwards. She kept her bed for a month, and had a bad getting up. She has had leucorrhœa for three months after the periods. Four days ago she had a flooding. There is no history of tumours or cancer in her family.

On examination the vagina was found to contain much purulent discharge. The cervix was red, angry-looking, and ulcerated. There was no swelling or induration around the uterus. The sound was passed for a distance of three inches. The cervix was amputated above the insertion of the vagina. The piece removed weighed 3oz. 1dr. It was of a conical shape, and measured two inches and a half from apex to base. The base measured an inch and a half from before backwards, and two inches and a half from side to side. On the lips was a kidney-shaped ulcer, the part corresponding to the pelvis of the kidney being on the anterior lip, which was less affected than the posterior. On the posterior lip the ulcer was an inch in depth, and it split the lip in its whole length into two layers. On the anterior lip the disease burrowed in its substance from the left to the right, and had the parts been left untouched it is probable that the anterior lip would have been split in the same manner as the posterior. In some places the edges of the ulcer were everted; in others they sloped somewhat abruptly towards the healthy surface. The margin for about one-sixth of an inch felt slightly raised; the floor was irregular. The external os was near the centre of the diseased mass, close to the part corresponding to the pelvis of the kidney. It was a slit-like opening. The most extensive destruction of tissue had taken place in the posterior lip. The disease was everywhere surrounded by what seemed to be healthy tissue. On slitting up the cervix, the mucous membrane of the canal was injected, but did not appear to be diseased. The amputation seemed to have been made through normal tissue. Temperature 100° to 101°F.

On examining the specimen microscopically the squamous epithelium on the apparently healthy surface was found irregularly thickened and the papillæ enlarged. Close to the diseased part there was a very marked thickening of its deeper strata, and small papillæ penetrated into it. Between this thickened part and the edge of the ulcer the surface epithelium was extremely thin, and at one point it appeared to have been entirely lost. This narrow space was occupied, not by indifferent tissue, but by cervical tissues somewhat altered by the presence of small cells in its substance; beyond this, again, were large strings of epithelium, and between these strings cords of cervical tissue or papillæ ran. Some of these cords or papillæ ran right to the surface, having their points bare and not covered by epithelium; the points of others were covered by a thick layer of cancerous epithelium, the papillæ not having yet penetrated through it; they were bounded on each side by a similar cancerous cord. This clearly shows the mode of growth in this case. There is no indifferent tissue. The cancerous cords are formed by the ingrowth of the surface epitheljum. Papillæ often break through this proliferating epithelium, and this gives rise in sections to the apparent want of continuity of the surface epithelium with the diseased epithelium. The disease was everywhere superficial, being not more than a quarter of an inch in depth at any point; but the whole of the excavation was lined by such a layer. The new growth appeared to have ulcerated almost as soon as it was formed. The mucous membrane of the cervix was healthy, except at one part close to the disease, where the columnar epithelium had grown into several layers. On its surface were many papillæ, with an erosion presenting large branching papilliferous glands. Between the glands and the cancer there was a distinct layer of healthy tissue. The growth was independent of the glands, although in many places it assumed a form having a central lumen, which suggested a glandular origin. The disease evidently began on the surface, and then took a very unusual course for squamous epithelioma by burrowing into the substance of the cervix and then running in a circle more or less in the substance of its wall, dividing the wall into two annular layers.

I have seen but one other case which presented conditions of cervix similar to this. In that case the cervix was split completely into two circular layers. The vaginal surface of the outer layer appeared healthy to the finger. In the course of a few days the inner layer fell off completely, leaving a great conical ulcer in the place of the cervical canal. No specimen was obtained in this instance for microscopic examination, and I am unable to state the exact nature of the cancer.

CASE 8.—The patient in this case, who was thirty-five years of age, was admitted into University College Hospital in June, 1880, under the care of Dr. Graily Hewitt. She had been married sixteen years, had had nine children, but no miscarriages. The last child was born ten months previously to admission, after an easy labour. The patient had had a leucorrhœal discharge during her last pregnancy, and for the last two months she had had a bloody discharge from the vagina. She dated her illness from the first appearance of the catamenia since her confinement, eight weeks before. The flow lasted three hours, was normal, and without pain. After this she passed a clot of light colour, and subsequently larger and darker ones. The bleeding continued for four weeks, and she kept her bed and applied ice. The bleeding stopped for a fortnight, and during this time she had a white discharge; then flooding returned, but lasted only twenty-four hours; it returned again, and had continued since. She was getting weaker, but had no pain. She began to menstruate in her eighteenth or nineteenth year, and was regular until eight weeks before admission. Her periods were normal in every respect, and were almost quite free from pain. The mother died in an asylum, and the father of dropsy; brother and sisters are healthy.

The patient looked healthy; she was not anæmic, but was somewhat sallow. She had lost some flesh. On vaginal examination a tumour the size of a turkey's egg was felt projecting from the cervix; it was of the shape of a mushroom, and was everywhere hard, firm, and smooth. It grew from the right commissure and anterior lip. The sound could be introduced in the normal direction to the normal distance. The tumour, together with a portion of the anterior lip, was removed with the écraseur. It measured

Digitized by Google

two inches by one inch. When cut through it was found that its surface was decidedly softer than its central part, which cut like a fibroid. On microscopic examination the growth proved to be a fibroid polypus or a hypertrophy of the lip of the cervix, for it was covered on one side by squamous epithelium, and its surface was the seat of a superficial epithelioma of a typically squamous character. The flat epithelium was retained, and great processes were sent from it into the substance of the tumour, but they did not penetrate deeply. They formed strings and groups of cancer cells and nests, many cells among them being horny.

On looking through these cases, we find that cancer may begin at any point of the vaginal portion, from the os uteri to the vaginal vault. It may begin at more than one point—at several spots close together, as in the first case; or it may originate at the external orifice, as in the second and third cases; or it may commence on the surface of a polypus growing from the lip; it may begin, in fact, on any point of the cervix covered with stratified epithelium. The forms which it assumes in its early stages are few. Ruge and Veit state that cancer of the portio forms nodules, but the cases they describe in which the disease took this form are instances of cancer developed from connective tissue, and if they are correct as to its mode of development we must class the disease as sarcoma. Of the eight specimens I have seen, three had no special form; there was some enlargement of the lips only. In one the disease was papillary, and it was possibly the beginning of a cauliflower excrescence. True cauliflower excrescence is, I believe, rare, and is a squamous epithelioma growing from the portio. Cases are met with not infrequently presenting growths not unlike the head of a cauliflower, but they are without a stalk, and they present a firm solid structure after removal, while a cauliflower growth is a soft spongy mass which collapses after removal, and has the cervix for a peduncle. I have only met in practice with one instance of true cauliflower excrescence, and that was twelve or thirteen years ago, and the specimen was not examined microscopically. Through the kindness of Dr. Godson, however, I have had an opportunity of examining this disease in a specimen which he had removed with the écraseur, with the best results. About half to three-quarters of an inch of healthy tissue of the portio was removed together with the disease. The excrescence appeared to grow from the lip around the os uteri, was about an inch in diameter at the base when hardened in spirit, and to be altogether of the size of a small walnut. It appeared almost like a mass of tangled thread, and was entirely villous and soft. Microscopically it proved to be a squamous epithelioma growing apparently from the surface covered by transitional epithelium. One of the eight cases presented a red, tubercular surface, and one an uneven surface having a granular appearance. It should be borne in mind that a portio having a thin layer of cancer on its surface may be perfectly smooth and look fairly healthy, presenting perhaps only a little lividity. In no instance have I seen the disease start from a tear, nor is there any evidence that a laceration plays any part whatever in the etiology of the form of cancer we have been discussing.

The next point for consideration is the direction of the growth of the disease. Does it grow deeply and involve the uterine tissues, or does it extend superficially, and, if the latter, in what direction? In all the cases—six in number—in which the depth of the growth could be ascertained, the disease was found to be superficial, from a sixth to a third of an inch in thickness only, with one exception, in which it was three-quarters of an inch in thickness at its deepest part; in this instance, however, the vagina was inverted and the cervix outside the vulva constricted, and the increased thickness was probably due to the œdema and swelling caused by the displacement. Doubtless at a later stage, when the disease has destroyed the surface and invaded the cellular tissue, deeper parts are invaded, but even at a late stage it may remain superficial for a long period, as in the case in which almost the whole of the vaginal surface was involved in the disease without appreciable thickening. Later the cellular tissue in the broad ligaments, and perhaps the sacro-uterine ligaments, become involved in the disease, but in none of my cases were the latter affected.

The direction in which the growth takes is another important point in respect of treatment especially. In none of the cases was the cervical canal involved, so far as could be ascertained. In two of the eight cases this point could not be determined. In six the canal was healthy, so that the lines of the growth are not towards the cavity of the uterus, but outwards and downwards towards the vagina. It creeps towards the vaginal vault and then down along the surface of the vaginal walls. Various stages of its progress in this direction are shown by the cases given. In the first it is just beginning at several points; in the second it is growing from the os externum along the posterior lip towards the vagina; the third shows it more advanced in the same direction; in the fourth it has advanced to the vaginal vault, as shown by the thickening in that situation; in the fifth it has involved the upper part of the anterior wall of the vagina, and in the sixth it has invaded both walls for the greater part; so that the tendency of cancer of the portio—which is a squamous epithelioma—is to affect the parts superficially, and to spread on to the vagina and downwards along the walls of that tube. Whether it affects the anterior or the posterior lip most frequently I do not know, and my cases throw no light upon this point. When it grows like a cauliflower it is superficial, and enters but for a short depth into the cervix, as is shown by the cases which have recovered after removal of the growth by the écraseur, which removes, as a rule, a very superficial portion of the cervix.

There is among these cases one which has run a course differing entirely from that of all the others. I mean the seventh case. In this instance the disease appears to have commenced on the vaginal surface of the portio midway between the external orifice and the vaginal vault, and to have bored its way into the substance of the cervix, ulcerating as it grew until it had entered into the cervical wall to a depth of about one inch. It presented no tendency to spread superficially, nor to affect the tissues extensively, for the depth of the diseased tissue at any point was not more than a quarter of an inch.

In most of these cases the disease was in too early a stage for us to expect secondary deposits, and in none of them were any discovered; but in the sixth case, in which most of the vagina was affected, such deposits might have been looked for with the expectation of finding them. None, however, were discovered except some thickening in the broad ligament; the uterus was still movable, and the obturator gland and the glands in the groin were unaffected. I have seen two other cases in which the disease had spread down the vagina, but no specimens were obtained for microscopic examination, and therefore I cannot speak positively of their histological structure, although I suspect them to have been cases of squamous epithelioma of the portio. In one of these the glands in the groin were enlarged. The structure of the cancer in all the cases was squamous epithelioma. I have seen no other form commencing in the portio vaginalis, although I have seen it invaded by other forms. My cases are so few that it is but little use to discuss them further, but I must make one or two observations upon the etiology of this form of cancer. We find the earliest subject of it was thirty years of age, and the oldest sixty-seven; in two it appeared long after the menopause; while the remaining six were between thirty and forty-seven years of age: so that this form of cancer appears much more frequently during menstrual life than after the menopause.

All the patients were married except one, who was a widow. It does not seem clear that child-bearing has much to do with the disease, for one had had one child and one abortion, two had had two children and one abortion, one had had three and one abortion, one had had four, two had had seven, and one nine. Here we have five women with less than the average number of children, and three with more. Again, among all the labours none appeared to have been very bad; one or two were described as lingering and severe, but none were instrumental. In one case only was a hereditary tendency traced, a sister having died of the disease.

The previous history of the patients gives no clue to the cause of the disease. Menstruation begins early and late—at eleven and twelve, and eighteen and nineteen; and it may be regular, painless, and normal in every respect; so that, as far as these cases show, early or late development makes no difference, nor many or few children.

The symptoms are few during the early stages. Hæmorrhage appears to have been an early, perhaps the first, symptom in four, after coitus in one, independently of it in three. Discharges, white and yellow, are so common in women as to be unreliable as a symptom of cancer. There was one case in which hæmorrhage was present, but it may have been caused by the polypus present, and not by the

Digitized by Google

cancer, though against such a view is the fact that the polypus must have existed for some time before the bleeding appeared, and it is not improbable that it began soon after the commencement of the cancerous change on the surface of the polypus.

A white or yellow discharge was present in every case in a greater or less degree, with one exception: it had been present long before any evidence of the disease existed in some. It appeared before or at the same time as the bleeding in four, and it was offensive at a very early stage in two. It was absent throughout in one, even when almost the whole of the vagina was diseased. Fetid discharge is generally regarded as a sign of a late stage of cancer, and as depending upon sloughing and breaking down of the new growth. It may, however, be present during the earliest stages, and be quite independent of sloughing of the tissues. The fetor under these circumstances is perhaps due to slight hæmorrhage retained in the vagina, and undergoing decomposition and then appearing as fetid discharges.

There were few bladder symptoms of note. One had had slight scalding for many years, which she attributed to rheumatism; and one had had slight difficulty of micturition for many years, when the urine had been retained long, which may have been due to the disease, for the disease had probably existed for many years. Of the exact duration of this form little or nothing is known. The patient in one of the cases died twelve months after an operation for the removal of the disease, and the disease had existed for four months at least before the operation was undertaken; in one almost the whole of the vagina was cancerous when first seen two years and a half ago, and she was still living and in much the same condition last summer. The disease had existed in this instance probably for many years.

ABSTRACT OF THE

Lettsomian Lectures

ON SOME OF THE

MENTAL AFFECTIONS OF CHILDHOOD AND YOUTH.

BY J. LANGDON DOWN, M.D. LOND., F.R.C.S.

LECTURE I.

Paucity of Early Literature.—There is not much to be found on this subject in the early records of medicine. The earliest attempts at the education of idiots were made in France by M. Séguin at the Bicêtre. A school was established in 1842 at Abendberg, Switzerland, by Dr. Guggenbühl; but great neglect prevailed there, and the Commune had to intervene on behalf of the wretched children. M. Sægert, at Berlin, had not only been engaged in the education of deaf-mutes, but had extended his efforts on behalf of mutism from mental disease. In 1846 Germany established a special school at Leipzig; Mrs. Plumbe, Dr. Conolly, and Dr. Andrew Reed in England secured attention to the subject; whilst the claims of the feeble-minded children in the United States were brought to a practical issue by the enterprise of the late Dr. Wilbur. A school was instituted at Bath, and others in 1848 at Highgate and Colchester. Earlswood was built in 1858, and Dr. Langdon Down undertook the superintendence of this institution.

Terminology.—The term "idiot" was always avoided by parents and medical men. Idiot means "solitary," but a typical idiot who led a purely vegetative existence was scarcely ever met with except in anencephalous monsters. Imbeciles were usually regarded as less grave cases than idiots. There is, however, no definite limitation between so-called idiocy and so-called imbecility. Feeble-minded was the best term to use.

Classification of Feeble-minded.—There is a resemblance between feeble-minded children and the various ethnic types of the human family. The Negroid have characteristic malar bones, prominent eyes, puffy lips and retreating chins, woolly hair, but not black; no pigmentation of skin. The Malay variety have soft black curly hair, prominent upper jaws, and capacious mouths. The North American Indian type have shortened foreheads, prominent cheeks, deep-set eyes, and slightly apish nose. The Mongolian type is largely represented. Their characteristics are very marked. The hair is brownish, straight, and sparse; face flat and broad, without prominences; cheeks rounded and widened laterally; eyes obliquely placed, and internal canthi too far apart; palpebral fissure very narrow; forehead wrinkled transversely; lips large and thick, with transverse fissures; tongue long and thick and very rugous; nose small; skin tawny and somewhat inelastic.

Causation.—Accidental causation by malpraxis, by falls and blows, or opiates was possible, but the being able to refer a child to an ethnic type other than Caucasian precluded such a possibility. The *congenital* and *accidental* cases are well-defined from one another. But a *developmental* group must be recognised. Children may become feeble-minded, especially at the crisis of first or second dentition and puberty. The speech may be deferred or lost, and epilepsy may appear. The mind may cease altogether to develop. Those that break down at puberty usually have characteristic crania; they are dolichocephalic and prow-shaped anteriorly, the line corresponding to the medio-frontal suture being a prominent ridge. In these cases there may have been intra-uterine arrest of development of the medio-frontal synostosis; and the same cause may have also arrested the development of the cerebral centres. Over-excitement in babyhood and "over-pressure" at schools at the second dentition and puberty may be the cause of mental break-down. But, forewarned by the characteristic cranium, catastrophes may be averted. A large number of boys and girls come under Dr. Langdon Down's notice who are *not* feeble-minded, but who have the prow-shaped forehead. These are of unstable mental equilibrium. Severe frontal headache, wayward petulance, and incapacity for sustained mental work are some symptoms frequently noted. These children should not perform any serious intellectual work during the important developmental periods. "I never knew a child stammer before the commencement of the second dentition," wrote Dr. C. West, and the lecturer confirmed this statement. Dr. Down also said that he had never met with a case of stammering at that period, which did not bear evidence of its neurotic origin, which could be traced back to a period anterior to birth.

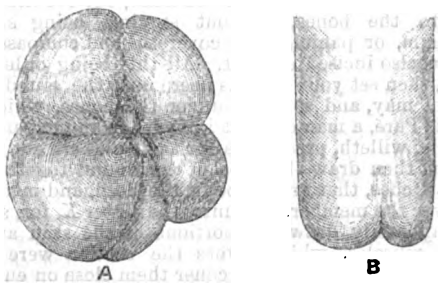
The Accidental Type.—Traumatic lesions, medications and inflammatory diseases may cause feeble-mindedness, even in children born, or ready to be born, with all the potentiality of intelligence. In these cases there is an absence of any of the physical aspects of feeble-mindedness. They may be bright in expression, active in movement, mobile in temperament, fearless of danger, persevering in mischief, and petulant. But their language is one of gesture only. Living in a world of their own, they are indifferent to ordinary changes, and yield only to the counter-fascination of music. Mothers and doctors often entertain the strongest hope of these cases, but prognoses based on the mobility and agility will prove utterly fallacious. There may be no outward sign of mental vacuity. They are cases with a vast amount of surplus nervous energy. Much may be done by training. The energy may be directed into better channels. The improvement, however, will be smaller than may be obtained from children with less promising looks. Far more improvement is to be obtained from an ill-developed than from a damaged brain. Griesinger describes the *apathetic* and the *excited* varieties of idiots. Some of his latter class doubtless correspond to Dr. Down's accidental type.

The *Congenital Type* group is a large one. The members of it are less interesting in appearance, but more amenable to treatment, than those of the preceding groups. Many years ago Dr. Down gave great attention to the physical aspects of idiocy, and contributed a paper to THE LANCET on a *cause célèbre*. Dr. Down insists on the small size of the head. Dolichocephaly rather than brachycephaly is the rule. It may be scaphocephalic, the line of the sagittal suture being raised into a "keel." Rapid shelving from the vertex posteriorly is common, corresponding to arrest of the posterior cerebral lobes. Not unfrequently the cranium is extremely small, reverting to the *Aztec* type. Even these cases are sometimes susceptible of some amount of education.

Macrocephalic Crania may be due to hydrocephalus or to an increase of the neuroglia of the cerebral mass. The

Digitized by Google

cisinitious part in some of the heavy brains is pale, and the increased weight appears to be due to increase of the white substance, especially of its connective tissue.



Asymmetry of the cranium was a notable deformation. There may be increase of the facial development in contrast with the cranial, the ears being planted relatively further back than usual. At the inner canthi the skin often forms semilunar folds—*epicanthic folds*. These are more frequent in the feeble-minded. The importance of the physical deformity of the palate was now generally admitted. High V-shaped palates were taken exception to, however, in some quarters. The front teeth may not be on the same plane as the molars. Dr. Down did not contend that all the feeble-minded had high-arched palates, but that a large proportion of those of intra-uterine origin had this physical deformity. The feeble-minded have a tendency to become stout. Sensation, both common and special, is often blunted and obtuse. Congenital cataract is commonly associated with congenital feeble-mindedness, as also are strabismus, nystagmus, myopia and hypermetropia, weakness of muscular system, automatic rhythmical movements, lateness in learning to walk, imperfect prehension with the upper extremities, postponed or absent speech, obtuse-angled jaw, large ill-controlled tongue, and defective hearing.

A SIXTEENTH CENTURY AMPUTATION.

By FREDERICK TREVES, F.R.C.S.,
SURGEON TO, AND LECTURER ON ANATOMY AT, THE LONDON HOSPITAL.

THE present taste for revivals has not extended to the re-introduction of ancient surgical procedures. It is improbable that we shall return to the "button" for arresting hæmorrhage, or to the falciform knife for excising breasts, or to the chisel and mallet for "dismembering" toes. There is little doubt, moreover, that we have seen the last of the stitching quill, the phlegme, the terebellum, and the buccas pipe. It is only by the occurrence of some such remarkable incident as is here recorded that it is possible to have any practical experience of the surgery of the past. The amputation performed in the present instance resembled in all essential points the operation as it was carried out in the Elizabethan period. For the opportunity of seeing the patient I am indebted to the kindness of Dr. Boyter Johnson, of Northumberland-avenue.

A photographer, aged thirty-five, carrying on business in Australia, having amassed a fair competency, resolved to take a long holiday. He had no children, and he and his wife determined to start for England in a sailing ship. He left Australia in May, 1886. On June 11th the ship was off Cape Horn, and was being driven before a furious gale. Before the storm subsided one of the crew had been killed and the captain and first mate injured. One sea swept the decks while the photographer was standing amidships. He was thrown violently over the sky-light and carried into the mizen rigging. When the water left the ship the man found himself suspended by the arm, and evidently much injured. After he had been assisted to the deck, it was found that there was a compound fracture of the left forearm. The limb had been terribly crushed, and a large part of the skin torn away so as to leave the tendons bare. The damage did not extend beyond the elbow. There was but slight bleeding. The ship carried no surgeon, and the treatment was undertaken by the second mate, who had no knowledge of surgery other than that dictated by common sense. The forearm was lightly splinted to a board, and the wounds covered with wet rags. The medicine chest contained some laudanum, but the victim appeared to have gone out of it, for it in no way relieved the acute pain. Four days after the accident the hand and forearm were gangrenous, and the gangrene was spreading. The patient had suffered intensely, and had had no sleep. A consultation was held between the patient, the carpenter, and the second mate, and it was decided that an amputation should be performed. None of them had ever witnessed a surgical operation—a point that was probably in the patient's favour. It was resolved that the amputation should be performed through the arm at the junction of the middle and lower thirds. The reasons were these: The gangrene had not reached the elbow, and it was considered wise to cut well above the mortified parts. (This decision was certainly in advance of th surgery of the sixteenth century.) In the second place, the brachial artery could be felt beating most easily at the place named, and it was deemed well to keep a careful eye upon the vessel when the amputation was carried out. The patient came up on the deck, which at the time was covered with snow, and took his seat upon a pile of sails. The instruments were provided by the carpenter, and consisted of a shoe knife, a saw, and a sail needle. The patient's wife furnished a sewing needle and some silk. A cord was bound tightly round the limb above the operation line. The operation was commenced by the carpenter, but his courage soon failed, and he handed the knife to the second mate, who performed the amputation with considerable skill and nerve. A circular incision was made through the skin with the shoe knife. The site of the pulsating artery had been previously noted, and the cut was cautiously deepened until the vessel was exposed. It was isolated by the sail needle, and secured in its continuity by a thread ligature. After it had been firmly tied the vessel was cut. It is probable that the ligature included the veins and the nerve. The incision was then cautiously deepened around the other parts of the limb, and a careful search made for vessels of equal magnitude that could be secured in the same way. None were found, and it is to the credit of the operator that he did not mistake the ulnar nerve for a blood-vessel. The muscles were now divided down to the bone by the same circular cut. The biceps retracted more than the triceps of course, and the mate removed an inch or so of the latter muscle to make the section even. The divided soft parts were protected and retracted by strips of linen, and the bone was then sawn through

by the carpenter. After the ligature was removed from the limb there appears to have been but little bleeding. The mate rounded off the end of the bone with the shoe knife so as to make it as smooth as possible. Finally, four vertical cuts were made in the stump so that the edges of the divided skin should meet over the bone in a point. All parts of the wound were now brought together with sutures, a sewing needle and the silk provided by the patient's wife being used for the purpose. The stump was further supported by some plaster that was found in the medicine chest. The operation was completed in the somewhat unusual time of one hour and forty-five minutes. Amputations of the arm have been performed in less time than this, but the procedure can seldom have been carried out with greater ingenuity and courage. As for the patient, it is scarcely possible to speak in too high terms of admiration of his splendid pluck and marvellous powers of endurance. The records of surgery can provide few more remarkable pictures than this: a ship on the high seas, and on the snow-covered deck a photographer, seated on a pile of sails, critically supervising the amputation of his arm by a ship's mate and a carpenter.

The patient's recovery was slow. The stump was kept covered with muslin bags filled with snow. For eight days following the operation he had little or no sleep. Many of the stitches gave way and suppuration followed. The parts were kept scrupulously clean. In time the wound healed by granulation, and the patient began to regain his strength. When I saw him early in September he was in excellent health. The stump was well and firmly healed, and was devoid of pain. A side view of the stump is shown in Fig. B, and a rough drawing of its extremity in Fig. A. (The two are not drawn to the same scale.) It will be seen that it had no tendency to assume a conical outline. The bone was well covered, and the chief peculiarity of the part was given it by the deep furrows left by the four vertical

Digitized by Google

incisions. Apart from its unusual aspect, it was an admirable stump, and reflected great credit upon the operator. The patient, a vigorous and most intelligent man, showed no other traces of his terrible holiday.

The following is the account of amputation as given by Master Clowes in his "Profitable and Necessarie Booke of Observations," published in 1596:—"You shall haue in readiness a good strong and steady fourme, and set the patient at the very end of it; then shall there bestride the fourme behind, a man that is able to holde him, or hir fast, by both the armes; which done, if the leg must be taken off beneath the knee, let there be also appointed another strong man to bestride the leg, that is to be cut off, and he must hold the member very fast aboue the place where the incision is to be made, and very steadily, without shaking, drawing up the skin and muscles; and he that doth so hold should haue a large strong hand, whereby he may the better stay the bleeding, in the place and steede of a straight band or ligature, which band indeed is also very necessarie, for by reason of its hard and close binding, it doth so benum that part, that the paine of the binding doth greatly obscure the sence and feeling of the incision; and the foresaid band is also a good direction for him that doth cut off the member; but yet in some bodies, it will not be amisse to admit bleeding according to discretion, specially in such bodies as are of hot complexions, and do abound in blood, and I have often seen, by the skillfulnes of the holder, there hath not been lost at a time fower ounces of blood; for in weake bodies it is not good to loose much blood; for blood is said to be the treasure of life. In like manner, there must be chosen another skilful man, that hath good experience in holding the leg below. And he that is the master or surgeon, which doth cut off the member, must be sure he haue a sharpe sawe, also a very good catlin, and an incision knife, and then boldly, with a steddy and quicke hand, cut the flesh round about to the bones, without staying, being sure the periosteum, or panicle that covereth and compasseth the bones be also incised and cut. All this being orderly performed, then set your sawe as neere unto the sound flesh as well you may, and so cut asunder the bones, which done, Ambrose Paré, a man of great knowledge and experience in chirurgie, willeth, presently after the bones are cut asunder, that you then draw the sides of the wound together, with fower stitches, that are deepe in the flesh, and made crosswise over the member, like unto the letter X, for, saith he, you may easily draw the portions of the skin and their divided muscles, which before the section were drawne upward, ouer the bones, and couer them close on euery side, that they may take the less aire, and the wound sooner conglutinate." To arrest the bleeding Clowes used a certain "restrictive." Later "buttons" were more generally used. It was about 1560 that Ambrose Paré urged the use of the ligature to cut or wounded bloodvessels, but more than a century elapsed before the practice came into general use.

In the "Marrow of Chirurgery," published at the commencement of the seventeenth century by "James Cooke, lover of Physick and Chirurgery," the following observation appears: "The third [mode of arresting bleeding] is stitching, which is troublesome and dangerous, on which the vessels are to be taken up and after bound, above the place amputated." This method was employed in the present instance. The curved shoe knife is probably the nearest modern representative of the falciform dismembering knife used in the sixteenth, seventeenth, and eighteenth centuries, and for which great antiquity can be claimed. The first flap operation appears to have been performed by Lowdham of Exeter, and an account of it to have been given in 1679.

In the present case the clear intelligence and shrewd sense of these inexperienced operators placed them far in advance of the primitive practitioners of surgery, and the excellent result obtained is not a flattering criticism upon the niceties of modern handicraft.

Wimpole-street, Cavendish-square, W.

ILKLEY HOSPITAL.—A sum of £1000, which, under the will of the late Mr. Thomas Emsley of Burley was left to the Ilkley Convalescent Hospital, and was paid over under a misapprehension by the executors of the deceased to the Bradford Corporation as trustees of the Semon Convalescent Home at Ilkley, has been paid over by the Bradford Corporation to the trustees of the Ilkley Bath Charity Hospital, it having been satisfactorily ascertained that the legacy was intended for the latter institution.

CLINICAL AND PATHOLOGICAL ILLUSTRATIONS OF CEREBRAL LESIONS.

BY DAVID DRUMMOND, M.D.,
PHYSICIAN AND PATHOLOGIST TO THE NEWCASTLE-ON-TYNE INFIRMARY.

(*Concluded from page 13.*)

CASE 6. *Cerebral Tumour complicated by Bright's Disease of the Kidneys; Difficult Question of Diagnosis.*—In September, 1883, a labourer, aged forty-two, was admitted into the Newcastle Infirmary complaining of severe headache, marked prostration, and loss of memory, of about six weeks' duration. His manner was exceedingly stupid and heavy, and it was with great difficulty that any history could be procured of his case. The urine was diminished in quantity, and was highly albuminous. In a few days the headache became greatly intensified, and delirium was added to his other nervous symptoms, which, from the obvious kidney mischief and total absence of all localising cerebral symptoms, were believed to be of uræmic origin. The delirium was occasionally of the most boisterous character, and it was with great difficulty he was kept in bed. By degrees the flow of urine increased, and *pari passu* the headache and delirium subsided. He left the hospital very much improved, but with the urine still albuminous. On Nov. 6th, 1884, he again presented himself for admission. Now, as before, he was complaining of pain in the head and weakness; his mental state was much obscured, so that he was unable to give a clear account of himself, and, with the addition of some emaciation, his symptoms resembled closely his condition when he first came under observation fifteen months previously. There was no dropsy. The urine contained a large quantity of albumen, but no casts, and, as he voided it in bed, it was impossible to compute the quantity passed in twenty-four hours. *There was no optic neuritis*, or other material alteration of the fundus oculi. There was an entire absence of paralysis, and vomiting did not form a feature of the case. The headache, which was general, continued, and the mental hebetude gradually deepened. He died in a fortnight from the date of his second admission.

At the necropsy, the kidneys were found to be striking examples of the so-called large pale form of Bright's disease. They weighed from 13 oz. to 14 oz. each. There was no evidence of lardaceous degeneration. The microscopic examination made subsequently of pieces hardened bore out the post-mortem-room diagnosis. The heart was not hypertrophied. The brain was soft and œdematous. At the anterior extremity of the right frontal lobe there was a gummatous tumour the size of a large fig, which was incorporated with the dura mater on the one hand and with the brain substance on the other.

In this case the symptoms of gross cerebral disease were masked by the kidney condition, for granular kidney was suspected, with a considerable show of reason. It may be said that the severity and persistency of the headache should have pointed to some cerebral affection implicating the membranes, but I have met with pure kidney cases with just as violent and obstinate a headache as in the present case. It is interesting and instructive to notice the absence of retinal changes and vomiting. I may add that I have failed in several cases of tumour of the frontal lobes to elicit a history of vomiting.

CASE 7. *Hemiplegic Hyperæsthesia.*—The patient was a remarkably well-preserved and intelligent old lady, aged seventy-five. She had led an active life, and, until quite recently, had been extensively engaged in literary work. Dyspepsia had been her only ailment until the occurrence of the attack I am about to describe. Twelve weeks before I saw her she was suddenly seized, while standing in her room, with numbness and a sense of weakness in the right arm, leg, and face, which rendered walking to the sofa a matter of great difficulty. Next day the right side was distinctly affected, especially the arm, which was numb and feeble. This condition remained for a day or two unchanged, when the feeling of numbness became aggravated, and was accompanied by an intense prickling sensation, with great tenderness. The hyperæsthesia affected the hand and foot particularly, but also the whole of the right side more or less, and continued unaltered for nearly three weeks, when it subsided to a considerable extent. With the diminished

Digitized by Google

tenderness there was a decided improvement in the motor paralysis, so that she could walk about and write a little. This improvement was only temporary, however, for, five weeks before she came under my notice, the hyperæsthesia and prickling returned, and with it a slight renewal of the motor paralysis. I found her a lively and very intelligent old lady. As she lay in bed she kept the right hand on the top of the bedclothes, and exercised a watchful supervision lest anything should come in contact with it. The speech appeared to be slightly thick and nasal, though Dr. T. W. Barron, her medical attendant, with whom I saw the case, and her friends, assured me that there was no real impairment. The forearm and the fingers were somewhat flexed, and the latter, with the dorsum of the hand, were distinctly swollen. A marked feeling of stiffness with tenderness and prickling in the arm, face, and leg was complained of. The slightest touch on the tips of the fingers, especially in the distribution of the median nerve, caused great pain, with an exaggeration of the prickling. The power of grasping was considerably impaired, but it was difficult to test this point accurately owing to the hyperæsthesia. The cutaneous sensitiveness appeared to be particularly well marked on the application of thermal stimuli. The teeth on the right side, especially of the upper jaw, were exceedingly sensitive, whilst the tongue and face were somewhat anæsthetic though tender. Taste was unimpaired, but everything taken into the mouth felt "rough" on the right side. The urine was normal. The heart was dilated, with an aortic systolic bruit. The knee-jerk was considerably diminished on the right side as compared with the left, which was by no means exaggerated. In spite of the marked hyperæsthesia of the sole of the right foot, the plantar reflex was absent. There was no apparent loss of power of the right leg.

Were it not for the distinct hemiplegic seizure involving cranial nerves, the features of this case could best be explained by the assumption of an extensive peripheral neuritis, in which hyperæsthesia is often so pronounced a symptom. But the attack was so obviously cerebral that it seems necessary to assume some vascular lesion, probably hæmorrhage, the situation and *modus operandi* of which, in the absence of post-mortem evidence, are matters of pure speculation.

CASE 8. *Thrombosis of the Basilar Artery of unusual origin.*—A man aged fifty was lately brought into the Newcastle Infirmary in an unconscious state by the police, who ascertained that he had suffered for a few days previously from attacks of giddiness, in one of which he had fallen in the street an hour before his admission. When seen by the house-physician (Dr. Waldy) his breathing was slow and laboured, the pupils were contracted, the pulse was slow (about 60) and irregular, and the left side was paralysed. Very shortly the limbs on the right side also became affected, so that there was almost complete paralysis of all four extremities and face. He died about three hours after the seizure in the street. No rise in temperature was observed.

At the necropsy the right vertebral and basilar were seen to be filled with firm clot (thrombosed). The arteries forming the circle of Willis were empty. A small quantity of fluid occupied the lateral ventricles, and the pons was slightly softer and paler than the remainder of the brain substance. The left vertebral artery was absent, so that the thrombosed vessel was simply the continuation of the right vertebral, which was dilated, except at its origin, from the subclavian, where an annular thickening of atheromatous deposit considerably diminished its calibre. This atheromatous patch was the starting-point of the thrombosis, the clot having extended from the subclavian and passed into the basilar, which vessel was entirely free from atheroma; indeed, the circulatory apparatus was normal, except for the absence of the left vertebral and the limited patch of atheroma at the commencement of the right vertebral. The impression at the time of the necropsy was that the latter was congenital.

This case is interesting as showing how a congenital peculiarity in the circulation on the one hand, and a very limited extent of disease on the other, may determine a fatal result, for in all probability, had the basilar received blood from two vertebrals, the clot arising from the patch of disease would not have altered the basilar.

CASE 9. *Purpura Hæmorrhagica; Death from Meningeal Hæmorrhage.*—J. D——, a tramp aged twenty-nine, was admitted into the infirmary on June 3rd, 1886, in an unconscious state. The following history was supplied by [illegible] stated that he was supposed to have been assaulted by one of the force. The patient was a confirmed tramp; he frequented a limekiln, in the neighbourhood of which he had lived for some time on tea and bread supplied by neighbours. A policeman was accused of striking him when removing him from the premises, and very soon after his expulsion he became unconscious. When admitted he was bleeding from spongy gums. The pupils were dilated and insensible to light. The skin was covered with petechiæ, and several well-marked brawn-like bruises were noticed on the legs and feet. From time to time a general convulsion ensued, whilst in the interval the limbs were rigid and the arms were moved spasmodically. The respiration was stertorous, and the right side of the face was puffed out with expiration. The knee-jerk was present, but not increased. There was almost constant diarrhœa. The urine was normal. The pulse was rapid and compressible; the temperature was raised, being about 100°. On the following day he appeared to recover consciousness slightly, and was able to sit up in bed, but could not be persuaded to protrude his tongue. He died twenty hours after his admission.

Necropsy.—Rigor mortis pronounced. The heart weighed 16 oz.; left ventricle hypertrophied, and right dilated; tricuspid orifice admitted five fingers. The lungs were œdematous and congested. Kidneys suggested commencing sclerosis. Brain: Bone unusually thick; the whole of the upper surface was covered by a thin layer of coagulated blood, which appeared to occupy the subarachnoid space. The clot was best marked over the left hemisphere, where it was ½ in. in thickness in some parts over the parietal lobe. A considerable quantity of fluid blood was found in each Sylvian fissure. The blood clot penetrated between the convolutions, but did not lacerate the brain surface. The substance was somewhat soft and œdematous, but was otherwise normal. There was no fracture or other evidences of injury.

CASE 10. *Acute non-Tubercular Idiopathic Cerebro-spinal Meningitis in an Adult.*—H. M——, aged thirty, a billiard-marker in a club, was admitted into the infirmary in a state of semi-unconsciousness, in which condition he had been found in his bedroom on the morning of his admission. It was stated that he had been engaged, as usual, on the previous night in the billiard-room, having retired to bed about 12 o'clock in his usual health. As one or two bottles containing patent cough mixtures were found in his room, it was supposed, when he was seen by the medical man who sent him to hospital, that he might possibly be suffering from some form of narcotic poisoning. On admission the patient was observed to be exceedingly stupid and drowsy; he could be roused with difficulty, but was quite unable to respond to questions. The pupils varied from a state of contraction to medium dilatation; to light they acted sluggishly, but responded better to efforts at accommodation. The legs and arms were occasionally moved voluntarily. There was no rigidity. The tendon-jerk phenomena were increased in the arms and legs. On the following day the patient was in a most extraordinarily fidgety state. He moved his legs about incessantly, and uttered groans as though he were in pain. When spoken to loudly, he replied in a sleepy way, stating that he had pain in his head and legs. He could now protrude his tongue, which was dry and brown. The pupils were dilated and more fixed. The temperature was raised, but never rose above 101° until the fourth day after his admission, when pulmonary œdema and congestion developed. On the third day slight internal squint was detected in the right eye, and commencing double optic neuritis was made out. A petechial eruption appeared over both knees. Talkative delirium set in. Next day a copious herpetic eruption made its appearance in the left side of the mouth, and distinct signs of congestion of the right lung were discovered. The head was now fixed, and the muscles of the back and extremities were rigid. The right side of the face was evidently paralysed, though the forehead was frequently drawn into a frown. The pupils were widely dilated. Pulse 120, compressible; muttering delirium. Next day the patient became profoundly comatose, and died on the fifth day after the onset of the attack.

Necropsy.—Brain: The veins on the surface were much distended. Some pus and greenish purulent lymph lay beneath the arachnoid. At the base a considerable quantity of the same purulent matter covered the pons and medulla, and descended the spinal canal. The same appearances were found in the Sylvian fissure and on the surface of the cerebellum. The lateral ventricles contained some turbid

Digitized by Google

fluid, and the vessels of the plexus were remarkably congested. No signs of bone disease or fracture were observed, nor was there any ear disease or tubercle.

Newcastle-on-Tyne.

SOME POINTS IN THE TREATMENT OF ACNE, ESPECIALLY OF THE FACE.

BY JOHN KENT SPENDER, M.D.LOND.,
PHYSICIAN TO THE MINERAL WATER HOSPITAL, BATH.

IF a doctor may strive to rival an artist in idealising the human face, there are few functions for which he will earn stronger gratitude than in removing the traces of disfigurement and deformity. There are, indeed, deformities which have almost classical tradition to consecrate them; and there is a native ugliness which may be to some extent glorified by the powerful lineaments of emotion and character; but most disfigurements are associated with pettiness or vulgarity, and there are few consolations for the unhappy man or woman who has a big red nose or a heavy crop of pimples on the forehead. Pimples, though veiled under the elegant Greek of the word "leichen" (λείχην), are supposed to denote the glutton or the wine-bibber, and to be beyond the rhetoric of the most subtle special pleader: for instance, if they are red, they are said to tell the tale of excess; if dotted with black spots, they proclaim uncleanliness and struma; and if only pale and insignificant, there is always the dark hint of a bad constitution in the background. Popular pathology is not always logical; and it would be difficult to convince some patients that their skin trouble is, after all, a purely local affair, depending upon inflammation or inaction of the small cutaneous glands. The purifying action of the skin is an obscure dogma to the popular understanding; and therefore people are slow to take in the fact that when Nature is baffled in her duties by too much wind, or dust, or sun, and too little soap and water, she takes her revenge by desquamations and efflorescences, and perhaps more serious things than these.

Acne (the Greek original means the "bloom of anything") is the term given to a retention of the secretion of the sebaceous glands of the skin, with secondary inflammation and deposit in them and in the hair follicles. It is characterised by red conical or hemispherical elevations or nodules; some are solid, others are filled with pus; they are found everywhere except upon the palms and soles, and affect chiefly the skin of the face, chest, and back; and they occur mostly in young persons. The disease appears to be due to the occlusion of the orifice of the hair follicles or of the ducts of the sebaceous glands opening into them. The retained secretion then becomes a source of irritation and inflammation, and suppuration follows in and around the hair sac and its appendages.[1] This, expressed in the fewest words, is the pathological anatomy of simple or uncomplicated acne.

Omitting for the sake of brevity and clearness all the intermediate forms, we may go at once to a type of disease at the other end of the scale, and speak of the so-called acne rosacea. This attacks the face and scalp alone, and is characterised by an intense reddening of the skin, due to an injection of the bloodvessels, without much swelling or tension. The serpentine vascular lines, the blood in which may be momentarily driven out by pressure, are most abundant on the sides and the bridge of the nose. This is an obstinate disease, occurring chiefly in advanced age, though not unknown in youth. However great may be the hypertrophy of the skin the disease never extends deeper than the skin, nor does it lead to ulceration.[2] Between the extreme phases of local disease thus delineated there are countless grades and shades which ought to be recognised; for they are so many tokens of constitutional power or inertness, as the case may be.

My notes of treatment profess, then, to deal only with acne punctata, acne vulgaris or indurata, and the acne rosacea, which betrays a grave alteration in the nutritive function of the skin.

The object of the practitioner should be to prevent acne punctata from passing on to acne vulgaris by getting rid of obstruction in the glands and checking the hyperæmic condition; in acne indurata, to lessen hyperæmia and promote the absorption of inflammatory products; and in acne rosacea to destroy the new growth of connective tissue.

The therapeutic points may be expressed thus:—Quiet dormant acne requires stimulation and a spur to more healthy action, while those species of acne which are marked by heat and tension call for soothing local measures. In the one case the medicinal and dietetic plan should be tonic and supporting; in the other we should advise a combination of tonic and aperient remedies and a cooling abstemious regimen.

In order to promote a healthy action of the sebaceous glands, and to prevent the formation of what are called "comedones," the following plan should be adopted, as originally described by Dr. Liveing. The steps of his method are as follows: (*a*) Steam the face every night by holding it over a basin of hot water for a few minutes. (*b*) Rub the skin for five or ten minutes with soap (I prefer terebene soap) and flannel, or with a soft nail-brush; then sponge off the soap with warm water. (*c*) When the face has been dried, a lotion should be thoroughly applied, composed as follows: half an ounce of precipitated sulphur, two drachms of glycerine, one ounce of spirits of wine, with three ounces each of rose-water and lime-water. This is allowed to dry on the skin and to remain on all night. In the morning the face is cleansed with warm oatmeal and water or weak gruel. If, for any reason, an ointment seems preferable to a lotion, a combination of precipitated sulphur and vaseline is very useful. The treatment must be modified or suspended for two or three nights if the skin becomes sensitive and somewhat tender. Dr. Liveing contends that the most common cause of failure is want of perseverance or timidity on the part of the patient or of the doctor; and that we ought not to be frightened from continuing efficacious remedies by a temporary increase in the redness and irritability of the skin.[3] If, by any chance, this plan be unsuccessful, nothing is so effective as the application of potash soap in the form of a lotion. The lotion is composed of one ounce of soft soap, one ounce of rectified spirits of wine, and seven ounces of rose (or distilled) water. This should be rubbed in vigorously with a piece of flannel for a short time, taking care not to make the skin sore. According to Dr. Liveing, the worst cases of acne will yield to the soft soap treatment if practised with necessary caution.

For eight years and more I have followed in its main outlines Dr. Liveing's plan, and with great success. But the experience which only actual work brings has led me to make modifications to suit the various susceptibilities and irritabilities of human nerves and skin. Some of these modifications I will now relate in the fewest words. In the first place, something is often required to be done during the daytime to pacify the heat and throbbing, which are part of the usual history of acne. An excellent lotion, the heritage of nearly every dermatologist, is made by combining oxide of zinc, calamine, prepared chalk, lead lotion, and lime water, to which may be added a small quantity of glycerine. Let the bottle containing this be gently waved about so as to diffuse the materials, which are only held in suspension; then pour a little into a saucer, and with a sponge (reserved for the purpose) sprinkle the face from time to time. Wipe off, when necessary, with a bit of fine muslin the powder which remains on the skin after the evaporation of the fluid, and the face may be washed occasionally with a little starch gruel. In the second place, the cases are not a few in which it is better not to use any kind of soap as part of the evening ceremonial. After the face has been steamed, we may put on a medicated jelly composed of oxide of zinc, gelatine, and glycerine. It must be liquefied by putting the vessel that holds it into hot water, and then applied with a brush. Then, thirdly, there are some sensitive skins intolerant of sulphur in any guise. When this is so, we should think of combinations of lead and chalk and zinc, blended as a quasi-ointment with the finest vaseline. There are several pharmaceutists in London and the provinces who prepare oleate of lead and oleate of bismuth; and Dr. McCall Anderson's formula of oleate of bismuth with vaseline and white wax has been aptly described as "one of the most healing of salves." Sometimes nothing agrees better than the old-fashioned but

[1] New Sydenham Society's Lexicon of Medicine and the Allied Sciences. [2] Ibid. [3] THE LANCET, Jan. 19th, 1878.

Digitized by Google

capital substance called Kirkland's "neutral cerate," which is composed essentially of lead plaster and olive oil. Whatever combination may be chosen (and only a ripe experience with a sound judgment can decide), the ointment should be smeared over all the affected parts of the face immediately after the process of steaming, and allowed to remain during the whole night. For the acne which is often a trouble to young women at the time of commencing menstruation I prescribe the following ointment with much confidence:—Ammoniated mercury, a scruple; precipitated sulphur, a drachm; oil of the sweet almond, half an ounce; and white vaseline to make two ounces. By methods such as the above, industriously carried out, an ugly, blotchy face may be commonly restored to a fair share of comeliness.

In the treatment of acne there is still room for those emollient "dusting powders" which once occupied an important place in the therapeutics of the skin. Equal quantities of oleate of zinc and pulverised starch, with a small percentage of precipitated sulphur, may be put on several times a day after moistening the surface with a warm damp sponge. Now and then a quiet acne may disappear entirely in a few weeks without any other application. But the extreme forms of the so-called acne rosacea require a whole battery of new remedial forces, as it seldom yields to mild and coaxing means. I refer with much satisfaction to a paper published in the early part of 1885 by Mr. Tom Robinson.[4] He advises no parley with an enemy which cannot be tamed or dislodged after inflammatory hyperplasia of connective tissue has once been set up. When inflamed papules are developed, a lotion should be applied occasionally, composed of bisulphuret of mercury and almond emulsion (two grains of the former to one ounce of the latter). When the congestive process goes on to suppuration the face may be fomented with hot water; and after the acute stage has subsided a combination of a scruple of yellow oxide of mercury and one ounce of lard ought to be rubbed into the face, and continued every night so long as it may seem necessary. Mr. Robinson's favourite means for tranquillising an angry skin is a lotion composed of bismuth and glycerine of starch, lessening the starch by three-fourths.

It is time to say a few words about internal remedies. It is a pity that so much attention must be given to the diet and the details of cooking, as this is the real impediment in many instances to the attainment of even a moderate success. All food which is difficult to digest must be avoided, as the waste stuff which it contains is a source of physiological irritation and worry. Simplicity will best suit that "conscience of the body" called the stomach; and regularity in the meals is of high importance. Alcohol and tobacco are usually superfluous, and sometimes poisonous; but concerning the former an exception may be made in the case of strumous young men and women, to whom a little beer (taken with meals) is often quite valuable. I must insist upon the daily constitutional walk as a necessary article of faith and practice; and I venture to add that systematic writers on diseases of the skin do not lay sufficient stress on the proper ventilation of houses and rooms (especially the bedroom) as essential to the respiratory function of the skin. This function is thwarted and blocked when the surrounding air is deficient in quantity and chemically bad in its quality; and we cannot wonder at the prevalence of acne and other similar skin diseases, when we call to mind the polluted elements which some people love to breathe.

With regard to the Pharmacopœia, the rule is almost absolute that arsenic is nearly the last drug which a practitioner should think of. Combined with perchloride of mercury, arsenic has a useful place in the management of dull inert acne in plethoric persons. Iron is often necessary, and can be conveniently given in one of two forms: either (*a*) as the ammonio-citrate, with an effervescing draught of citric acid and bicarbonate of potash; or (*b*) as the sulphate of iron, with dilute sulphuric acid and sulphate of magnesia. The mild aperient action of the latter combination is a distinct help; and further aid in this direction is afforded by the pill of aloes and myrrh. Residents in Bath can enjoy a regular and prolonged administration of the thermal waters. It is lucky that there are no reputed "specifics" in the treatment of acne; there is less scope for secret nostrums and remedies of doubtful fame; and the culture of the "general health" becomes not a vague and occult symbol but the expression of an axiomatic truth.[5]

Falstaff calls Bardolph's red nose "a perpetual triumph, an everlasting bonfire-light." Most people are only too glad to get rid of this uncanny illumination. The cure or alleviation of an old acne on the face is sometimes such a transfiguration from ugliness to comparative beauty as to bring credit to the medical adviser, gratitude from the patient, and a substantial addition to the historic glory of therapeutic art.

[4] Brit. Med. Journal, Jan. 17th, 1885.

THE TREATMENT OF INTUSSUSCEPTION.

By F. H. ELLIOTT, M.D.

THE condition known as intussusception is at all times so serious, and in so many cases fatal, that it is incumbent upon those who have had experiences similar to those recorded in THE LANCET of Oct. 23rd by Dr. Cheadle to place them on record. The following case occurred in private practice, and the facts are given from rough notes taken at the time.

On Sunday, Nov. 8th, 1885, I was sent for to see the child (eight months old) of a friend. The child, it appeared, had been quite well until the previous day, when it had been sick, for which a dose of castor oil had been given, after which a little blood had been passed by way of the bowels. When I saw it on the Sunday morning there was sickness with frequent straining, and the passage of small quantities of blood and mucus. The case appeared at first to be one of dysenteric diarrhœa, produced probably by improper feeding &c.; but on a second visit, however, the same day, I made a more careful examination, and, in addition to a sausage-like tumour, which could be distinctly felt in the left iliac region, I discovered the presence of the intussusception about three inches up the rectum. Most fortunately, I was able to avail myself of the advice and assistance of my friend Dr. G. V. Poore, who on arrival confirmed the diagnosis. By this time, in addition to the above symptoms, the child was much exhausted, and evidently in a critical condition. We decided to see what could be done for its relief, and in this we received great assistance from the father, who behaved throughout with much self-restraint and judgment. Chloroform being administered, the father held the child up by the legs, so that the force of gravity might be turned to account, and I gently inflated the bowel by means of an ordinary pair of bellows, whilst Dr. Poore kneaded the abdomen. After the lapse of a few minutes intestinal movement was audible, and on examination neither the sausage-like swelling in the iliac region nor the tumour in the rectum could be discovered, and in a short time after recovery from the chloroform it was evident that the general state of the child had considerably improved. By the next morning, however, all the signs and symptoms had returned, and the child was as bad as—indeed, worse than—before. Regarding it as a hopeless case, I did not propose to proceed further; but as a day or so passed without death resulting, I determined to repeat the operation. The inflation with the bellows this time had no effect. The tumour in the rectum did not move. I therefore fixed an indiarubber tubing on to an ordinary funnel, and, the child being inverted and the end of the tubing inserted in the bowel, had warm water poured from a considerable height, as recommended by Dr. Day in his work on "Diseases of Children." This had the effect of displacing the intussusception, but not really overcoming it, as a swelling could still be detected an inch or so above the left iliac region; I therefore fixed the indiarubber tubing on to the bellows, and passed it, well oiled, gently up the bowel until it met the obstruction. I then inflated, and in the course of a minute or so a sudden and general distension of the whole abdomen told me that the passage had been restored. The vomiting, tenesmus, &c., were almost at once relieved; milk with lime-water was retained by the stomach, and quiet, refreshing sleep ensued. For five days, although no motion was passed, everything went well; but on the evening of the fifth day the child suddenly began to shriek as if in great pain, and the whole of the symptoms and physical signs of intussusception returned. I at once took the same

[5] I am imagining an ideal patient who has no special diathetic tendency, as any complication of gout or of syphilis must be treated on its own merits and needs.

Digitized by Google

steps to reduce it as before, and with success. The most minute care in diet was observed. The child was kept absolutely still on a nurse's lap night and day. No untoward symptoms appeared, and, to my delight, on the ninth day from the last operation, and the twenty-first from the original attack, a natural motion took place. I now hoped for the best, but was doomed to disappointment once more, as in four days, without any assignable cause, the intussusception had returned again. Once more I replaced it by the means previously adopted, although I began not unnaturally to regard it as a useless effort; this time, however, it kept back, although the general condition of the child was so critical that when four days later Dr. Poore again saw it with me, we both concurred in telling the parents that we thought the chances of recovery extremely small. By the gentlest and most careful nursing in all, even the minutest, details, a gradual improvement occurred, and in two or three days another natural motion took place. A good deal of distension of the abdomen with pain—both of which were relieved by painting the walls with extract of belladonna and glycerine night and morning—remained for some few days, after which an uninterrupted recovery took place. At the date of writing this, more than a year after the events recorded, the child—a fine specimen of infantile humanity—is in the best of health, the functions are regular and natural, and, above all, the action of the bowels is unimpeachable.

I think the above details show how clearly it is our duty to persevere in all such conditions, and how much we may expect from mechanical means, carefully conducted, in reducing what may appear almost hopeless cases of intussusception.

Andover.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ON THE RELATION OF INSANITY TO EXOPHTHALMIC GOITRE.

BY M. COLMAN COLLINS, M.D., M.R.C.P. LOND.

FOR the purpose of synthesis, and to further accentuate important clinical and pyschological researches, I cull from my case-book the subjoined report, with remarks, on a patient of mine.

Miss A. B—— consulted me in 1879. Palpitation was then the most troublesome subjective symptom. The heart beats were regular, loud, and ringing. Pulse 130. The area of cardiac dulness was very slightly increased; the heart's impulse violent on exertion. There was evidently dilatation with hypertrophy. Exophthalmos tolerably well marked, and equal on both sides. The thyroid was slightly enlarged. "It never amounted to actual deformity. It simulated a bronchocele which has become stationary just at the period of its development." Its vessels and those of the neck pulsated visibly, and a hæmic murmur—the beehive hum—was heard over them. The patient was also fretful, sleepless, and dyspeptic, and suffered from amenorrhœa. Iron, digitalis, and nux vomica were prescribed, draughts of chloral and bromide were given when necessary, out-door exercise was enjoined, and the diet was attended to. Relief was so far obtained that during her sojourn at the seaside the distressing symptoms were held in abeyance, but the patient was by no means cured. On her return to her former surroundings aggravated phenomena of Graves' disease supervened. She was tried by domestic troubles, and her mind, already in a state of unstable equilibrium, gave way under the excessive strain. Physical and mental deterioration appeared to advance *pari passu* under the influence of depressing agencies. Her mind became ultimately unhinged, and she gradually lapsed into melancholia. Feelings of profound misery engendered delusions—delusions which had special reference to the necessity of joining her friends in Paradise. Consequently she "felt called upon to starve herself to death." *Per contra*, as if in still further exemplification of the morbid state of mind, she had a delusion that she was being done to death with food and physic. This amounted to a definite delusion, (*lypemenia*.) There she sat, sad, moody, and suspicious of her dearest friends. I had to feed her for a month with the stomach-pump. Obstinate constipation added to her troubles. Here I found belladonna useful; and, moreover, it appeared to mitigate occasional outbursts of maniacal excitement. (At no time did she manifest the remarkable disturbance of the affective functions, or the accompanying incessant activity, so typical of mania.) At the end of a month there was some surcease of her sorrow. A rift appeared in the cloud. The melancholic gloom was lifted, the atmosphere cleared, she no longer refused food, and she felt interested in the kind ministrations of her friends and in her comfortable surroundings. She ultimately recovered, as far as recovery was possible. I saw her lately. The palpitation, the exophthalmos, and the goitre are *in statu quo*. The melancholia has certainly left in its wake slight traces of mental weakness. She is *male sana*.

I never could elicit a clear family history or any record of insanity, epilepsy, &c. Goitre was not endemic in the district where she was born and bred. Still, it is not a work of supererogation to inquire into the obscure connexion between Graves' disease and mental alienation. Emotional disturbance, shock, and bodily and mental exertion appear to be active agents in the production of both. The cases reported by Graefe, Trousseau, Laycock, Begbie, and Friedreich may be put in evidence to support the one, and those reported by Savage and Bruck to support the other. Cretinism is, as is well known, frequently associated with bodily deformity and goitre. Dr. G. H. Savage[1] has drawn particular attention to the fact (which has previously been observed) that patients with exophthalmos sometimes become insane, and that their insanity is usually acute mania, and often proves fatal. Bruck's patient exhibited paroxysms of vertigo and mania; Geigel's was attacked by *monomania de grandeur*: mine was afflicted with melancholia, and happily so far recovered as to be able to enjoy life and earn her livelihood.

Nottingham.

EXTREME DISPLACEMENT OF THE HEART TO THE RIGHT SIDE FROM PURULENT EFFUSION INTO THE LEFT PLEURA.

BY COURTNEY NEDWILL, M.D., M.R.C.S.

THE following case seems to me to have several points of interest, and to be worthy of record:—

A little girl, aged seven years, was brought from the country to my consulting-room on May 20th for advice with regard to "shortness of breath and curvature of the spine." The history given me by the child's mother was that in November last she had had an attack of mumps, followed in February by whooping-cough, from which she was then scarcely recovered. For nearly two months, the mother stated, she had noticed that the child's breathing was very short, and that the spine was getting worse day by day. The child was of fair complexion, scrofulous-looking, and ill-nourished, had a well-marked hectic flush, was puffy over the face, and had a temperature of 100·5°. The left side was greatly distended, and the spine had an enormous lateral curve. The heart's beat was most distinctly felt at a point to the right of the right nipple.

The child was taken to a small cottage in the suburbs of the town, where I visited her the next day, accompanied by my friend Dr. Moorhouse, who administered an anæsthetic, as we found her very nervous and apprehensive of pain. A large-sized aspirating needle was thrust into the chest in the mid-axillary region between the sixth and seventh ribs, and withdrawn as soon as it was seen that pus formed the effusion, a free opening being made in the same place with a scalpel and about six inches of rubber drainage-tube inserted. Some oakum was loosely packed over the tube, which was secured to the chest by a piece of plaster. About three pints of pus escaped during the operation and on the following night. The temperature next morning was 99·2°, but fell to normal on the succeeding day, and remained so throughout the treatment, which consisted principally of milk and cod-liver oil. The child rapidly gained flesh, the discharge day by day decreased in quantity, and the tube was gradually extracted and cut off until its last piece was withdrawn on June 25th. On the 30th the fistula had healed; and on July 7th she returned to the country with the respiratory murmur clear, the heart in its normal position, and the curvature gone.

On September 1st, Dr. Moorhouse and myself had an

[1] Guy's Hospital Reports, vol. xxvi.

Digitized by Google

opportunity of examining her, and found no departure from the normal condition save the scar where the scalpel had been introduced between the ribs.

Christchurch, New Zealand.

REMARKABLE MIDWIFERY CASE: EXTRAORDINARY THICKENING AND INDURATION OF THE OS UTERI.

By Wm. Wigmore, M.R.C.S., L.K.Q.C.P.I.

I THINK the following case is worth recording:

At 3 A.M. on Dec. 8th I was called to Mrs. H——, aged thirty-nine, in labour with her third child, the last being two years old; pains had been going on since the afternoon of the day before. On examination, I found the os dilated to about the size of a five-shilling piece, head presenting; anteriorly, the os was thickened and swollen into a mass under the pubes, the rest being quite an inch thick and tough. The liquor amnii had escaped a short time before. I tried for some time to dilate, but finding I could make no impression, and the pains getting stronger and almost incessant, I applied the long forceps, hoping that with the aid of them and the fingers I might be able to dilate; but directly I used any traction, the os came quite outside the vulva, and I found it useless to attempt it. If I had used more force I should have pulled child and uterus away together. The pains were still incessant, the patient calling out for something to be done. I saw there was nothing left but to divide the os. Before doing so I wished for another opinion, and sent for Dr. Griffith of Harrow-road. He asked me to remove the forceps and let him try to dilate; but, like myself, he found it perfectly useless, and agreed with me that nothing but division would give her a chance of being delivered. I accordingly re-applied the forceps, and, pulling the os outside the vulva, proceeded to divide it posteriorly. The procedure was like cutting cartilage or tendon, and there was no bleeding; directly it was divided the uterus split right up over the head of the child, which was immediately expelled. The child was dead. I was now fearful of the consequences, daily expecting to find symptoms of metritis, cellulitis, or peritonitis; but, on the contrary, the temperature never rose above 101°. She never had any abdominal tenderness, nor even a fetid discharge, and is now quite convalescent.

Remarks.—After the birth of her first child the patient suffered from a fall of the womb, and after that of the second it became worse, and eventually quite prolapsed. She never sought any advice for it. During the whole of her present pregnancy she was sitting on it, which gave her much pain, and her favourite seat was a cane chair with a hole in it. I suppose, by the continual exposure and friction its character was quite altered. Having had a very large midwifery experience, and never meeting with a similar case, I am anxious to know what else I could have done. Craniotomy would have been of no avail, and I do not think that dismemberment would have been successful. I should also like to know how the peritoneum escaped—whether the recto-vaginal and vesico-vaginal folds were stretched by the gradual rise of the fundus and being held down below. I may here mention that after the birth of the child the uterus contracted well, the placenta came away without difficulty or hæmorrhage, and the os was drawn well into the vagina.

Inverness-terrace, Kensington-gardens, W.

THE JUBILEE AND SANITARY IMPROVEMENT.—Mr. Mark H. Judge, as a member of the Paddington Victoria Jubilee Committee, has given notice that he will propose the following resolution: "That in the opinion of this committee the dust-collecting and other trades which are carried on in connexion with the canal basin between Warwick-crescent and Praed-street, besides being a continual nuisance to the health of the parish, are during the summer months a serious danger to the inmates of St. Mary's Hospital and a source of annoyance to the Great Western Railway Terminus, which is so often visited by Her Majesty the Queen and the Ministers of the Crown; that the committee, therefore, considers that no better memorial of the Victorian Jubilee could be devised in Paddington than for the vestry to purchase the canal basin and adjacent property, in order that this long-standing nuisance may be abolished, and the site profitably utilised for residential and other purposes."

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

A CASE OF INGUINAL AND TWO OF UMBILICAL HERNIA IN WHICH RADICAL CURE WAS PERFORMED; REMARKS.

(Under the care of Mr. Sydney Jones.)

THE following cases are of interest as illustrating the radical cure of hernia by ligature of the neck and excision of the rest of the sac. In the first case the operation was performed on a boy aged three years and a half for a large inguinal hernia which could not be controlled by a truss; in the other two cases of umbilical hernia operation was urgently called for by symptoms of strangulation.

CASE 1. *Inguinal Hernia.*—A boy, aged three years and a half, was admitted on Sept. 27th, 1886. He had a right large inguinal hernia, which had existed since he was six months old. The external abdominal ring was large and patent. The hernia was easily reducible, but it had been found impossible to keep it up with a truss. The testis could be felt below the hernia, not overlapped by the latter, and appeared to be in a distinct sac.

On Oct. 15th an operation was performed under spray. The intestine having been returned, the sac was freely laid open. A comparatively narrow communication was found between the sac containing the hernia and that containing the testis. The hernial sac was divided transversely by a few light touches of the knife; the upper part was raised and ligatured at the neck, the excess of the upper part of the sac being cut away. The lower portion of the sac was turned down, and the edges accurately adapted with catgut sutures. Thicker catgut sutures were made to connect the columns of the ring. A drainage-tube was introduced, and the edges of the wound brought together by alternate silk and catgut sutures. Iodoform, iodoform gauze, and salicylic wool were used as dressings. The wound required dressing at 9.30 P.M., as the discharges were through and there was some oozing of blood.

Oct. 16th.—The temperature at 8 A.M. was 102°. There was no pain in the abdomen, but the tonsils were congested and swollen. Urine of specific gravity 1025, with no albumen.

17th.—The temperature in the night rose to 104°. The patient was restless and had little sleep, although quieter after a dose of bromide of potassium.

18th.—Tongue foul, but moist; no sickness; no distension. Ordered a pill composed of four grains of mercury and rhubarb.

19th.—Wound dressed and stitches removed; some accumulation of sero-sanguineous fluid.

20th.—Temperature 101° this morning; 101° last night; tongue cleaner.

21st.—Dark brown semi-purulent discharge from the wound. Temperature at 8 A.M. 98·4°. Patient much better.

22nd to 24th.—Much better; wound dressed with chlorinated soda lotion. Temperature normal.

25th.—Drainage-tube left out.

Nov. 9th.—No interruption to recovery since the last note. In the course of about a week the wound was healed; very firm cicatricial tissue existed in the situation of the old hernia, and the testicle was freely movable in its own tunica vaginalis. It was not thought necessary or advisable to recommend the application of any truss.

Remarks.—The above seemed a very good case to attempt a radical cure. The hernia was a very large one; no truss could keep it up, and later in life it must have assumed a very much larger size. At no time after the operation was there any reason to suspect any abdominal irritation. The high temperature shortly after the operation was, no doubt, due to congested and swollen tonsils from exposure to spray and in the operating theatre. Later on it was evident that some collection of blood and serum had accumulated in the scrotum below the tied neck of the sac.

CASE 2.—*Strangulated Umbilical Hernia complicated with Pregnancy; Ligature of Neck of Sac; Removal of rest of Sac and of redundant Skin; Cure.*—E. D——, aged forty-one, married, was admitted on Nov. 8th, 1886. The patient first noticed projection of the umbilicus after the birth of her fourth child, about eight years ago. Since then it has gradually grown larger and larger, and has lately increased a good deal in size. She says she has had what she calls a "slight touch of the cramp" in it before, but never anything like the present pain. She first began to feel bad yesterday (Nov. 7th), about 5 P.M., when she had severe pain and retching after going to the closet. She took two doses of castor oil, both of which were returned, and she was sick pretty constantly till she applied for admission. After the first attack she passed nothing per rectum, but she passed urine. She is five months pregnant, and says she always "has a very bad time" during gestation, being sick and troubled with diarrhœa nearly to the end.

On examination there was a large umbilical hernia about as big as an ordinary sugar-basin, and compared by Mr. Jones to a large mushroom, it having a somewhat constricted base. The skin over it was uneven, dimpled in places, and apparently adherent to the parts beneath. In parts it was of a deep reddish colour. It was very tense, and gave no impulse on coughing.

The patient was admitted about 2 A.M, Mr. Sydney Jones was sent for, and decided to operate at once. The patient, however, demurred, asking to be allowed to wait until the morrow. As the symptoms did not seem of a very urgent nature, her request was acquiesced in, and the operation was accordingly put off until the next afternoon. In the meantime a long narrow ice-bag was put on the tumour so as to encircle its base, but no ice was applied to the surface, as the red adherent patches of skin seemed inclined to slough. The patient after admission continued to be sick more or less, and to have severe pain at the umbilicus. The vomit was chiefly mucus, and not fæcal in odour.

At 4.15 P.M. on the day after admission, the woman agreed to be operated on. Accordingly Mr. Jones (the woman being under ether) made a longitudinal incision down the whole length of the tumour, cut through the sac by a similar incision, and exposed the hernia, which consisted of a large mass of omentum partially adherent to the sac walls, with a loop of intestine, about five inches long in the middle. The intestine was deeply congested, of a purplish colour, but shining and fairly healthy. The greater part of the omentum was ligatured and removed, and the sac walls cleared. The sac was then dissected away from the skin and removed, all but a short neck, the constriction having been relieved by an incision directly upwards from the umbilicus, which allowed a small piece of healthy intestine to come up. The intestine was replaced, and the neck of the sac secured by a stout green catgut ligature tied firmly twice round it. As this seemed to cut the neck of the sac, and a small quantity of fluid continued to regurgitate, three or four catgut sutures were used till the opening seemed to be completely closed. The margins of the umbilical aperture were brought together by three catgut sutures. The greater part of the skin which had covered the hernia was then cut away, leaving sufficient to allow the margins to be brought loosely together; and the incision was closed by alternate silk and catgut sutures, a drainage-tube being placed along about three-quarters of the length, and opening below. The operation was performed under spray, with antiseptic precautions, and the wound was dressed antiseptically with iodoform and salicylic wool. The patient being very stout and the abdominal walls loaded with fat made the operation more difficult.

Nov. 10th.—The patient was sick once last night after the operation. Temperature at 8 P.M. to-day is 100·4°. She slept fairly well last night, having in all seven hours' sleep. A catheter was used.

11th.—The patient has been able to pass urine since the night of operation. Last night (Nov. 10th) she was sick three times—first time at 8 P.M., then at 10 P.M., and again this morning at 4. She had not been taking any food, and the vomit is small in quantity and looks like contents of stomach. There has also been a little diarrhœa. Tongue dry, but not so dry as yesterday. Pulse 108, full, soft. She slept fairly well last night (four or five hours), and feels this morning quite comfortable. Temperature 99·4°. She takes two teaspoonfuls of milk every half-hour, also four teaspoonfuls of meat juice in the twenty-four hours, and some barley-water.

12th.—Wound dressed under spray; its edges seem to be united, and it looks very healthy. Drainage-tube left in; not much discharge.

13th.—The patient was sick two or three times during the past twenty-four hours. Some diarrhœa; bowels open four or five times. Enema of starch and opium given at 2 P.M. yesterday. Temperature this morning 99°; pulse 98.

14th.—Bowels open twice yesterday; not much diarrhœa. Temperature 99·6°; pulse 112. The patient feels weak, but otherwise well. Tongue pale and moist; no pain or tenderness in the abdomen.

15th.—Morphia injections have been used until to-day; they are now stopped. She sleeps better; she has slept about from three to five hours each night since the operation. Her sleep is not continuous.

16th.—The wound was dressed to-day under spray. It is healed except where the tubing was inserted. Tubing left out and stitches removed. Temperature 99°. Tongue brownish fur but moist. The patient was sick at 2 A.M. yesterday, and again to-day at 8 P.M.

17th.—Bowels open five times yesterday; very loose motions. Pulse 112. Three or four hours' sleep last night.

18th.—Patient had a better night; slept five hours. Pulse 80, fairly strong. Tongue moist, covered with brownish fur. Temperature 98·4°. She has had a little bread-and-butter and tea this morning. She has complained a good deal for the last day or two of being hungry.

20th.—The wound was dressed yesterday afternoon under the spray, and is now healed. She has not been sick since the 18th. Sleeps better, four or five hours a night. Pulse 92; tongue furred, but moist. Temperature 98·8°. Custard was given yesterday, besides bread-and-butter.

21st.—Bowels opened nine times yesterday and last night. An enema of starch and opium was given last night.

22nd.—Bowels moved six times yesterday. Motions loose, but not much in quantity. Pulse 108, full and strong. Temperature 98°. Fish and custard diet ordered.

23rd.—Bread-and-milk diet to-day, and chicken. Bowels not relaxed last night. She slept much better last night. Temperature 98·4°.

24th.—Wound dressed with iodoform and salicylic wool. No spray. Wound healed in greater part. Very little discharge. Temperature 97·8°. Bowels opened twice in twenty-four hours; not loose.

26th.—Patient much improved; no sickness or diarrhœa. The dressings were left off except a little iodoform gauze. The edges of the wound are strapped together, and have been from the first. An abdominal belt, with an oval stiff plate corresponding to the wound, has been applied. The patient feels much more comfortable, and got up at mid-day.

27th.—Full diet ordered.

29th.—Patient is better; no sickness or diarrhœa. She feels quite well when up, and is to go out to-morrow.

CASE 3.—*Umbilical Hernia: Operation; Removal of Omentum; Ligature of Neck and removal of rest of Sac; Removal of redundant Skin; Cure.*—A fat woman, aged thirty-five, was admitted on Dec. 4th, 1886. The first appearance of swelling was about five years ago, during a confinement. She has had two children. About ten months ago she had an attack of severe symptoms in connexion with her hernia; but the latter was then reduced, and she has worn a belt ever since. On Dec. 1st, at 7 A.M., she had sudden vomiting, preceded by pain in, and enlargement of, her hernia. The vomiting continued, becoming much worse on the 3rd, and the pain was so great about the umbilical and epigastric regions as to make her, as she said, "raving mad."

On admission there was seen a large lobulated tumour, fairly circular, about 4 in. in diameter; it was sessile, except below. The skin was soft, but not discoloured. The tumour appeared omental, but it was difficult with certainty to say. There was some impulse; the skin was puckered, and the sac evidently much pouched. An ice-bag was applied for some hours, but without relief to the pain, which seemed very great. At 2.30 P.M. she was operated on by Mr. Sydney Jones. No attempt was made to divide any structure external to the neck of the sac, but a median incision was made to lay open the whole interior of the sac. There was much fatty omentum, which had long been adherent to the interior of the sac, with, in addition, a very large piece of omentum, much congested, with large engorged vessels. No intestine

Digitized by Google

was found in the sac. The old adherent fatty omentum was removed. The recently protruded omentum was ligatured with catgut, and the stump passed into the abdomen. The sac was dissected out, the neck was ligatured, and the excess removed. The pillars of the ring were brought together by three catgut sutures. The excess of skin was removed, and the margins of the skin wound, after the insertion of a drainage-tube, were brought together by silk and catgut sutures. Iodoform and salicylic wool were used as dressings. Her pain ceased directly after the operation. She had some sickness and restlessness, which were remedied by subcutaneous injections of morphia.

Dec. 7th.—Fairly well since the operation. No tenderness. Temperature 101° to 102°; wound disposed to suppurate.

11th.—The wound was dressed last night; much discharge; suppuration around the sutures; these were removed and strapping applied. Boracic dressings were used. The suppuration gradually diminished, and she left the hospital well, with an abdominal bandage, before Christmas.

Remarks.—The two above-described cases of umbilical hernia indicate pretty well the plan of treatment which should be adopted in cases where umbilical hernia calls for operative treatment. In these cases in former times operation had a serious result, and on this account surgeons undertook such operations with fear and trembling. No doubt the proper plan to pursue, when operation is called for, is to cut at once, under antiseptic precautions, into the sac; to divide the constricting neck of the sac and return any strangulated intestine; to remove the omentum, ligaturing it at its neck, and return the stump into the abdomen; then to dissect away the sac, ligaturing this at its neck. In this way any blood or inflammatory products are prevented getting into the peritoneal cavity. To complete the operation the margins of the umbilical aperture are brought together by catgut sutures; the redundant skin is removed, and the edges of the skin wound are brought together by alternate silk and catgut sutures, drainage under the skin wound being used, and antiseptic dressings afterwards applied. In the above two cases, after returning the hernial contents a ligature of the neck of the sac was first employed, next sutures connecting together the margins of the umbilical aperture, and lastly sutures connecting the skin wound after the excess of skin had been removed. Both cases did well, although they were, as is usually the case, bad subjects for operation. In the first case, after operation there was more or less sickness; but she was pregnant, and it was her usual condition in previous pregnancies to suffer from sickness and diarrhœa from the beginning to the end of such period. This case healed by first intention, as is usual in cases after ovariotomy. In the second case there was some suppuration during the healing of the wound. In this latter case there was no strangulated intestine in the sac, but there had been a large addition of omentum in its interior. This omentum showed signs of intense congestion, and might have exerted pressure in some way upon intestine. The patient's pain was excessive, as was her vomiting, so as to call for operative interference; and this interference has resulted in her having got rid of her hernia.

SWANSEA HOSPITAL.

HIGH ANEURYSM OF FEMORAL ARTERY; LIGATURE OF EXTERNAL ILIAC ARTERY; CURE.

(Under the care of Mr. H. A. LATIMER.)

E. A. H——, aged thirty-four, a fitter by occupation, was admitted on Sept. 7th, 1886. He had that day made the journey to Swansea from Bridgend by rail. About two years before admission he severely strained himself in his work, and on the same night he felt a pain in the groin, which was followed by swelling of the scrotum. He states that this swelling was due to a rupture, and that he was able to return the bowel into the abdomen, but he never had any advice on the subject, and a truss which he applied and wore five months before his admission was of a very primitive nature. The wearing of this truss caused great pain, extending from the hip-bone to the seat of the aneurysm. He bore with this up to two months before admission, when he consulted a medical man, who immediately ordered him to bed. He states that, "when lifting anything heavy, when I had the truss on and my bowels came down, the beating and pain was unbearable." He first noticed this pulsation one month after taking to the use of the instrument. Has always been a great walker. Has never had syphilis. Had acute rheumatism at the age of sixteen, and gonorrhœa at seventeen years of age. Is married. Is generally abstemious, and has never drank spirits. The family history is scanty. A sister died of phthisis pulmonalis.

On admission there was a tense, pulsating tumour at the upper and inner part of the right thigh, of irregular outline and well elevated; it extended from Scarpa's triangle right up to Poupart's ligament, and thence to the side of the pubis. The impulse proceeding from it was eccentric. The right leg was swollen throughout. Comparative measurements gave the following: Right thigh over tumour 23½ in., left 18½ in.; right thigh at Hunter's canal 19½ in., left 15½ in.; right knee 15½ in., left 13 in.; right calf 15½ in., left 12½ in.; right instep 11 in., left 9½ in. The patient had suffered much pain of a continuous aching character, and extending along the right thigh from the anterior superior spine of the ilium downwards to the outer side of the knee-joint. No pain at any time in the aneurysm. No albumen in the urine. The heart was free from any abnormal bruit. The temperature by the mouth on the evening of Sept. 8th was 101°.

The external iliac artery was tied on Sept. 9th under carbolic spray. The incision practised by Sir Astley Cooper was made. The artery was ligatured with a double layer of No. 4 carbolised chromicised catgut, and the dressings employed were protective and gauze. His leg was then bandaged with flannel over cotton-wool, and he was placed on a water-bed with the limb elevated and surrounded with hot-water bottles.

The after-progress of the case was one of uninterrupted recovery. No pulsation at any time again showed itself in the aneurysm, and after a day or two all pain subsided. He was allowed to rise on Oct. 26th. The swelling in the limb began to subside very quickly after the operation had been performed, but it was found later on, on removing the flannel bandage, that two ulcers had formed on the outer side of the leg, no doubt from trophic nerve disturbance. They were situated over the peronei muscles at about the middle of the limb, the upper one being half an inch in length, and the lower one an inch and a half in length. Deep-seated suppuration and limited gangrene of the muscles at that spot took place, and on Nov. 4th a rigor, with rise of temperature to 104·2°, took place; all this trouble was immediately relieved by preventing the bagging of matter by means of carefully placed drainage-tubes. He was discharged on Dec. 6th, when the aneurysm sac was still to be felt as a hard lump, absolutely devoid of impulse, and painless on handling. The larger of the ulcers was still very slightly open; the smaller ulcer had healed perfectly.

STAMFORD INFIRMARY.

CALCULUS IN A BOY; REMOVAL BY LATERAL LITHOTOMY; CURE.

(Under the care of Dr. NEWMAN.)

H. I——, aged thirteen, was admitted on Aug. 25th, 1885 A stunted, white, unhealthy lad. Is said to have had symptoms of urinary irritation for a period of seven years. Constant incontinence, always in pain after passing urine. He has a long prepuce, with minute orifice.

On Sept. 1st circumcision was performed, and the patient sounded. A calculus of some size was readily struck. On Sept. 9th lateral lithotomy was performed, using Chiene's staff and a plain scalpel. The finger following the knife at once came on the stone, lying across the wound. This position was rectified, and the vesical wound enlarged with a probe-pointed hernia knife. The stone was seized with a pair of small straight forceps (in its long diameter), and very slowly extracted. Little hæmorrhage followed. The calculus was flattened, oval, and weighed 580 grains. Had not one bad symptom. On the fourth day urine was passed per urethram. On the tenth day it was noted that all the urine passed per urethram, and on the fourteenth day the wound of the operation was perfectly healed. On Oct. 5th the lad went home quite well.

Remarks.—The case noted above seems to be worth putting on record. The points of special interest are the long duration of very severe symptoms, the size of the stone, and the rapid repair of the surgical wound.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Multiple Cavernous Angiomata.—Melanotic Tumour of Breast.—(?) Recovery from Tubercular Meningitis.—Raynaud's Disease and Peripheral Neuritis.—Rupture of Syphilitic Cardiac Aneurysm.

THE annual general meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., president, in the chair. The list of officers and Council for the ensuing year is appended to this report. The vote of thanks to the retiring President was proposed by Dr. T. Barlow, seconded by Mr. James Black, and carried by acclamation. The vote of thanks to Mr. Butlin, proposed by Dr. Goodhart and seconded by Mr. R. W. Parker, was also warmly received.

Mr. F. S. EVE showed a specimen of Multiple Cavernous Angiomata of Leg. They were distributed along the internal and external saphenous veins, chiefly subcutaneous, but some were lying deeply in the popliteal space. On three of the digits were calcified enchondroma; exostoses were found on each end of the tibia. A sarcomatous tumour sprang from the back of the tibia and included an angioma. Spaces bound with connective tissue were seen under the microscope, and these spaces could be injected from the vein. The sarcoma was a round-celled one. The tibia was bowed backwards, and showed a defect in organisation of osseous tissue. Phleboliths were contained within the angiomata. In Billroth's last edition some mention was made of multiple angiomata. Dependence of tumours on defective development was illustrated by the present case.—Mr. C. J. SYMONDS said Mr. Howse had recorded a similar case in the Guy's Hospital reports.

Mr. H. T. BUTLIN showed a Melanotic Tumour of the Breast taken from a woman aged sixty-four, who was first operated on in 1880. The tumour was of seven months' duration. There were no adhesions, no enlargement of glands, no retraction of nipple, and no peculiar colour of skin. The breast was removed. Recurrence took place, and a fresh operation was performed in 1882; from beneath the scar the recurring tumour was removed. In 1884 a third tumour from the same situation was excised; and recently another tumour was cut away. There was no sign of disease of any internal organ. The section was brittle and rendered microscopic preparations difficult. There were many tiny, very bright nævoid spots in the skin that were considered to suggest carcinoma. He believed it was a sarcoma with a distinct alveolar structure. There was a similar case in a woman aged sixty-eight in Billroth's article on the Breast in the *Deutsch. Chirurg.* Gross allowed of melanotic carcinoma, but not sarcoma. The melanotic granules appeared to be in the intercellular substance in the fibroid bands.—Mr. A. A. BOWLBY said that there were many small pigmented spots. The growth was exceedingly friable. He did not think there was true melanosis. He concluded that it was a sarcoma from the distribution of the blood-vessels.—Mr. D'ARCY POWER said that the structure was peculiar; a base of connective tissue existed on which filaments sprouted, as happened in the growth of some fungi.—Mr. BUTLIN wished to have the specimen submitted to the Morbid Growths Committee.

Dr. CARRINGTON read a case of old Phthisis and recovery from Tubercular Meningitis. He admitted that the case was open to criticism, but, inasmuch as it must have occurred to most to have at least suspected meningitis in cases that eventually recovered, he thought that any post-mortem evidence bearing on the point was worthy of discussion by the Society. The patient was a boy aged sixteen, a clerk. Three sisters had died in infancy, but the family history was otherwise good. On July 4th he was knocked down by a tricycle, which struck him on the right knee, but he only kept his bed for a week. Still, however, the knee continued to swell, and in the course of a year movement became much impaired. Fifteen months after the accident the left knee became affected, and eventually this joint also became to a degree fixed. The boy improved under treatment, but on Jan. 26th, 1886, he was readmitted with psoas abscess on the right side. He again improved by treatment, and was discharged on April 24th, but was readmitted on Oct. 2nd with another abscess on the left side; he gradually sank and died. After death the pi-arachnoid was found to be generally thickened, and the sulci were matted together. The membranes were granular, and exhibited small yellow tubercles, as was confirmed on microscopical examination. There was meningitis, probably of more recent origin, of the lower third of the cord; the brain and cord were healthy, except that the latter was softened. At the apex of each lung there were old phthisical lesions. The fourth and fifth lumbar vertebræ were carious, and the right knee-joint completely disorganised. With the exception of lardaceous disease of the spleen and small intestine, the other viscera were healthy. As regards the tubercular nature of the old meningitis, Dr. Carrington was inclined to lay much stress upon the concomitance of old tubercular phthisis, old cerebral meningitis, caries of the spine, and chronic joint disease, as evidence of the tubercular nature of the meningitis, which he believed had been recovered from, but he thought the naked-eye and microscopical appearances were equally distinctive. The spinal meningitis was probably of more recent origin, and due directly to the cause. If the origin of the disease was claimed as due to the accident, it was curious that the second knee was not affected until fifteen months afterwards, and there certainly could not have been any cerebral meningitis at the time, for the man only kept his bed for a week, and then went to his work as a clerk. On the whole, he suggested that there was evidence of bygone tubercular meningitis, probably approaching in date the old phthisis.—Mr. S. G. SHATTOCK suggested that the meningeal appearances were somewhat like those of periarteritis, as shown by Dr. C. Turner.—Dr. J. S. BRISTOWE raised the question whether the nodules of tubercles were necessarily ancient.—Dr. CARRINGTON said that the tubercles were yellow and caseous, and adherent by fibrous tags. He felt sure that they would be found to have no connexion with the arteries.—In reply to a question, Mr. TARGETT said the intellect was unclouded.

Dr. COUPLAND showed for Dr. Wiglesworth specimens of Peripheral Neuritis in Raynaud's Disease, the subject being a female inmate of Rainhill Asylum, aged twenty-six, who suffered from chronic Bright's disease and dementia, with epilepsy. Before her admission in December, 1884, she had sustained amputation of several of the fingers and toes for gangrene, and whilst under observation she suffered from ulceration of these extremities, and in January, 1886, the terminal phalanx of the fourth left finger became gangrenous and required amputation. The patient died suddenly in May, 1886, after an epileptic fit. The kidneys were markedly granular. The spinal cord and several of the nerve trunks of the limbs were examined microscopically. In the cord the chief change was in the posterior vesicular column of Clarke, where the cells were rounded, their processes being ill-defined; and the neuroglia of the white substance appeared slightly thickened. In the nerves there was an overgrowth of the fibrous elements, with atrophy and degeneration of the nerve fibres—e.g., the left posterior tibial nerve presented thickening of the epineurium, perineurium, and endoneurium, with atrophy of the nerve tubules. Similar changes occured in other nerves, and were better marked in those of the left limbs than in those of the right. The changes were more marked at the peripheral than in the larger nerve trunks. Dr. Wiglesworth left the question open whether the change was primarily a chronic interstitial inflammation invading the nerve bundles and causing their atrophy, or whether it was a primary degeneration of nerve tubules with secondary hyperplasia of the fibrous framework; but he considered that the case removed Raynaud's disease from the category of neuroses, and showed that structural lesions of the peripheral nerves underlay it.—Mr. A. A. BOWLBY had examined the nerves, and found indentical changes. He thought it was very likely to be a disease dependent on lesions in the peripheral nerves; the stiffening of the joints pointed in the same direction. M. Pitres had recorded a similar case.—Dr. THOMAS BARLOW said similar cases had been recorded by Pitres and Mountstein of Strasburg, but the changes were not so extensive as in Dr. Wiglesworth's case. Though important contributions, they did not solve the difficulties. Raynaud's disease was divisible into several classes. There were chronic cases like Dr. Wiglesworth's, and the genuine or paroxysmal cases, which were as fit-like as a rigor in an attack of ague. The occurrence of paroxysmal hæmoglobinuria and attacks of amblyopia and jaundice seemed to show that there must be a wider pathology than a peripheral neuritis. It seemed as

Digitized by Google

though there were vascular storms, perhaps dominated by vaso-motor centres of the cord.—Dr. HARRINGTON SAINSBURY asked whether there was any Bright's disease, and what the condition of the peripheral vessels was.—Dr. J. A. ORMEROD said that in these cases there were not the symptoms of peripheral neuritis. He had recorded in the St. Bartholomew's Hospital Reports some paroxysmal disorders that seemed to be dependent on mild neuritis: loss of power, with pains, and the backs of the hands swelled. It would be interesting to associate such conditions with other paroxysmal ones like Raynaud's disease.

Mr. WITHERS GREEN showed a specimen of Ruptured Aneurysm from a barrister, aged thirty, who had drunk hard, but there was a clear history and evidence of syphilis. The patient died suddenly. The pericardium was distended with black clot, and a soft fawn-coloured bulging of auricular shape, the sac of an aneurysm of the wall of the right ventricle. A yellowish-white gummatous-looking swelling was seen around the aneurysm. The clear dependence of the ruptured aneurysm on syphilis was the great interest of the case.

The following card specimens were shown:—Mr. Butlin for Dr. Davies: Maternal Impressions; Purpura of Hands and Face in a New-born Child, who died in three hours. The mother was said to have been strongly impressed by the sight of a case of hæmorrhagic purpura one month before her delivery. Mr. Targett: Congenital Deformity of Leg and Foot. Mr. Eve: (1) Multiple Painful Lipomata of the Arms: (2) Diffuse Unilateral Papilloma of the Tongue. Mr. Charters Symonds: Hydatid of the Breast. Mr. J. R. Lunn: Tumour of the Clavicle displacing the Larynx. Dr. Drewitt: Aneurysm of Mitral Valve. Dr. Sainsbury: Hæmatoma of Dura Mater. Dr. G. N. Pitt: Carcinoma of the Spine and Liver, with Deposit in Douglas's Pouch. (Recent specimen.)

The following is a list of office-bearers for the ensuing year:—President: Sir James Paget, Bart., D.C.L., LL.D., F.R.S. Vice-Presidents: Drs. Henry Charlton Bastian, Syer Bristowe, T. H. Green, Douglas Powell, Sir Joseph Lister, Bart., D.C.L., LL.D., F.R.S., Messrs. Morrant Baker, Sydney Jones, and T. P. Pick. Treasurer: Mr. John Wood. Honorary Secretaries: Dr. Sidney Coupland, Mr. Rickman Godlee. Council: Drs. Robert Edmund Carrington, Henry Radcliffe Crocker, David White Finlay, James Kingston Fowler, James Frederic Goodhart, Walter Baugh Hadden, Arthur Edwin Temple Longhurst, Norman Moore, Joseph Arderne Ormerod, Felix Semon, Messrs. A. A. Bowlby, H. Butlin, W. Cheyne, Frederic S. Eve, H. Golding-Bird, J. H. Morgan, S. G. Shattock, J. B. Sutton, Charters J. Symonds, Frederick Treves.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Typho-malarial Fever.

AT a meeting held on Dec. 8th, Dr. W. Dickson, R.N., President, in the chair,

Dr. J. E. SQUIRE read a paper on the above subject, of which the following is an abstract. When observing the fever which occurred amongst the troops round Suakim during the campaign last year, Dr. Squire realised that there were two diseases present, both possessing similar symptoms, which led to their being diagnosed as enteric fever. Post-mortem examination showed the diagnosis to be correct for some of the cases, but in others, similar as to symptoms, the absence of the enteric lesions which were expected to be present proved that these latter were not enteric fever. The definition of the term "typho-malarial fever" requires to be agreed upon before proceeding, for opinions differ as to its signification. The College of Physicians, following the opinion expressed by the International Medical Congress at Philadelphia in 1876, places the name as a subdivision of enteric fever and describes it as a "combination of malarial and enteric fevers"—in other words, a compound fever resulting from the simultaneous action of two distinct poisons. A somewhat similar view was upheld before this Society in 1881 by Dr. E. G. Russell, who speaks of typho-malarial fever as an example of the parallelogram of forces, it being, as he considers, the resultant of the two poisons of malarial and enteric fevers. Dr. Woodward, who gave us the name, considers it a hybrid between these two diseases. Against these views the writer protests and gives preference to the opinion that typho-malarial fever is not a result of the enteric fever poison, but a form of malarial fever, and he gives as a definition that "typho-malarial fever is an expression of the malarial poison (or a malarial fever) in which intestinal and adynamic symptoms are prominent, causing the illness to simulate enteric fever." The College of Physicians, in saying that typho-malarial fever is a combination of malarial and enteric fevers, probably intend to signify that the one is modified by the other; not that a distinct disease—a hybrid, in fact—is produced, as would be suggested by Dr. Russell's simile of the parallelogram of forces. The belief in hybrid diseases should be passed for ever. A specific poison produces a specific disease with certain pathological results. The symptoms may be modified by a variety of causes within or external to the patient; or two poisons may enter the system at the same time, and one may then delay or modify the manifestation of the other, but no new disease is thereby produced. If the term "typho-malarial fever" expresses nothing to men's minds beyond a modification of enteric fever, or a hybrid disease, it is not worthy a place in our nomenclature. But if a poison absolutely distinct from that which produces enteric fever, and with a different pathological manifestation, may, under certain conditions, cause symptoms closely resembling enteric fever, and an illness often mistaken for this disease, then we have a morbid state of much interest and of great importance, and one which has a claim to special recognition. This would appear to be the case with regard to the subject of this paper. The term "typho-malarial fever," having at length been included in our nomenclature, should remain; but it should be transferred from its present position under "enteric fever," and be placed as a subdivision of malarial fever. The pathological signs, rather than the symptoms, serve to show the differences between typho-malarial and enteric fevers; and where the necropsies disclose the Peyerian ulceration of enteric fever, the latter disease is indicated. Dr. Squire's experience at Suakim showed that besides cases of true enteric fever, verified post-mortem, there were other cases diagnosed as such in which the necropsy showed an absence of ulceration in Peyer's glands, even after three weeks' illness, and only a general congestion of the intestinal mucous membrane. Other instances were referred to, especially an outbreak of fever in two regiments in the Bengal Presidency, recorded in the Army Medical Report for 1879, in which similar experience showed the existence of enteric fever side by side with cases closely resembling this disease, but in which the intestines were unaffected. The course of typho-malarial fever is thus described: Tonsillitis may occur as a premonitory sign. The onset is sometimes more sudden than that of enteric fever, and bilious vomiting is often an early and persistent symptom. Diarrhœa is frequently, but not invariably, present, the stools being greenish or resembling those seen in enteric fever. Congestion may extend along the whole length of the alimentary canal, causing nasal catarrh, or symptoms resembling dysentery. Later on the tongue becomes dry and brown, and sordes appear. Mental apathy gives place to low muttering delirium, with subsultus and other signs of the typhoid condition; and death may result from exhaustion, or a prolonged convalescence keeps the patient in hospital for weeks or months before the absence of diarrhœa and evening fever allows of dismissal from hospital. The temperature, though often resembling that of enteric fever, reaches a high point earlier in the illness, and the daily range is greater. The absence of rose spots is invariable. The symptoms being thus so similar to those of enteric fever, we must turn to the pathology of the disease to see the great distinction between the two, their differentiation being of importance from the differences in etiology. Speaking generally, the difference is found in this: that whereas cell-proliferation and subsequent ulceration in Peyer's patches and the solitary glands of the ileum is the pathological sign of enteric fever, such ulceration is rarely, if ever, found after death from typho-malarial fever. As in other malarial fevers, ulceration may be found in the intestines in typho-malaria, but it does not select, and is not confined to, Peyer's patches and the solitary follicles. These ulcers may be found in any part of the alimentary canal, and may be of any shape and of almost any size. The other pathological signs are those of malarial fevers: congestion and ecchymosis of the intestinal mucous membrane, especially in the duodenum and upper jejunum, enlargement of the spleen and of the mesenteric glands, and congestion of the liver. Among the complications met with, hæmor-

Digitized by Google

rhage from the bowels, urinary organs, and other parts is not uncommon. Pulmonary congestion or pneumonia may occur. Jaundice may be present. Purpuric blotches, without scurvy, were seen in some of the cases at Suakim. Rheumatism, sometimes with effusion into the joints, has been observed. Typho-malarial fever may occur wherever malaria is found; imperfect sanitation, or the prevalence of enteric fever, may determine the intestinal symptoms. Overfatigue and excitement are predisposing causes. Typho-malarial fever is not communicable from person to person. It is probable that the fever of Gibraltar, Malta, and the Mediterranean may sometimes be of the nature of typho-malarial fever. The author's experience was gained at Suakim, where malaria in other forms is also met with. Much difference of opinion exists as to what cases should be included under the term "typho-malarial fever." Dr. Squire proposes that the term should be restricted to malarial fevers which in their symptoms closely simulate enteric fever, and that those cases should be excluded which are found post mortem to have the pathological appearances of enteric fever. Temperature charts illustrating the cases were exhibited.

In the discussion which followed, the President, Drs. Hunt, Magill Dwyer, Phillips, and Buchanan took part.

CAMBRIDGE MEDICAL SOCIETY.

A MEETING of this Society was held on Nov. 5th, Dr. J. B. Bradbury, President in the chair.

Pseudo-Hypertrophic Paralysis.—Dr. BRADBURY showed a boy, aged twelve, from Castle Hedingham. Two first cousins were said to have died with this disease. The patient was always well and active before the present illness, which was first noticed in 1881. A tendency to fall down frequently when running down hill was observed, and his legs had been gradually getting weaker, so that he was unable to get off the floor when in a sitting posture. He suffered from nocturnal incontinence of urine nine months ago. His intellect has gradually been getting weaker, and his eyesight has been failing for the last three months. He is said to have had large calves since birth. His appearance is fairly healthy, but he complains of weakness in the legs, and pain in the back on sitting up. His calves and buttocks appear large, and he walks with a swinging movement of his body from side to side. When placed on the floor he has great difficulty in getting up, and pulls himself up with his hands or climbs up his thighs in the characteristic fashion. He stands on his toes with his heels off the ground, and the abdomen arches forwards. Some of the muscles are atrophied —namely, the deltoids, erector spinæ, latissimi, and chondro-sternal portion of pectorals; and the gastrocnemii and latissimi do not react to the faradaic current. Sensation is good, but the tendon reflexes absent. Optic discs appear normal, but there is slight internal strabismus when reading. Urine normal.—Mr. MARTEN showed for Dr. MacAlister a boy, aged ten, who was suffering from the same disease.

General Sarcomatosis; Death from Acute Myelitis.—Mr. LAURENCE HUMPHRY related the case of a gardener, aged nineteen, single, who was admitted into Addenbrooke's Hospital on July 14th, 1886. He had always enjoyed good health until the present illness, and there was no history of heritable disease in the family. The present illness commenced about the beginning of June, 1886, with pain in the loins and weakness in the legs; he had to give up work, but was able to walk about. The patient on admission was pale and weak, and had evidently lost flesh; he complained of aching pains in the knees and hips. The evening temperature was 102°, the morning 98°, and there were slight sweats. In the submaxillary region on the right side was a freely movable swelling about the size of a walnut, which he had hardly noticed. The muscles of the legs were small and flabby, but there was no loss of sensation, and no swelling of the joints. The patellar reflex was normal, and slight ankle clonus could be obtained. The urine was normal, and there were no physical signs of disease in the chest. On July 17th, four days after admission, the legs became suddenly numb and all motor power in them was lost; the urine was retained, and had to be drawn off by the catheter. A few hours after he suffered from severe girdle pains at the level of the umbilicus. On July 19th the girdle pains were subsiding, there was a zone of hyperæsthesia at the umbilicus, and more or less complete loss of sensation from this downwards. Tendon reflex gone; plantar reflex absent. Cremasteric delayed; epigastric present. The bowels acted unconsciously. The symptoms now all pointed to sudden compression of the spinal cord and rapidly ascending myelitis. During the day a crop of subcutaneous sarcomatous nodules appeared on the front of the abdomen and chest, with flat tops and a surrounding zone of redness. There was copious sweating, and the temperature varied from 98° in the morning to 104° in the evening. On the 20th a bedsore developed over the sacrum and rapidly enlarged. The muscles of the lower limbs wasted rapidly, and had lost their electrical reactions. On the 22nd there was weakness in the arms, and the intercostal muscles were paralysed. The subcutaneous nodules were increasing in number, and extended to the scalp, but there were none larger than a sixpence. The tumour in the neck had increased considerably. The patient became gradually weaker and more drowsy during the next fortnight, the bedsores rapidly increased, the urine became offensive, and he died on August 18th.—Mr. J. GRIFFITHS gave the account of the necropsy. The tumour in the neck was beneath the sterno-mastoid muscle, and was sarcomatous, of the small round-celled variety. The dura mater of the brain presented on its outer surface very numerous flattened growths of small size, situated for the most part along the course of the longitudinal sinus and slightly adherent to the inner surface of the skull. There were small nodular growths also on the inner surface of the dura mater in front of the fissure of Rolando. On the inner surface of the seventh, eighth, and ninth dorsal vertebræ there was a mass of new growth extending to the outer surface of the dura mater and attached to it. This was so thick as to produce evident compression of the corresponding part of the cord. In the rest of its extent the spinal dura mater was free from growths. The spinal cord below the mid-dorsal region distended its membranes, and below the seat of compression was soft and granular-looking. In the upper dorsal region the softening only involved the central part of the cord, and there was a focus of softening in the lower cervical region. In the upper part of the dorsal region and throughout the cervical the postero-median columns and direct cerebellar tract showed commencing degeneration, and in the cervical region, in addition, the tract of Gowers showed the same change. In the medulla, just above the decussation of the pyramids, there was a small band of degeneration laterally at the external border, and tracing this upwards it gradually spread outwards into a thin band and became lost. There were small secondary nodules on the pleura and pericardium. In the kidneys were small secondary growths, chiefly in the cortex; and in the medulla were numerous small abscesses, surrounded by well-marked congestion. The ureters and pelves were thickened and inflamed. The bladder was thickened, and the inter-muscular connective tissue much increased. The small abscesses in the kidneys contained micro-organisms, and minute embolic abscesses were found commencing in the liver and wall of the heart. The vessels supplying the softened area in the cervical region were found to be plugged with the same bacteria. All the secondary growths and subcutaneous nodules had the same structure as the tumour in the neck. The thymus gland was not enlarged.

Death following soon after Washing out Dilated Stomach.—Mr. MARTEN brought forward the case of a patient who was admitted into Addenbrooke's Hospital, under Dr. Bradbury, for stricture of the pylorus. He was forty-eight years old, and seven years previously had been an in-patient, with symptoms of pyloric ulcer. His stomach was now much dilated, and he suffered from flatulence, vomiting, pain, and increasing weakness. He vomited large quantities of frothy fluid, containing sarcinæ. Ten days after admission it was decided to wash out the stomach. Soon after passing the tube into the stomach the patient became very faint, so it was withdrawn. About two hours afterwards he complained of stiffness in the jaws, with inability to open the mouth, and rigidity of the arms, which were strongly pronated and flexed, the thumbs being turned on to the palms. The patient was conscious, and sweated profusely. The rigidity spread to all the muscles of the limbs and trunk, and the temperature rose to 103·4°. He became pulseless and livid, the temperature rising to 107·2° before death, which occurred six hours and a half after washing out the stomach. Post-mortem examination showed a simple stricture of the pylorus, with the scar of an old ulcer, and a much-dilated

Digitized by Google

stomach. There was no injury or abrasion of the mucous membrane. The other organs were healthy, and no lesion of the brain was discovered.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Nov. 25th, 1886, Dr. Cleaver, President, in the chair.

Large Thrombus of Right Labium.—Mr. W. M. JONES reported this case, which he was called to see about six hours after labour in a young primipara. He opened it and evacuated more than a pint of clot, and applied carbolic dressings and pressure. Severe eclampsia and suppression of urine followed, but the woman made a good recovery. There was slight suppuration, but in a fortnight's time the wound had quite healed, leaving the parts in a normal state.

Poisoning by Cocaine.—Mr. KELHAM related this case. A man aged thirty took 4½ grs. of hydrochlorate of cocaine in solution by mistake. In twenty minutes he was seized with severe pain in the stomach, thobbing of heart, loss of eyesight and of power in the legs, with incoherence of speech and confusion of ideas; no unconsciousness. Severe vomiting came on with cramps in the stomach and legs, very profuse perspiration, intermittent action of the heart, cyanosis of the face, and feeling of suffocation; then severe prostration, shivering, and coldness of the skin. The severe symptoms passed off in about three hours, but the prostration and vomiting lasted all next day. Thirty-six hours after taking the cocaine he began to lose taste, and had a leathery feeling in the mouth and tingling of the fingers. The treatment consisted in emetics and stimulants.—Remarks were made by Mr. Snell, Dr. Roberts, Mr. Jones, and Mr. Pye-Smith.

At the meeting on Dec. 9th Dr. Cleaver again presided, and the following cases were narrated:—

Biliary Calculi.—Mr. PYE-SMITH exhibited the morbid specimens and related the notes of a case of biliary calculus, which had lodged in the neck of the gall-bladder of a woman aged forty-two. The right leg had become gangrenous and had been amputated, but the patient slowly sank. He also showed a facetted gall-stone, passed per anum, from a patient who had presented signs of abscess of the liver or bile passages, and who had for some days acute intestinal obstruction, and had since coughed up suddenly a quantity of pus coincidently with shrinking of the abscess and the development of a pleuritic rub on the left side. The patient, a man aged sixty-three, was now convalescing.

Locomotor Ataxy.—Mr. GWYNNE gave notes of the case of a woman aged forty-seven, in whom the patellar reflexes were exaggerated. Girdle pains were present, with frequent micturition, impaired sensation, and incoördination of movement. Dr. Gwynne explained the symptoms by supposing disease of the lateral columns to exist; and while the reflex loops in the posterior columns were more or less affected, the disease was probably mainly centred in the groups of cells, which by their connexions preside over coördination of muscular actions.

Locomotor Ataxy (Acute).—Dr. PORTER showed a patient suffering from ataxic symptoms and diminution of muscular sense in both upper and lower extremities, and affection of speech of the same character, coming on rapidly within four months. The patellar tendon reflex was diminished. There was no paresis, wasting, or sensory disorders. The early symptoms had been stiffness, rather than pain, in the knees, feet, and shoulders, with gastric irritability, nausea, and occasional vomiting. There was no history of lightning pains. The pupils were equally dilated, and irresponsive both to light and accommodation; discs atrophic. Sexual power had disappeared completely. Dr. Porter considered the case to be of the nature of locomotor ataxy as regarded the symptoms, but too acute for sclerosis, and somewhat irregular. Although he could not obtain any history or evidence of syphilis, he thought it might be of that nature, and was treating the patient with large doses of iodide.

The immediate Cause of Death in Malignant Cases of Fever.—Dr. C. H. WILLEY, of the Borough Fever Hospital, in reading this paper, said that the cases under consideration were those of scarlet fever and small-pox, in which unconsciousness and death ensued at an extremely early stage. The pathology of this condition has not been explained. The conclusions to which Dr. Willey had arrived were based on clinical observations and post-mortem examinations in twenty-five of these malignant cases. The chief factors in the investigation appeared to him to be that the fatal symptoms in each case were those of a rapidly failing circulation, and that after death the chambers of the heart, and particularly the right ones, were completely filled with white, jelly-like clot, which was, he said, clearly of ante-mortem formation. The failure of the circulation ensues (particularly in small-pox cases) with great suddenness; and the question arose, Was this failure or the thrombosis the primary condition? Evidence from the main symptoms and from such invariably accompanying ones as pulmonary œdema and copious diarrhœa, Dr. Willey said, goes to show that failure of the circulation is the primary cause of death; and, further, that not only is the heart paralysed, but also the entire arterial system; in fact, that an entire collapse of the blood-pressure throughout the vascular system is brought about with more or less suddenness by a functional failure of the sympathetic nervous system, governing as it does the cardio-motor and vaso-motor functions. The pulmonary œdema and the profuse intestinal flux are due to the same cause: they are undoubtedly associated with a greatly diminished blood-tension in the arterial system.—Remarks were made by Mr. Walker, Dr. Gwynne, Mr. Baldwin, Dr. S. White, Mr. James, Dr. S. Roberts, and Mr. Pye-Smith.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AN ordinary meeting was held on Dec. 3rd, Dr. C. S. Smith, President, in the chair.

Supra-pubic Lithotomy.—Mr. MCGILL read a paper on three cases in which he had recently operated. In the first, the patient, aged forty, underwent lithotomy seven years before. Three stones, weighing respectively 3 oz., 2 drs., and 10 grs., were extracted. Urine passed by the urethra on the twentieth day, and recovery was complete. In the second case the stone weighed ½ oz.. The wound was healed on the tenth day. The patient was aged. In the third case there was considerable doubt as to whether a stone was really present, but eventually a calculus weighing 10 grs. was removed. The bladder wound was stitched up, but the urine escaped. Mr. McGill pointed out that there was a singular coincidence between the mortality after lithotomy in ancient and modern statistics; and this was borne out by the accounts kept in the Leeds Infirmary during the last fifty years. According to the Norwich statistics, 56 per cent. of cases when the stone was over 3 oz. proved fatal, and 25 per cent. in cases over forty. He thought the operation contrasted very favourably with the lateral operation in facility of performance, convenience in thoroughly exploring the bladder, and in the risk of hæmorrhage, and that shortly the operation would completely take the place of the older method. With regard to lithotrity, he pointed out that there was a return of the stone in one in seven cases according to Sir H. Thompson's statistics.—Mr. WHEELHOUSE pointed out that lateral lithotomy held its ground in former times because of the rapidity with which it could be performed in the pre-anæsthetic period. At one time median lithotomy threatened to monopolise the field; but he held now that with a small stone and a healthy bladder lithotrity was to be preferred, but with a large stone and an aged patient the supra-pubic incision was the best.

Experimental Researches respecting Pasteur's Anti-rabic Method.—Dr. HIME gave an account of some experimental researches he had lately conducted on this subject. (See THE LANCET, Dec. 11th, 1886.

Toxic Effects of $\frac{1}{100}$th of a grain of Sulphate of Duboisin. Dr. CHADWICK related a case where this amount of the drug, instilled for examination of a senile cataract, produced a state of delirium lasting many hours, leaving the patient totally unconscious of what had occurred. There was great muscular weakness, and many strange actions were performed. It was suggested that the susceptibility to this drug reached its maximum in old age, and that the similarity between the symptoms and those of senile atrophy, popularly known as "softening of the brain," might suggest that its action was by causing spasm of the cerebral arterioles, and might indicate a possible liability to that form of pathological change.—Dr. MAJOR said the symptoms closely resembled those he had noticed in a medical friend, who took for experimental purposes a large dose of hyoscyamine

Digitized by Google

being characterised by strange antics, with curious unreasonableness. He attributed much of the effect to delusions of vision.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Friday, Dec. 17th, Mr. Hatherly, President, in the chair.

Mr. E. POWELL showed a case of Cervical Rib in a woman, the patient of Dr. Handford.

Mr. PRYCE brought forward a young woman, aged twenty-three, who presented the condition of Cervical Rib on both sides of the neck.

Mr. PRYCE also exhibited the following specimen:—Pyelo-nephritis, Inflammation of Right Ureter, Cystitis and Caseous Deposit in the Prostate, probably of a tubercular origin, from a man aged twenty-four, who during life had suffered from intermittent attacks of hæmaturia, great prostration and loss of flesh; likewise a water-colour drawing of the same by Mr. Geraty.

Dr. WHITELEGGE read a paper on Disinfection. The experiments of Koch, Klein, and Parsons were summarised, and shown to disprove the efficacy of almost all the ordinary chemical disinfectants. Some were practically useless—sulphate of iron and chloride of zinc, for example; while others were mere deodorants, without any true disinfectant action. Some, again, were antiseptics only—that is, they held in check the multiplication and growth of germs for the time being; and many of the true germicides were employed in such insufficient strength or duration of exposure that their action must necessarily be *nil*. The only trustworthy chemical disinfectant or germicide at present available seemed to be mercuric chloride. Of aerial disinfectants or fumigants, chlorine was by far the most satisfactory, and, unlike sulphurous acid, could at least be relied upon to disinfect all exposed surfaces, but the practical difficulties attending its efficient use were very great. No fumigant could disinfect bedding or clothing. Articles such as blankets, which could not be boiled without injury, should be disinfected by steam, in a special apparatus. Although hot-air disinfecting stoves had been of the utmost service in the past, they would not deal with such refractory organisms as spores of bacilli, even if exposed freely, without injury to fabrics. Finally, it was pointed out that, with the exception of boiling and treatment by mercuric chloride, no real disinfection was possible by unskilled persons in private houses; and, further, that isolation must be regarded as the sheet-anchor in dealing with infection, its importance becoming more and more manifest as we realised the futility of ordinary disinfection. In private houses it was rarely possible to maintain isolation for more than the commencement of the long and tedious period of still infectious convalescence.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

THE annual meeting of the members of this Association was held on Dec. 21st at the Town Hall, Bradford, Mr. S. W. North (York) presiding.

Dr. J. M. Wilson (hon. secretary) read the report of the committee, which was adopted. Mr. North having intimated his desire not to seek re-election as president, Mr. Roberts moved: "That the cordial thanks of the Association be given to Mr. North for the valuable aid he has given to it during the eleven years he has been President." The resolution was seconded by Dr. Giddings, and carried. Dr. T. W. Hime (Bradford) was elected president, on the motion of Dr. Giddings, seconded by Dr. Edwards, and supported by Dr. Britton and Dr. Byles. On the proposition of Dr. Cameron, Mr. North, Dr. Giddings, and Dr. Britton were elected vice-presidents, Dr. J. M. Wilson (Doncaster) was re-elected hon. secretary, and Dr. Bruce Low hon. treasurer.

Dr. J. M. WILSON read a letter from Dr. Alfred Hill (Birmingham), who said he had felt for some time that it would be to the advantage of the whole body of the medical officers of health if they were to form themselves into one society; and Dr. BRITTON moved, and Dr. HIME seconded, the following resolution: "That this meeting, having heard the communication of Dr. Hill on the subject of the provincial Societies of Officers of Health joining the Central Association in London, desires to express its concurrence in his views, and that we appoint the president, ex-president, treasurer, and secretary as a subcommittee to arrange the details." The motion was carried.

Dr. J. M. WILSON read a paper, giving an account of an Outbreak of Diarrhœa caused by the emanation of noxious gases from tide-locked sewers.—Dr. BYLES called attention to the extra duties required of medical officers of health under the Cowsheds and Dairies Order, by which the inspection of these places has been transferred from the county constabulary to the local authorities in each district. He said he foresaw that if they were to carry out the duties imposed upon them by the new Order they would have a largely increased amount of work to perform, and a deal of it of a dirty, disagreeable, and dangerous character. It looked as if medical officers were about to be called upon to perform the duties of veterinary surgeons. Another matter for medical officers to consider was as to how they were to be remunerated for their services.—Dr. HIME said that it had been his practice in Bradford, when a person made an application for a licence, to go to the premises and see if they were suitable. The power they possessed over dairies and cowsheds was very inadequate, and they were sadly in want of stringent bye-laws for their regulation.—Dr. BRITTON said that he had received no information on the subject, either from the Local Government Board or his own board, and until he did he should not feel called upon to act in the matter. In his opinion the examination of dairies and cowsheds ought to be left in the hands of the nuisance inspector.—Dr. J. M. WILSON remarked that his inclination would be to superintend the work, which should be done by the nuisance inspector. As medical officers, they ought not to forget that they were advisers on matters of health to sanitary authorities. After they had made themselves acquainted with the requirements of the new Order they could consider the question of remuneration.—The CHAIRMAN said it was part of his duty as a medical officer to inquire into the causes of disease within the area of his local authority, and he had never hesitated to go into dairies and cowsheds to see whether they were kept in a satisfactory manner.—Dr. SCOTT believed that the new Order would involve very little extra labour upon medical officers.

Dr. HIME afterwards exhibited a Pasteur-Chamberland filter, and the Secretary a sample of peat dust for use in earth-closets.

Reviews and Notices of Books.

General Paralysis of the Insane. By JULIUS MICKLE, M.D., &c. Second Edition, enlarged and rewritten. London: H. K. Lewis.

THE second edition of this exhaustive monograph is to a large extent a new book, contains nearly double the amount of matter presented in the first edition, introduces many new points, and also treats old subjects on entirely new lines.

With regard to the nature of general paralysis of the insane, the chapter on Pathology considers this from every point of view. This chapter has been entirely rewritten, and deserves the most careful perusal by the student. It is here stated that, with regard to the essential nature of the disease, it may be a mere complication of insanity, or, what is more likely, a distinct and special form of mental disease. It may be a disease with and also without insanity; it may be of an inflammatory or of a degenerative nature; its seat may be in the brain, the cord, or the sympathetic nerves; but its point of departure appears to be almost invariably from the cerebral cortex.

Let us now briefly glance at the novelties most conspicuous in the new edition of this valuable work. Hallucinations, formerly declared not to exist in general paralysis, are found by the author to be occasionally vivid, though at other times by no means obvious. Fifty-five out of a hundred cases possessed them. The handwriting becomes illegible and shaky, Bacon's illustrations and Blandford's recognition of the omission of words being here mentioned. Athetosis and choreiform movements frequently follow epileptic attacks, and reflex activity becomes lowered later on. Anosmia, with wasting of the

Digitized by Google

olfactory bulbs, is present in chronic cases, and here the author's experiments with onions, camphor, and pepper are quoted. This is often attended with a defect of taste, auditory hyperæsthesia, and sometimes deafness. Tactile sensibility in the last stages is abolished, yet hyperalgesia and neuralgia may coexist. Cutaneous illusions, such as blows, kicks, or lightning pains, are now complained of, and are connected probably with some spinal disorder.

The remarks on bedsores are very complete. These chiefly attack the sacrum, trochanters, heels, ankles, knees, elbows, toes, vertebræ, scapulæ, and even the occiput. Surgical measures are occasionally called for, as when pus begins to burrow internally amongst the tissues. Hæmatoma auris usually begins in the fossa of the helix, but it is not peculiar to general paralytics, as it has been seen in the ear of a prize-fighter (Sutherland), and amongst schoolboys from violence at football (Farquharson).

Dr. J. G. Davey seems to have been the first observer of bone disease in insanity (1842), and Dr. J. W. Ogle has drawn attention to experiments in which the interference with nerve-supply brought on hyperostosis. Dr. Ormerod has found the ribs in general paralytics dark, wet, greasy, and brittle, with small Haversian systems. Drs. Clouston and Williams have noted that these ribs break more easily than those of a healthy man, which Dr. J. L. Rogers considers due to the diminution of calcic salts. There are, moreover, special arthropathies in this disease, which are here illustrated by cases.

In the blood of the general paralytic there is obviously a spanæmia in the last stages. Thakrah and Hittorf observed its hydræmia; Michéa found the serum solids increased; A. J. Sutherland and Bence Jones found a diminution of albumen; and H. Sutherland believed that an absence of rouleaux, together with an increase in the colourless corpuscles, were conditions almost peculiar to general paralysis; and the researches of Voisin, Brunet, and lately of Macphail, agree with these results.

That the temperature in general paralysis is increased in the maniacal and apoplectic attacks has been remarked by the author and by Meyer; Dr. Clouston has also observed that the average evening temperature is always above that of the morning. The pulse in the early stages is full and hard, and the second sound of the heart accentuated, the author's remarks here coinciding with those of Dr. Bevan Lewis. Generally speaking, the average evening temperature, pulse, and respiration are above the normal. Sometimes the pulse goes up to 80, 90, and 100, and in other cases descends to 64 and 66. Dr. G. Thompson's able remarks on the sphygmographic tracing of the pulse in general paralysis, which he considered indicative of spasm of the arteries, are denied by the author. In 1877 the author placed on record some examples of unilateral sweating in general paralysis, affecting one side of the face and head.

The terminations of general paralysis may be death, chronic mental disease, or (?) recovery. The modes of death may be exhaustion, septicæmia, pyæmia, spinal meningitis, pulmonary or abdominal diseases, such as pneumonia, phthisis, diarrhœa, nephritis or cystitis, hæmorrhages, epileptiform convulsions, apoplectiform attacks, embolism, or choking by food. Suicide is rare, but rib fracture is sometimes a cause of death. In a large share of cases several factors are concerned.

In the chapter on Diagnosis we have these additions: The distinctions between general paralysis and acute alcoholism with agitation, delirium tremens, melancholia with stupor, chronic insanity, secondary dementia, and poisoning by strychnine, bromides, and iodide. Other diseases simulating general paralysis have also been described at greater length.

Statistics.—Dr. Mickle has computed that of the total admissions in England and Wales of insane persons during the past four years—viz., 26,658 males and 27,984 females, or a total of 54,642 persons—3374 males and 910 females were general paralytics, or a total of 4284 persons. The average proportion per cent. of the number of general paralytics of each sex admitted to the total number of patients of each sex admitted during these four years was 12·65 per cent. for the males and 3·25 per cent. for the females, or 7·8 of the total admissions of both sexes.

Under Morbid Anatomy the author has enumerated his observations most minutely. The adhesions were marked or extreme in 30 per cent. of all cases of general paralysis. The brain-weights of Crockley Clapham are here quoted, but, curiously, the average weight of the entire encephalon for all classes in society of males is 44·01 oz., whilst the military standard is 44·15 oz. Additions have been made to the remarks concerning the state of the heart, lungs, and kidneys in general paralysis.

The microscopical appearances are given fully. The brain may be first affected, the brain and cord may be attacked simultaneously, or the cord may be first affected, which is rare. We must, however, draw attention to Tunzek's work on the atrophy of the nerve-fibres of the cerebral cortex; Baillarger's and Horn's ideas that general paralysis can be caused by propagation, as from simple tabes dorsalis; Sir Crichton Browne's and Blandford's theories that general paralysis is a disease of inflammation; Boinet and Poincaré's notion that it is a vaso-motor disorder; and the author's statements that it may be viewed as a meningeal, a spinal, or a neurotic affection. Post mortem the inflammatory theory is constantly upheld, as shown by the opacities, adhesions, coloured skull-cap, and arachnoid cysts so common in general paralysis. Which part is first or mainly inflamed? Some say the meninges, some the cortex, some both, some the cord, and others, again, the cerebro-spinal nervous system.

The chapter on Therapeutics has been rearranged and expanded. The apparently new points here are the remarks upon ergot, physostigma, digitalis, and nitrate of silver. Maniacal excitement may be dealt with by quickly acting purgatives, warm baths, the bromides, veratrum viride, and ether spray to the head. Opiates and henbane are not recommended, and the ill effects of chloral, where contra-indicated, are alluded to.

The chapter on the varieties of general paralysis, and also the illustrative cases have been very wisely curtailed.

As we have said, this manual of General Paralysis is exhaustive. It is a book which must necessarily find a place upon the shelf of every medical man who desires to keep up to the standard of the time, be he physician, surgeon, obstetrician, or psychologist.

Functions of the Brain. By DAVID FERRIER, M.D., F.R.C.P. Second Edition. London: Smith, Elder, and Co. 1886.

THIS work is well known to all who take an interest in the science of neurology, of which the functions of the brain form no small part. It is needless to say anything in praise of the work, the second edition of which is brought well up to the times. No scientific medical man's library can be said to be complete without Dr. Ferrier's book, which contains the records of the author's own work, as well as those of other observers of repute.

Dr. Ferrier is careful to give the different views of authors concerning disputed anatomical and physiological matters, and in places helps the reader to discriminate between opposing or apparently antagonistic opinions. The book is abundantly illustrated, and most of the figures convey in a definite manner the points referred to in the text. The definition of some of the figures is really excellent—Figs. 28 *et seq.*—from sections of the monkey's cerebral cortex, by Bevan Lewis. That the work is well up to date is shown by frequent references to investigations of the past year.

Digitized by Google

Beevor's observation is given that the fibres from the internal capsule and those from the corpus callosum do not interweave with each other in proceeding to the grey matter of the cortex. This is taken from the October number of *Brain* (1885). Spitzka's observations on the Comparative Anatomy of the Pyramidal Tract (Jan. 1886) are also quoted. The work is one of great and peculiar value; for, even supposing that one had at hand a record of all the recent researches into this subject, it would be an exceedingly tiresome and laborious task to cull from the various works all that had been written, say, about the functions of the cerebellum Dr. Ferrier does this for us, and arranges the matter in harmony with his own observations and experiments; so that in the space of sixty pages (174 to 234) we have a connected account showing the present state of knowledge of the subject. It is needless to say more concerning a work which no neurologist can afford to be without.

Transactions of the Society of Medical Officers of Health.

THE volume of the Transactions of the Society of Medical Officers of Health which has just been issued contains several papers of especial interest. A historical account of house sanitation formed the subject of the inaugural address of the President, Dr. W. H. Corfield, who told therein the story of house-drainage from early Roman times up to the present, and who discussed the great advance which has recently been made in legislation affecting the sanitary condition of dwelling-houses. Dr. G. A. Heron contributed an excellent paper on Koch's cholera bacillus, in which he strongly supported the view that the organism described by the German *savant* deserved the position which he attributed to it, and urged the arguments which are afforded by the effect of this bacillus on cultivating fluids. Professor G. Bischof also read a paper on Koch's gelatine-peptone water test, which appears in the same volume. As a result of much experimental work, Professor Bischof has come to the conclusion that the test is untrustworthy, and that the number of colonies ordinarily found in water has no necessary or invariable connexion with wholesomeness or pollution; but he admits that with further development the test may have a value which it does not at present possess. A very original paper by Mr. Eassie, on the waters derived from the Bagshot beds considered as drinking supplies, discusses the impurities contained in these waters and their cause. After careful investigation, Mr. Eassie concludes that although many of the Bagshot beds are capable of furnishing a supply, more or less abundant, of water for dietetic purposes, yet he says there are other strata in the same formation which secrete and supply waters unfitted in their natural state for potable use. He therefore argues that every supply of water derived from the Bagshot series, and especially from the middle and lower beds, should be carefully analysed, and the deeper the source of supply the greater the need for analysis, for the reason of want of nearness to oxidating powers. Other papers of importance to health officers are published with those to which we have referred: the recommendations of the Royal Commission on the Housing of the Working Classes as affecting the status of the medical officer of health was the text of a paper by Dr. Seaton; the suction of sewer gases into service-pipes conveying drinking-water, by Dr. Swete; the protection of milk-supplies from contamination, by Messrs. Wynter Blyth and Alfred Spencer; regulations as to lodging-houses were discussed by Mr. Lovett; and the sanitary condition of poor districts in the metropolis, by Dr. Parkes. We note with satisfaction the development of this Society and its increasing powers of usefulness to medical officers of health in all parts of the country. The appointment of Dr. Alfred Hill of Birmingham as president, following that of Dr. C. E. Saunders as one of its secretaries, is ample evidence that the work of the Society has not more relation to sanitary work in the metropolis than in other parts of the country.

Indian Veterinary Manuals. 1. The Elephant. By JOHN HENRY STEEL, V.S., A.V.D. Madras: W. H. Moore. Pp. lxiv-100. With many Illustrations. 1885.

THIS is the first of a series of manuals that promise to be of much use, being written in a semi-popular style, yet containing a large quantity of not readily accessible information. Elephants have been used in Asia and Africa from very remote periods as animals of war, as by the Carthagenians, Romans, and Persians; and in old times, when these could be protected by some sort of defensive armour from such implements as arrows, stones, and the like, they may have proved serviceable, their huge bulk and impressive appearance when in long ranks striking terror into those who were not accustomed to them, or who had, perhaps, never seen them. But Mr. Steel remarks that their use is becoming much restricted. The elephant's terror of firearms renders his great bulk and his great strength terrible rather to friends than to foes, and in the Burmese wars formidable lines of these animals have been put to rout by small bodies of cavalry. Then, again, their weight renders it difficult to transport them from one place to another. Their keep is very expensive, their original cost considerable, and they are liable to various diseases. Still, elephants are extremely useful in carrying the impedimenta of war, including not only tents and baggage, but cannon; whilst they can often free in a few minutes a gun or a waggon fixed in the mud, which would require much time if ordinary means were used. The work is divided into two parts, both of which contain much highly interesting reading. The first, or introductory part, deals with the natural history of the elephant and his use in modern armies, whilst the second part treats of his diseases. We commend the perusal of this book to all who are interested in this remarkable quadruped.

THE EFFECT OF A DIET WITHOUT LIME UPON THE TEETH.

To the Editors of THE LANCET.

SIRS,—Far be it from me to throw cold water upon any honest experimentation, especially upon the work of an observer who has won his spurs, as Dr. Miller has, by years of careful experimental work in the field of bacteriology. Still, it appears to me that more weight has been attributed to the three experiments upon the feeding of dogs on a diet deprived of lime salts than is legitimate, and, indeed, than Dr. Miller himself claims for them. He used for analysis, at intervals, two upper canines and one lower, or *vice versâ*. Dr. Galippe has shown that the specific gravities (which correspond pretty closely with the chemical composition) of corresponding teeth on the two sides of the mouth differ, as do those of the upper and lower jaws, in the same individuals. Dr. Miller's results show only small differences in the percentage compositions of the teeth during the period of his experiment, and these differences are discordant. It need hardly be pointed out that an average drawn from nine discordant analyses has not the faintest significance. If any inference as to probabilities is to be drawn from so small a number of cases, the one which suggests itself to me is that the feeding was productive of no traceable result at all upon the teeth. It is also said that it is a fact familiar to dentists that the teeth of an individual undergo alterations in character as to density &c. at various periods during life. Everyone knows, of course, that caries advances with very varying rapidity at various periods; but it is a mere begging of the question to assume that this is due to alterations in the teeth and not to alterations in their surroundings. This matter is, however, too wide a one to enter upon in this place, so I will only say that, personally, I have never seen any case lending support to this idea.—Yours faithfully,

Jan., 1887. CHARLES S. TOMES.

THE LANCET.

LONDON: SATURDAY, JANUARY 8, 1887.

THAT there must soon be a considerable reform in all that relates to the office of coroner in this country cannot be doubted by those who have paid any attention to the subject. The office is one of the greatest antiquity, but, unlike some other ancient institutions, it does not admit of the sweeping reform of abolition. On the contrary, it is a most important office, which in the very nature of things must, reformed or unreformed, endure as long as humanity itself; for it must always happen that deaths will from time to time occur under circumstances calling for an inquiry into their cause. We cannot hope for a time when there shall be no sudden or violent deaths. It follows therefore, that there must be some official appointed to make inquiry into the cause of all those deaths which from the surrounding circumstances demand it. It is true that in cases where a charge of murder or manslaughter is made there is an investigation before the magistrate; but while this has the inconvenience of a double inquiry, it is no argument, as some contend, for abolishing the office of coroner. There are many cases in which a death has occurred the cause of which is unknown, and can only be ascertained by a searching inquiry into all the circumstances, including medical evidence and a post-mortem examination, but which do not go beyond the coroner's court. As an illustration of this, we may mention the case which occurred more than forty years ago, and was generally known as the "Hounslow flogging case." The late Mr. THOMAS WAKLEY, the founder of this journal, held an inquest and made a searching inquiry into the death of a soldier who had died soon after receiving the punishment of flogging. Although no specific charge against any individual was involved in the verdict of the jury, and though the case did not go beyond the coroner's court, the inquiry was one of the most important ever held, and led to the abolition of flogging in the army. Other instances might be given. It is plain, however, that there must be a preliminary inquiry into the cause of some deaths, and even in countries where there is no coroner's inquest there is a modification of it, to which we shall allude presently. It being clear, therefore, that the office of coroner must remain, What are the reforms needed? To answer this let us see what are the defects of the present system?

The principal one is a total want of uniformity, from the mode of election to the close of the coroner's career, whether that be with his life or with his office. Judges, recorders, and magistrates are appointed with some regard to uniformity; so are sheriffs. But town and city coroners are elected by the local municipal council, those of Oxford and Cambridge by the University, and the Admiralty coroner by the Crown or Lord High Admiral. There is still another mode [illegible]. The county coroner is elected by the freeholders. [illegible] MACDONALD, M.P., one of the candidates at the late election of coroner for the eastern division of Middlesex, intends to bring in a Bill to amend this mode of election, and will no doubt be heartily supported. Passing on to the qualifications for the office, we find still the same want of uniformity. No peculiar qualification is now required, though in HAWKINS' "Pleas of the Crown" the author seems to express an opinion that the persons chosen, though not knights, must be "of good substance and credit." Practically, however, the office is now held chiefly by barristers, solicitors, or members of the medical profession. Of a total of 286 coroners whose qualifications are stated, 238 belong to the legal and 48 to the medical profession—a disparity which cannot be justified in these days. We have always contended that, as the primary duty of a coroner is to ascertain with the aid of a jury the cause of death, such duty comes more within the province of a medical man than of a lawyer. The old objection to a medical coroner, that his duty is not so much to ascertain the cause of death as to find out who caused it, never had any real foundation, and at the present time is wholly untenable. It will not strengthen the case for legal coroners to argue, as some do, that they understand evidence and legal formalities better than medical men, for inquests held even by lawyers have been quashed for legal informalities. And that the average solicitor is by no means well posted up in the law of evidence is well known both to judges and counsel, the depositions of legal coroners having frequently been complained of as being most unsatisfactory. Besides all this, there is the most formidable objection of all to legal coroners, that the duties are extremely repulsive to the average lawyer, and the office does not attract those who are likely to be successful in their profession. On the other hand, the most repulsive part of the duties—that of viewing the bodies and taking medical evidence—is what most medical men have been well trained to, while the office has attracted and still attracts medical candidates with the highest qualifications. Nothing can be more trying or disheartening to medical witnesses than the impatience with which their evidence is too often received by legal coroners. The late CHARLES DICKENS was a severe critic of our profession and its members, but in the serio-comic narrative by the "Uncommercial Traveller," "On a Coroner's Jury," he gracefully alludes to "the Coroner who was nobly patient in receiving the evidence, and humane: he was the late Mr. WAKLEY..... for which," he adds, "I ever afterwards felt grateful to him, as I do now to his memory." Continuing the defects of the present state of the law, county coroners are appointed for life, and cannot resign, like most officials. An antiquated procedure, the writ *de coronatore exonerando*, has to be obtained, and by this means only can a county coroner be relieved from his duties, old age and infirmity notwithstanding. Again, on the death of a coroner his deputy cannot act; the duties must be performed by another coroner at considerable inconvenience both to himself and others

But where uniformity is most wanting is in the manner in which inquests are held. Coroners are paid by fees, upon a three years' average; thus there may be an inducement to multiply inquests. Some coroners hold inquests in every case of sudden death; others exercise a discretion. Some require the jury always to view the body; others have dispensed with this legal requirement in a few

Digitized by Google

cases, thus rendering the inquest null and void. Some coroners have a beadle or officer; others depend on the police for information of deaths requiring an inquest. Some, especially medical coroners, require medical evidence at almost every inquest; legal coroners dispense with it as much as they can to save the rates. All this confusion arises partly from the very antiquated statute under which coroners still act—the 4th EDWARD I., stat. 2,—a statute passed six centuries ago; partly also because the sources whence the coroner derives his information are various. He may learn it from his beadle, from the police, from a medical practitioner, from a registrar of deaths, or from a relative or friend of the deceased.

The obvious remedy for most of these evils is to provide for greater uniformity, care being taken that the new system shall possess all other needful reforms. In Scotland, where the duties of coroner are performed by the procurator fiscal, complaints have arisen that many cases which ought to be inquired into are withheld from him, and we have had a recent instance of the defect of the Scotch system in what was known as the Carlisle poisoning case. The body of the unfortunate woman, who was poisoned by some ham which she had eaten at her own wedding breakfast, was removed from Edinburgh to Carlisle for burial without the knowledge of the fiscal authorities. Hence arose a deadlock when the full particulars were fully known. The Edinburgh Procurator Fiscal could not act, as the body had been removed out of his jurisdiction; the coroner for Carlisle could not act, because the death occurred beyond his district. It is, moreover, a source of complaint that the inquiry of the Procurator Fiscal is a secret one. A similar secret mode of inquest prevails in the Channel Islands. In the Isle of Man inquests are held by the high bailiffs of the four principal towns; the inquiry is public and with a jury. In Ireland the system is the same as in England, though the proportion of medical coroners is, we believe, greater than in England and Wales.

Coroners should be permitted to resign at a reasonable term of notice, and deputy coroners should act on the death of the coroner until his successor be appointed. The claims of medical candidates should be duly considered, since experience has shown that medical coroners have discharged their duties with the greatest satisfaction, and to the interests of all concerned. The Births and Deaths Registration Act should be further amended, so far as deaths are concerned. It should be required that notice of every death be given to the registrar within a certain interval after death, and that all violent or sudden deaths be notified directly to the coroner of the district. More stringent regulations are required as to the burial of still-born infants, as recently noticed in these columns; printed forms of certificates of still-birth should be issued to all medical practitioners, and forms of declaration to all certified midwives. The rights of general practitioners should be strictly respected; a second medical witness could be called in cases where a criminal charge is preferred against anyone; and preference should be given to skilled pathologists and medical jurists, the general practitioner first called-in making the post-mortem examination in conjunction with the former.

These reforms would ensure considerable improvements, with but little expense or inconvenience to anybody. Other improvements would suggest themselves, and by a little mutual concession, coroners and medical practitioners working together for the common weal, we should get rid of all the defects and abuses now prevalent, and coroners' inquests would become what they ought to be, solemn and searching inquiries.

THERE is a paper in the January number of the *Contemporary Review* by Mme. ADAM, who has long posed as "the enemy" of PAUL BERT, while trying to run with the hare and hunt with the hounds in relation to the movement which BERT is alleged to have inaugurated against the clerical party in France. The doctrine this lady philosopher lays down is that the two castes, the religious and the scientific, should be "equally excluded from all participation in politics." While affecting to cherish an intelligent respect for both Religion and Science, Mme. ADAM holds that the one is necessarily idealistic and the other materialistic, that they cannot possibly be reconciled, and that they must accordingly be manipulated, as elements in the national constitution and life, by statesmen who are neither priests nor scientists, but superior to both. The argument is plausible, and it is effectively stated by the advocate, but the premisses are bad; and when we come to look closely into the facts the inferences must be seen to be fallacious. "The equilibrium of a society," writes Mme. ADAM, "depends on the equal proportion of the scientific and the religious element in it. When the priests tip over the balance on their side, society suffers in its material needs, and is impoverished; when science gets ahead of religion, society grows rich, gives itself up to luxury, and soon becomes corrupt. The men of science sacrifice everything to the play of forces, the acceleration of movement. Reason and logic are the only compass they steer by, and their ideal for the individual is the facing of difficulties and the achievement of success. But in all this, goodness (which is instinctive religion), heroism, self-devotion, the love of one's neighbour, go for nothing." It is very plain that the view propounded, and the starting-point from which this conclusion is reached, are narrow and mistaken. Was there ever a grosser libel on science, particularly the science of Medicine, which is Mme. ADAM'S *bête noire*, than to say that it excludes, nay does not foster, heroism and self-devotion? It is a matter for thankfulness that the doctrine taught has not been turned to worse purposes than that to which Mme. ADAM has striven to apply it—namely, the subordination of facts to theory and the glorification of a particular sort of cleverness at the cost of depreciating the value of true knowledge. The essence of the idea is that "politics consists in government as something apart from the nation governed. It is the *reductio ad absurdum* of the Platonic notion of a bureaucratic system of administration. Mme. ADAM'S fundamental proposition embodies an idea which is at once the pride and weakness of the French system and has run through successive developments of Monarchy, Imperialism, and Republicanism. Statesmanship is regarded as a profession across the Channel. Government is the supposed work of genius. The notion of a State having its affairs administered on constitutional principles, without some constructive ulterior purpose to which

Digitized by Google

everything else is subordinate, is one that has no place in the philosophy of the grand nation. Statesmanship is a function apart from all else, and statesmen compose a class or caste, the highest in the land, and from this order, according to Mme. ADAM, priests and men of science ought to be rigidly excluded because they represent elementary and constituent parts or principles. They may contribute plums to the pudding, but they may not be cooks, and it is for the cooks exclusively to determine how much or how little of each particular ingredient is to be compounded. Now, we directly join issue on this ground, and must take leave to characterise it as an unwarrantable assumption, based on, or excused by, a total misconception of the very first principles of self-government. The bare fact that such a notion is widely tolerated among the thinking classes in France is a proof that her people are not ripe for self-government. The truly intelligent classes among our neighbours, as among ourselves, must see that Mme. ADAM'S idea—which is unhappily the idea of a very large proportion of the more active people across the Channel—is fatal to the realisation of true *liberty*. It involves a transference of power from one section of the "governing caste" to another, the real business classes of the people being systematically denied a share in the control of public affairs. So far from its being true that priests and men of science should be excluded from the government of the State, these classes ought to be duly represented in the governing body. Although we cannot go so far as AUGUSTE COMTE, and affirm "that a State should be governed by men of science," we are very far from thinking with Mme. ADAM that no "falser theory of government ever entered a wise man's head"; and we believe that it will never be well with progressive States until the claims of science to a larger voice in the administration of public affairs is recognised, and allowed to take effect in the formation of Governments and Cabinets.

The phrase "science in politics is politics in science," on which Mme. ADAM seems to plume herself, has no precise meaning that we can discover. She contends it implies "a very bad warping of the mind twice over." Her notion seems to be that the method of inductive reasoning by which the true scientist ascertains his facts and draws and corrects his inferences is inapplicable to the system of government. A nation must not have its affairs administered on natural principles. There must be no attempt to reason from the known to the unknown, or to guide the vessel of State on a course projected on scientific principles. The statesman must, like the poet, be born, not made. He must evolve the schemes of government with which he rules the nation from his inner consciousness or gain them by inspiration. The science of political economy is to minds of the class represented by this gifted lady a crude and pitiable attempt to formulate what ought to be treated as the sublime outcome of genius. It is to the ascendancy of such ideas as these our neighbours owe the fact that there is no distinctly practical and business-like policy underlying their system. They are "a nation of shopkeepers,"—because the commercial classes, which form the backbone of other nationalities, must needs be represented adequately in their [illegible] excluded from the function of statesmanship. When we speak of the commercial classes, we include the whole composite body of producers and manufacturers, and the classes that exercise an active influence on the constitution of society. Among these classes must needs be included the "priests" and ministers, who supply the religious element to the national organisation, and conserve the morals of the people, and the "men of science" to whose enterprise and achievement every branch of industry in these modern times owes its precision and success, and without whom the body politic would be disintegrated in spite of the supreme sagacity of the most gifted order of professional statesmen. PAUL BERT was a medical scientist, and it is against the special class of workers in science he represented that the animosity of Mme. ADAM is particularly directed. Underlying her antagonism to the scientists there is, of course, the anti-vivisection idea. Mme. ADAM is especially aggrieved by the demonstration of the grafting process. She brings it in at every twist and turn in this article, and would seem to have alluded to it in nearly every conversation she had with GAMBETTA or PAUL BERT. It is a "fixed idea" with her, and obtrudes itself so frequently as to break the thread of every argument. We strongly recommend those of our readers who have not read the paper on which we are commenting to do so. It cannot fail to afford them amusement directly, and instruction indirectly. Madame ADAM'S hatred of PAUL BERT—not personally, perhaps, but as a representative man—is as GAMBETTA had the honesty to tell her, "truly feminine."

In one regard Mme. ADAM differs from some other lady agitators—namely, in favouring, or affecting to favour, the idea of religious education. The sort of "religious education" permitted under the *régime* she would establish is not, indeed, likely to be very satisfactory to those who desire religious instruction for the rising generation, but Mme. ADAM'S recoil from the Materialistic School, as represented by PAUL BERT, has been so violent that she is perforce driven back almost, if not quite, into the arms of the clerical party. This is what we mean by saying she has tried to run with the hare and hunt with the hounds in relation to the anti-clerical movement. She throws the whole responsibility of Article 7 of the decrees of March 29th upon PAUL BERT, and then taunts him with wanting "just that element in which his scientific experiments have been wanting too—success." She contends that "you cannot reckon among the assured acquisitions of science discoveries which are neither incontestable nor uncontested." This remark is in itself conclusive evidence of Mme. ADAM'S incompetency to discuss the subject of PAUL BERT'S achievements and failures, or to form an accurate estimate of his work as a whole. She is ignorant of the fact that not a few of the most priceless treasures of science have been found among the ashes of exploded ideas. The very fiascoes of the honest and earnest scientist are more productive than the chimerical dreams of the theorist. Mme. ADAM may be excused for not knowing this, for it is manifest that her acquaintance with even the history of scientific discovery is extremely limited; but she cannot so readily be pardoned for the bad taste of an article which

Digitized by Google

seems to have been indited on the novel and, let us hope, exclusively French idea—*De mortuis nil nisi—malum.*

IT would be interesting to know the number of those who are prevented from visiting our theatres because of their unwillingness to encounter the stifling atmosphere which as a rule prevails in them; and it would, we have little doubt, much astonish theatrical managers if they could realise the amount of hard cash which is kept out of their exchequers by those absentees who weigh the pleasures of the evening against the morning's headache, and arrive at the conclusion that these few hours' pleasure is not worth the price in physical suffering which is paid for it. We are well aware that our pleadings for ventilation may be met by the objection that the theatres mostly fill well, and that this may be taken as an indication that the public is satisfied in all particulars. The success of our theatres—the long runs and the crowded houses—is due, however, in a great degree, to the extension of our railway system, and to the enormous influx of visitors from the suburbs and the distant country, who come to London for their theatrical pleasures, and are willing to brave a few nights of suffocation for the sake of witnessing performances the recollection of which serves to relieve the dulness of the country. It is notorious that many London residents, and notably the professional classes, to a large extent, keep away from the theatres because they find that after stewing in some overcrowded and heated theatre on the previous night their brains are not sufficiently clear in the morning to allow of the faithful performance of their duties. We say it with all humility, but with the certainty that we are right, that theatrical managers are thus deprived of the most intelligent and most discriminating portions of their audiences, and that the lack of patronage of theatres by the professional classes must tell against the best interests of the drama, for every educated person must admit that there are dramatic interests which are higher than pounds, shillings, and pence. We doubt if any theatre has yet been built in London in which the question of ventilation has been considered of prime importance by the architect. Theatres have been built in New York and on the Continent (notably, we believe, at Frankfort) in which the ventilation has been efficiently provided for, and in which the visitors get fresh air of a regulated temperature without draughts.

Surely the ventilation of a theatre is no very difficult matter. The Board of Works now compels every theatre to have outlets on every side, and where there are outlets for visitors there must be room for inlets of fresh air. The vertical delivery of fresh air (if the tubes be large enough and in sufficient quantity) may be managed without causing draughts, and no building lends itself better to the escape of foul air than does a theatre, provided holes be made for its escape. The central sunlight of a theatre is a most efficient outlet for foul air, and there ought to be no difficulty in providing other outlets of a similar kind in the lobbies and above the stage, and at the back of the dress circle, boxes, and galleries. Outlets, of course, are not alone sufficient; there must be inlets; and if these be provided in the proper place and proper quantity, there ought to be no draught when a door is opened, which is now one of the greatest nuisances experienced in our theatres. In our variable climate it is necessary that the temperature of the in-coming air should be regulated, and in this there ought to be no difficulty with the aid of steam coils and ice. It is needless to say that every theatre ought to have an officer whose special charge it should be to regulate the ventilation and temperature of the house. This is very necessary, because of the constant variation in the numbers present in the house and the extreme uncertainty of the outside temperature in our climate.

There is no doubt that something has been done to improve the condition of our theatres by the introduction of the electric light. This does not foul the air as does a gas light, but it does not assist—at least to the same extent as a gas light may be made to assist—in carrying off the exhalations from the 1200 or 1500 persons who are crowded into a very confined space. We feel tolerably sure that if the sum (a very large one) which is spent upon the electric lighting of a theatre were spent upon its ventilation on a rational plan, and the supervision of it, the gain in comfort and health to the public would not fail to be appreciated and would result in a gain to the manager.

THE *Liverpool Mercury* for Dec. 31st, 1886, contains the report of the committee to be submitted to the governors and subscribers to the Hospital for Women, Liverpool, upon the practice of frequent spaying in this institution. The members of the committee appear to be laymen, and when they came face to face with this question they found themselves in a very uncomfortable position. The funds fell away, subscriptions did not come in, and what appeal could be made to the public on behalf of an institution in which a noticeable part of the work done was the removal of the uterine appendages? Under these circumstances the committee appears to have lost its head, and to have sought guidance chiefly from those who either claim to be inventors of the operation, or who are regarded as adepts in its performance. The replies of several of those who were consulted are given in the report; they all, with one exception, tend in one way—that is, to justify the frequency with which spaying was performed in the hospital. The exception was the reply of Sir SPENCER WELLS, which appeared in our columns last year. He stated that he regarded the statement that 111 (it should be 169) of 347 in-patients were subjected to abdominal section as so shocking as to be almost incredible. The committee endeavours to lessen the value of this letter by the statement that the number operated upon was really taken out of 3800 patients, and that all in-patients might have had to undergo abdominal section. Hospital patients, however, in Liverpool, differ but little from those in London and elsewhere; they suffer from the same diseases, and the proportion of those requiring abdominal section is much the same in every large town. Sir SPENCER WELLS is intimately acquainted with this class of patient in a hospital for women in London and his criticism must be considered to have much weight.

As soon as the question of the too frequent resort to the operation came before the committee, it at once gave every assistance and facility for inquiry to the committee appointed by the Medical Institution, and at the same time passed a resolution calling upon the medical officers of the hospital "to keep a record of

Digitized by Google

the operations performed, stating the circumstances of each case, the name of the medical officer asked in consultation, and the fact that the patient or her relatives have been informed of the nature of the operation performed." The committee accepted the report of the committee of the Medical Institution (which appeared in our columns on Dec. 11th), and, with a view to carry out its recommendations, resolved that "no operation of a dangerous character, or that involves abdominal section, shall be performed (except in extreme emergency), without previously summoning a consultation of the consulting and acting surgeons for in-patients."

These resolutions are good so far as they go, but they are insufficient. It is not enough to tell the relatives and friends what the operation is; the patient herself, being of adult age, should be told, and have the opportunity to consent or refuse to undergo the operation, after a full explanation of its nature has been given to her. Further, it is not enough to describe the operation in words the patient cannot understand, and the consequences of it as sterility. Women do not know what the removal of the uterine appendages, ovaries, and tubes means, or what it involves; when told it would prevent conception, many think it on that ground alone a highly desirable operation. They should be made to understand that the operation is really spaying, and thus be placed in a position to refuse or consent to it. Should this recommendation be carried out, we shall look with interest to the future records of spaying in the Hospital for Women, Liverpool.

Annotations.

"Ne quid nimis."

THE FELLOWS, MEMBERS, AND COUNCIL OF THE COLLEGE OF SURGEONS.

WE would once again draw attention to the petition now being circulated by the Association of Members of the College of Surgeons amongst the Members of the College throughout the country, and urge on them the desirability of at once sending in their signatures and their adhesion to the principle for which it contends—viz., the right of Members of a certain standing to vote in the election of Council, and to be themselves directly represented on the Council. The latest action of the present Council, in polling the Fellows on questions not actually raised by the Members, or raised by them in a different sense, looks so suspiciously like an attempt to influence their voting in a manner prejudicial to the interests of the Members, that nothing, we fear, now remains but for the latter to rely on that "self-help" which, after all, is the mainspring of every real success. It seems very improbable that the Council will make any such concessions as will satisfy the Members, or meet their just aspirations. Hence, the Members must take the matter seriously in hand and act on their own behalf. Under these circumstances, the sooner this petition is presented the better for its success; and it is important that it should be well and universally signed. We hear, with pleasure, that many of the larger towns, such as Manchester, Bradford, and Shrewsbury, have already responded with something very like unanimity. Nevertheless, many names are still required in order to get even a majority of the total number of Members at present enrolled, and this can only be done by a fairly general signature of surgeons at home, seeing that a large number of Members of the College are established in the colonies or are on foreign service. We would therefore impress diligence on all the local secretaries, as much for the purpose of securing signatures as of expedition and the saving of unnecessary expense. The statement of accounts for the past year shows a "balance deficiency" of £5, with outstanding liabilities for printing &c. of a further £20. Such a work as the present cannot be carried on without funds; and while we may congratulate the Association on the work they have already accomplished at so small an outlay, we must impress on all those who have not yet sent in their contributions, that as the advantages which will be gained by this movement are to apply to all the Members of the College, it is only fair and just to the promoters that Members should at least guarantee them against pecuniary loss in the proper carrying out of this work.

FEVER CASES IN GENERAL HOSPITALS.

AN animated meeting of the governors of the Sussex County Hospital was held on Dec. 29th, under the presidency of the Mayor of Brighton, on the question whether the hospital should be utilised in the future for the reception of cases of scarlet fever, typhus fever, and measles. A resolution for the exclusion of such cases was moved by Mr. Furner, seconded by Mr. Boxall, and supported by several governors. It was, however, somewhat strenuously opposed by other speakers, mainly on the ground that the hospital was a county one, and should be open to all classes of disease. It was pointed out that since the hospital was founded sanatoria had been established in Brighton and Hove, where such cases can be treated; and seeing that the hospital cannot afford special accommodation for fever cases, or furnish a special staff, the meeting did well to adopt the resolution, which it did by 66 votes against 22. It is needless to dwell upon the undesirability of admitting contagious fevers into a general hospital where provisions for complete isolation do not exist; and in arriving at this decision, the governors of the Sussex County Hospital have only followed, although somewhat tardily, an example which has been set them years ago by the majority of such institutions. It is, of course, another question whether a fever block could not be added to the existing buildings, so as to remove the reproach that a county hospital could not provide accommodation for all classes of disease; but this is a matter involving a considerable outlay. Moreover, in the case of Brighton there seems to be sufficient accommodation for fever patients at other institutions in the town: and if this be not the case the Corporation should not delay to make the necessary provision.

MELANOTIC SARCOMA.

THE study of pigmented new formations can hardly as yet be said to have resulted in a thoroughly clear and satisfactory explanation of the reason for their pigmentation or its source. It is admitted that such growths are almost invariably sarcomas, and that their primary seat is in connexion mostly with tissues that normally contain pigmented cells—e.g., the retina and choroid, and the rete mucosum of the skin,—although it may be remarked, in passing, that these are not invariably mesoblastic tissues. But even the source of the pigment is questioned. All body pigment comes, we suppose, from the blood; but in melanotic sarcoma this may be either direct (i.e., actual hæmatin) or indirect (i.e., melanin), due to the special operation of the cells composing the neoplasm. The subject has lately received fresh investigation at the hands of Dr. Oppenheimer of Berne (Virchow's *Archiv*, Bd. 106, Hft. 3), who proves that cases of melanotic sarcoma may be ranged in two groups. In the one, the pigmentation is

Digitized by Google

clearly referable to local conditions of blood-supply, in the distribution of the bloodvessels and the diapedesis of red corpuscles. In the other, the formation of pigment takes place from the first within the cell protoplasm; and in one such case a chemical analysis proved an absence of iron, but the presence of a considerable quantity of sulphur, thereby excluding a direct relation of the pigment to hæmatin. Chemical analyses, however, seem to be rather defective upon the composition of melanin, and it would be well if they were repeated, with a view to determine whether the relative proportions of iron and sulphur do vary as suggested, and also with a view to the comparison of melanin and hæmatin. Upon the result of such inquiry may depend, according to Oppenheimer, whether we may have to break up the unity of melanotic sarcomas. He has no fear himself that this unity will be disturbed, considering that an explanation of varieties in chemical composition of the pigment may be found in the operation of the cell protoplasm—in the one case leading to new combinations with hæmoglobin, whereas in the other the blood pigment is left more or less unaltered, as hæmatin. In any case iron ought to be present, if not in the pigmented, at least in the non-pigmented portions of the growth, if the doctrine that the red corpuscles are the primary source of the pigment is to be retained. This, therefore, is eminently a question for pathological chemistry. Histology has done its work, but there are limits to the information it can yield, and it seems as if in the end many vexed questions will have to be solved by other methods than microscopical examination.

PROMOTION IN THE ARMY MEDICAL STAFF.

OUR attention has been called by a correspondent to the existence of a regulation, bearing date Nov. 1st, 1884, that "medical officers of any grade promoted for distinguished service will be exempt from further examination." We regret that we had overlooked this, owing to its not being included in Vol. I. of Army Regulations, published by the War Office in 1884. The promotion of Surgeon-Major Mackinnon, therefore, without undergoing an examination, would not have been against the regulations, but it would have involved an act of great injustice to the large number of officers over whose heads he would have passed. We have always advocated the system of substantial rewards to medical officers for valuable professional work, but such rewards ought not to inflict unmerited punishment upon their less fortunate brother officers. We rejoice at Surgeon-Major Mackinnon's having been granted the distinction of Companion of the "Distinguished Service Order," while we feel that his promotion to brigade surgeon over the heads of above ninety officers of his own service would have been an act of great injustice to them.

THE COTTON COMPRESS IN ORCHITIS.

IN a recent number of the *Revista Argentina de Ciencias Médicas* Señor José M. Escalier gives an account of a very successful method of treating orchitis and epididymitis by means of a cotton compress, which has been for some time in use in Dr. Montes de Oca's wards in the Hospital de Clinicas in Buenos Ayres. The idea was taken from the cotton cap or suspensory bandage of Langlebert. The apparatus is applied as follows: The neck of the scrotum is first secured by a bandage and strapping, the testicles being thus driven downwards. The scrotum is then enveloped in a silk handkerchief, outside which a thick layer of cotton-wool is applied, and the whole covered with a gutta-percha cap. Strips of plaster are now passed round in a circular manner, so that the ends can be drawn more or less tightly before being fixed, in order to exert a compressing force on the glands. In the first stage of orchitis, when there is not much epididymitis, the compress arrests the inflammation and brings about resolution rapidly. The cases in which this occurred, however, were but few, as nearly all the patients who presented themselves at the hospital had passed that stage. In some cases of acute orchitis very moderate compression was resorted to with success, but of course the pain was very great and the patients did not bear it well. In these cases the best treatment was found to consist in making a number of punctures to give exit to the liquid in the tunica vaginalis together with some blood, then to surround the scrotum with ice, and to give a purgative. After this treatment has reduced the inflammation the cotton compress can be applied with advantage. With practice the degree of tension required in each case can be adjusted to a nicety, and in twenty-four hours the swelling will generally have diminished so much that it is necessary to reapply the compress. After two or three of these reapplications the testes return to their normal size, and a slight induration of the epididymis is all that remains. The cure is usually complete in a week, or even less. The cotton compress has been used in more than a hundred cases, and is, according to the writer, far more satisfactory than any of the ordinary methods of treatment. Even in chronic cases it is astonishing to see the rapid effect that it produces. It has also been successfully employed after tapping hydroceles.

COUNTRY PRACTICE AND PRACTITIONERS.

THE duties which belong to the province of the busy practitioner of medicine are under any circumstances sufficiently arduous. The frequent difficulty of the work itself, its accidental and untimely character, and the necessity for study during snatched intervals of leisure, combine to form a whole which must fairly tax the resources of human energy. These observations apply with particular force to the lot of the general practitioner in a country district. The circumstance of position, while it increases his responsibility, usually diminishes in the same proportion his facilities for meeting it. Roads, weather, and distance are obstinate realities to him, and are apt at critical times to magnify surprisingly the meaning of emergencies. Distinctions between one department of practice and another are necessarily but nominal in his experience. In him the surgeon and physician are combined, and we are reminded that the art of healing is one whole. It is this fact mainly which gives to his life its peculiar character, and it is this, too, which constitutes its chief honour. The brilliant results of success in a limited field are not his; the emoluments of a wealthy and distinguished *clientèle* may not reach him; but it belongs to him that he may and does satisfy as fully as his most favoured brethren the needs of suffering mankind, whether incurred by injury or sickness. The man who is sufficient for such duties must be no weakling of his kind. Strong—that is robust—in frame, perhaps, he need not be, often he is not; but endurance he must have. Whatever his person, there must be in him the capacity for work, for standing wear and tear. His mind, too, must be of the right temper. It is not enough that some one or two faculties should rule his character and conduct. Courage, energy, coolness, reserve, firmness, cheerfulness, must meet in him to ensure no more than practical efficiency in the ordinary round of a well-filled day. Nor is the moral nature untried. There will be many occasions on which each man's perception of justice and humanity will become evident in the presence of doubt or provocation—times even when manhood will seem wanting without some faith in a higher wisdom. We have seen it stated that the old type of practice such as we have sketched is disappearing, and with it the old practitioners. We should much regret if it were so, and we think otherwise. Developments in

Digitized by Google

theory and practice there have been, and facilities are more numerous than of yore, but there is, and will long remain, ample scope for the exercise of well-directed energy and friendly feeling, and we maintain that the mantle of a manly and unselfish ancestry has descended on a generation worthy to succeed it.

BISULPHIDE OF CARBON POISONING.

IN the narration of two cases of chronic poisoning by carbon bisulphide, contributed to the current issue of the *Medical Chronicle*, Dr. Ross directs public attention to the risks run by workers in indiarubber factories, where that substance is largely employed. As clinical records, also, the cases are of considerable interest. The first was that of a man, twenty-four years of age, temperate, and of previously good health, who for about eight months had been engaged in an indiarubber factory. He was employed in the "curing-room," and subjected to the fumes of the bisulphide. After a few weeks he suffered from a burning sensation in the hands and face, which were hot to the touch and of a red colour. When the hands were put into cold water they immediately became livid and cold and numb. He became restless and fidgety, and a few weeks later experienced tingling sensations and numbness in the feet and hands, with progressive weakness of the limbs. He now rested for two or three weeks, during which he recovered; but a few weeks after resuming work the old symptoms returned. He now had great difficulty in walking, and could scarcely hold anything in his hands, attempts at grasping being accompanied by much tremor. He could not get rid of the odour of the gas; his food seemed to taste of it, so that he had a loathing for food. He lost flesh, the wasting of the arms and legs being disproportionate to that of the rest of the body. His memory failed him, and he passed restless, disturbed nights. At last he became too feeble to walk, and left the factory four weeks before his admission last May into the Royal Infirmary, Manchester, where he remained a month. He there improved considerably, but was still unable to produce dorsal flexion of the feet, and the knee-jerks remained absent. After a sojourn at the Cheadle Convalescent Home he returned, showing hardly a trace of the previous paralysis. The second case, which was under observation at the same time, was also of a young man twenty-four years of age, with a good health record. He had been working for nine months in the "curing-room," but it was three months before he began to suffer any ill effects. Then he complained of the odour of the gas, and of his food tasting of it. He became unable to read, and deaf in the left ear. His legs felt heavy and weak, and he had tingling sensation and numbness in the hands and feet, the effect of cold water upon them being similar to that noticed in the first case. His sleep also was disturbed by dreams, and he became depressed and miserable, but found, as did the other patient, that inhalation of the fumes brought temporary relief to his sufferings. His memory became defective and he had delusions. It appears that other workmen employed in the factory have been similarly affected, and once or two have become insane. Dr. Ross points out that the paralysis resembles alcoholic paralysis more than any other form of progressive multiple neuritis; but the muscular hypersthesia noted in alcoholic paralysis was entirely absent in these cases. The amblyopia and loss of colour vision noted in the second case do not occur in alcoholic paralysis unless complicated with tobacco amblyopia. Sometimes inhalation of the fumes of bisulphide of carbon gives rise to symptoms resembling those of acute alcoholic poisoning, as in case mentioned by the second patient closely resembling delirium tremens. "There can be no doubt," adds Dr. Ross, that these men suffered from a severe paralysis, of which the cause was that is caused by several toxic agents after a considerable experience of the paralysis caused by both alcohol and lead—which are the usual sources of such poisoning in this country—I have no hesitation in saying that the disease from which these men suffered was not caused by either of those agents. If it be true, then, that we have in our midst certain workshops in which the process of manufacture is so deleterious to the health of the workman that a certain proportion of them is reduced in a few months to the pitiable condition of paralytic helplessness manifested by these two unfortunate men, it is hardly necessary for me to maintain, in the face of all recent factory legislation, that these workshops ought to be placed under the most stringent regulations, and be subject to the frequent visits of a Government inspector."

SIR JAMES PAGET ON SCIENCE v. CLASSICS.

THE just issued number of the *Educational Times* (edited by Mr. W. J. C. Miller, B.A., registrar of the General Medical Council) contains a speech by Sir James Paget on the occasion of delivering the prizes and certificates to the London Centre for the Oxford Local Examination in the theatre of the London University, which deserves attention. It is remarkable for the strong assertion of the claims of science in education. He speaks in a tone of warning as well as complaint. Under our present system, with only classical scholars at the head of schools, men of science have no chance. And he is not prepared to admit that the study of classics or literature is a more efficient instrument for training the minds and powers than the study of natural science. Yet men of science are wanted everywhere, and when it is asked where they come from, the answer is, "they all come from Germany." Let the schools, says Sir James, take warning in time. Nor will he agree in common education to postpone science to a late age when work has to begin and the problem of living has to be faced. Sir James was questioned by Sir Thomas Fowell Buxton on the subject of school-pressure on girls, and of the effect of higher education on women. Sir James Paget did not believe that there was need for so much fear as is felt on this question, and in the cases of the successful candidates of London he never saw any signs of physical exhaustion or any evidences of overwork, nor had he seen a single case to lead him to believe that the higher studies were detrimental to the charm or beauty of women.

THE REMOVAL OF SNOW.

THE recent heavy fall of snow, which has not yet entirely passed away in thaw, and may not soon altogether disappear in this way, has not failed to bring out suggestions as to the means best suited for its artificial removal. Spade, sand, and salt have each been freely and effectually used, and the last of these, as employed in this country, has been made by more than one observer a subject of censorious comment. The censure, indeed, is not undeserved, for there are distinct disadvantages connected with this use of salt. It has been urged, with good reason, that its effect in producing a freezing mixture must not be forgotten when we thus avail ourselves of its primary action as a snow solvent. The absorption of heat from the surrounding atmosphere, and the living bodies which inhabit it, must be considerable even in a natural thaw, but it is clearly much greater when the same effort of nature is imitated in an atmosphere already cold by means of an agent which secures its rapid and thorough accomplishment. This is what happens when salt is used for clearing snow from pavements, tramway lines, and the like, and the fear of consequent chill to man and beast while travelling thereby is not imaginary. Another objection might be urged against this use of salt. The freezing action to which we have referred must act upon surrounding snow and water, so

Digitized by Google

that outside the area of artificial thaw there is formed a zone of artificial ice. This may not much signify in every case. In the case of pavements and footpaths it must be guarded against. For clearing all such, and assuring a firm foothold, there is nothing better, in our opinion, than the combined use of spade and sand. For frozen roadways ash or sandy gravel is, on a similar principle, deservedly esteemed, and though salt appears to be still the best means of treatment for tramway lines, it is only necessary that here, as in France, when once its work is done, the resulting chill should be obviated by sweeping the road.

ABSORPTION OF FAT IN ACUTE INTESTINAL CATARRH.

DR. VIAZHLINSKI, who has been working in Professor Ivanovski's laboratory of pathological anatomy in St. Petersburg, has published an interesting paper on the question of the absorption of fat in acute catarrh of the small intestine. The literature which he first alludes to comprises more than ninety papers &c., including those published by Goodsir Schäfer, and Watney in this country. His own observations were conducted by inducing acute intestinal catarrh in animals by means of irritant drugs, and then feeding them with milk or other fat-containing food, after which the animal was killed and the intestinal villi examined with the help of osmic acid, which he found the most satisfactory agent for making the preparations. The drugs used were colchicin and croton oil. Several animals (cats and dogs) died, so the quantity of colchicin was reduced from one-thirtieth to one-sixtieth or one-hundredth of a grain, which produced choleraic stools. Croton oil was given in repeated doses of five or six drops, producing diarrhœa with exhaustion. When the animals presented, besides diarrhœa, an inflated abdomen, constant borborygmi, and a considerable degree of exhaustion, an acute catarrh of the small intestine was considered to have been established, and the fatty food was administered. The microscopic observations showed that in catarrhal conditions, as well as in health, the fatty particles are absorbed by their inclusion within round or amœboid cells — i.e., leucocytes, — the difference in the diseased state being merely a quantitative one. No evidence could be obtained of any part being taken by the epithelial cells in the absorption of fat.

INQUESTS WITHOUT NECROPSIES.

A SHORT time since Mr. William Carter, coroner for East Surrey, held an inquest on the body of a man named Turner, aged thirty-nine years. Deceased "had always enjoyed remarkably good health," and on the day of his death left home for work apparently quite well. He was found in the street with his face downwards, and when Dr. Sterling saw him he was quite dead. There was absolutely nothing to show the cause of his decease. It might have been from rupture of an aneurysm, apoplexy, epilepsy, or other natural disease, but beyond the fact that there were no signs of violence, it might equally well have been from injury, poison, or what not. Dr. Sterling very properly refused to certify without a post-mortem examination. The coroner left it to the jury to decide whether this was necessary, and the latter returned a verdict of "Death from natural causes." If ever there was a case that called for further inquiry it was this. A man in the prime of life, who up to the time of his death was not known to be suffering from any ailment, dies suddenly and from some unknown cause, and yet his case is not deemed worthy of that particular investigation which alone could have furnished evidence to justify the verdict returned. The inquiry, if correctly reported, seems to us to have been a mere farce.

HEALTH OF CALCUTTA.

THE report on the health of the town of Calcutta for the third quarter of 1886, by the health officer Dr. Simpson shows a satisfactory reduction of the death-rate compared with the average of the preceding ten years, in only three of which it was lower. But the deaths from cholera were more numerous than in any of these years; they amounted to 230, of which 95 occurred in July, 55 in August, and 80 in September. We regret to add that this high rate of deaths from cholera has continued in Calcutta, for the weekly returns show them to have risen in October to 265, and in the four weeks of November to 326. The great increase in July was supposed to be due to "an influx of infected pilgrims. ..... The cholera of August and September must be attributed to Calcutta only." Although much has been done of late to improve the sanitary condition of the town and suburbs, there appears still to be great room for active operations in this direction. Dr. Simpson points out, as a condition unfavourable to health and favourable to cholera in the bustees, the impure water-supply. "The recourse had to polluted well and tank water is, without doubt, a very fruitful cause of disease." Their drainage also is very unsatisfactory. The huts and their surroundings are kept in a most filthy condition; they are greatly over-crowded, and it is impossible for fresh air to gain access to them. "Two of the most important factors in the health of a locality—efficient ventilation and scavenging—are wanting; and two of the most potent factors favourable to cholera are present—viz., stagnant air and filth." The measures already taken seem to have produced satisfactory results in reducing the death-rate of the town, and it is to be hoped that the extension of the supply of pure water, the adoption of an efficient system of drainage, and the introduction of building regulations into the Municipal Act may be productive of similar beneficial effects in the suburbs. During the quarter under review the deaths were in the annual ratio of 23·1 per 1000 of the population in the town of Calcutta, and 33·5 in the suburbs.

QUARANTINE AND SMALL-POX.

ON the arrival of the Norddeutscher Lloyd steamer *Preussen* at Adelaide from Southampton the occurrence of a case of small-pox was reported, the result being that the vessel was placed in quarantine. According to a telegram, however, it would appear that, in addition to twenty-four cases which subsequently occurred, thirty persons who landed at Sydney are sickening, besides several at Melbourne.

THE PREVALENCE OF SCARLET FEVER AND MEASLES.

IT would be premature to assert that the extensive local prevalences of scarlet fever and measles which are now being reported from time to time indicate a general extension of these diseases. But it is certainly noteworthy that in special localities very large outbreaks have been taking place during the past few months. At Merthyr Tydfil 95 fresh attacks from scarlet fever were reported at the December meeting of the local board, and efforts are being made to check it by an extension of the Christmas holidays and by the cleansing and disinfection of schools. At Aberdeen 107 cases were reported in September, 78 in October, and 107 in November. At Kirkcaldy both scarlet fever and measles are exceptionally prevalent. And, again, an alarming and sudden outbreak of scarlet fever is reported to have occurred at Wimbledon and Merton, some 400 cases having shown themselves since Christmas. In this latter case whole families are stated to have been attacked, and it is suggested that the epidemic has had its origin in an infected dairy. As regards measles, it was a heavy factor in the Leeds death-rate for the

Digitized by Google

month of December, the inclement weather tending to increase its fatality. At Hexham the occurrence of 150 cases has led to the closure of both day and Sunday schools, but the type is said to be mild and non-fatal. The last quarterly return of the Registrar-General had to do with the third quarter of 1886, and it then appeared that, although the scarlet fever death-rate was exceptionally heavy in certain places, the annual rate was only one-half of that which constituted the average for the ten preceding third quarters. Measles was also very fatal in a few places, such as in Illogan, Camborne, Newcastle-under-Lyme, and Tamworth subdistricts, but the annual rate was precisely the same as that which constituted the mean for the previous ten similar quarters. When the next return is issued it will be seen how far these severe local outbreaks are associated with any general prevalence of the diseases in question, but in the meantime sanitary authorities would do well to arrange, as far as possible, for early isolation in the case of first attacks.

THE BRISTOL MEDICAL SCHOOL.

THE Principal of University College, Bristol, has recently made an urgent appeal to the wealthy inhabitants of Bristol and its neighbourhood for £5600 or £6000, in order to provide proper buildings and equipment for the Bristol Medical School, which has existed since the year 1828, and has furnished a large proportion of practitioners of the highest standing to Bristol, Clifton, and the adjacent districts. The Bristol School in times past has been a most flourishing one, and, even with the great competition which now exists, still numbers nearly a hundred students, and performs a most useful and honourable function for the west of England and South Wales. Following the example of other provincial schools, it has associated itself with the University College of Bristol for the instruction of its students in the less strictly medical branches of scientific education, and the appeal of Principal Ramsay comes therefore with much grace and weight. A medical school without adequate laboratories, class-rooms, and dissecting-room is as inefficient for the teaching of the necessary scientific subjects of a student's curriculum as is a hospital for clinical instruction, unless it possesses a fair proportion of beds to the number of its students. The tendency of the present day is evidently to congregate all schools of medicine around a University as a centre, and to secure the efficiency of the appliances and teaching of such schools under some form of University supervision; and it is therefore especially important to the Bristol teachers that they should be able to insist in every respect on their claim to a proper consideration and recognition in this University question. Feelings of gratitude for many services rendered to the citizens by medical men educated at this old provincial school should lead to such a comparatively small sum being readily subscribed by the merchants of the ancient city.

STAWELL HOSPITAL.

THE report of this institution—which is situated at Stawell, Victoria, and was formerly known as the Pleasant Creek Hospital—for the year ending July, 1886, has recently been issued; and, considering the general depression existing in mining, agricultural, and pastoral industries throughout the district, is a highly satisfactory one. The number of in-patients for the year was 281 as against 224 for the preceding twelve months, and of out-patients 283 as against 231. The year commenced with a debit balance of £224, but, we are glad to note, ended with a credit balance of £89. The fact that the private subscriptions to the hospital have considerably increased affords strong testimony to the energy and [illegible] of the secretary, Mr. C. B. Playford.

THE PROVISION OF SPECIAL HOSPITALS BY SANITARY AUTHORITIES.

THE Local Board of Health of Winsford having given a subscription of five guineas to the Manchester Eye Hospital, the members of the Board were surcharged that amount by the Government auditor on the ground that the institution in question was not one for the reception of infectious diseases, for which sanitary authorities are legally entitled to make provision. The auditor's decision has, however, been reversed by the Local Government Board, and the fact is worth noting. It is quite true that Section 131 of the Public Health Act, 1875, which gives power to local authorities to provide hospitals, is one of a group of sections included under the heading "Provisions against Infection," but it has long ago been decided that the interpretation of an Act of Parliament is to be governed by the wording of its sections, and not by headings which are merely inserted for the purposes of convenience. Now Section 131 in no way limits the class of hospital which may be provided or supported by a local authority, and hence there is no reason, in so far as the Public Health Act itself is concerned, why sanitary authorities should not provide other than infectious hospitals. Indeed, we believe there is an instance in which the Local Government Board were willing to aid an authority, by way of loan, to provide an accident hospital, and we can quite conceive that there may be districts where special trades are carried on, in which it would be a distinct gain to public health that special hospitals for other than infectious diseases should be provided at the public cost. The alternative often is the use of a workhouse infirmary for those who sicken in the performance of work on the success and amount of which the prosperity of a district and of its population depends.

"NERVI NERVORUM PERIPHERICORUM."

DR. J. PRUS of Cracow has described in the *Przeglad lekarski* a nervous network existing in the perineurium of nerve-trunks, which he calls "nervi nervorum peripheri-corum," and which, he says, must not be confounded with other nervi nervorum which have been previously described, those mentioned by Bourgery and by Hirschfeld referring to nerve centres only, and those misnamed nervi nervorum by Krause being merely nervi vasorum. Dr. Prus's observations were conducted by injecting methyl blue, according to Ehrlich's method, into the bloodvessels of living animals. By this means the nerve tissue became coloured, so that the beautiful nervous network in the perineurium became visible on microscopic examination. The endoneurium is also provided with this network, but to a much smaller extent than the perineurium.

DECOMPOSITION IN TINNED MILK.

IT would be superfluous in these days to enlarge on the utility of condensed milk and the necessity that it should be prepared and preserved in the best manner, and sold only of the best quality. Less liable to fermentative change than fresh cow's milk, and preferable, as being lighter, to the majority of prepared foods, it is practically one of the essentials of infant life. Diarrhœa is well known to be one of the commonest and most fatal illnesses of childhood. Among its known causes, probably none is so usually effective as the souring of milk, the staple diet at this age. Such an accident is unfortunately only too common when a feeding-bottle is managed by a careless nurse. Its worst consequences are assured when tinned milk actually becoming putrid from fermentation is bought and used by the poor, and that this has happened we have proof in at least one case. At the Edmonton sessions last week a grocer was convicted of selling, at a nominal cost, condensed milk in

Digitized by Google

tins, the very appearance of which indicated the process of decay within them. On opening some of these a spurt of gas and milk escaped, and the taste and smell of the contents were very disagreeable. The poisonous trash was being rapidly sold, especially for the use of children. There was evidence enough to show that the vendor was aware of the condition of the milk, and there can be no doubt of the justice of the penalty imposed upon him. In the circumstances we may be excused for alluding to the obvious caution conveyed by this incident, that purchasers, particularly of this kind of food, should buy wisely rather than too cheaply.

ABOUT CHILDREN.

LORD YOUNG, when recently occupying the chair at a lecture delivered by Dr. Russell, the medical officer of health in Glasgow, before the Edinburgh Health Society, expressed an opinion that the views of Malthus had better be impressed on those who are responsible for the existence of children. Without doubt this is a practical view of the matter, and it is one that goes to the very root of the difficulty as to the management of children—"Don't have so many of them." As it is, we must take things as we find them, and hence the necessity for bestowing more than ordinary care on the preservation of child-life, especially in cities. We are glad to know that attention is being pointedly directed to these matters by coroners and medical officers whenever opportunity offers. Some remarks made not long ago, at an inquest held by Mr. Price, the coroner for Oldham district, are particularly worthy of note. He insisted strongly on the need of prosecuting inquiries rigorously into the causes of death in cases of infants found dead in bed with their parents, life having ceased in the early morning. Mr. Price was of opinion that these children were suffocated, and he very properly urged the expediency of having medical evidence in all cases of this class. The Society for the Prevention of Cruelty to Children have just issued a little paper entitled the *Child's Guardian*, which will be devoted to the best interests of the little ones. We heartily wish the venture success, and feel sure it has a wide sphere of usefulness before it.

THE INFLUENCE OF COCAINE ON THE ACTION OF ESERINE ON THE EYE.

IT was remarked by Wecker in the *Annales d'Oculistique* (1884, t. xcii., p. 218) that the action of eserine on a cocainised eye is greater than when no cocaine had been used. This difference he attempted to explain by suggesting that the slight cocaine-anæsthesia of the iris and ciliary body may cause a somewhat similar effect on the pupil to that of eserine. Dr. E. L. Turevich, however, who has recently published a "preliminary communication" on this subject in the *Vrach*, points out that the action of cocaine by itself on the pupil and accommodation is exactly the reverse of that due to eserine, cocaine dilating the pupil and paralysing the accommodation, while eserine contracts the pupil and causes spasm of the accommodation; besides, it has been conclusively shown that a combination of atropine and cocaine produces a more powerful dilating effect on the pupil than atropine alone; and Ad. Weber has even given the equivalents of eserine and pilocarpine as antagonists of cocaine, these being 1 : 25—30 in the case of eserine and 1 : 4 in the case of pilocarpine. The fact of eserine acting more powerfully on a cocainised eye is therefore paradoxical, and by no means easy to explain. How, writes Dr. Turevich, can the anæsthesia of the ciliary body, even if cocaine does produce such an effect, which is extremely doubtful, favour the action of eserine, as Wecker suggested? We should *a priori* expect that the contraction of the pupil by eserine in a cocainised eye would be, if anything, less than in an ordinary eye; and indeed it was shown by Weber that when a drop of a 2 per cent. solution of eserine was combined with twenty-five to thirty drops of a similar solution of cocaine, its effect on the pupil was entirely masked. In the hope of clearing up the paradox Dr. Turevich undertook a series of observations on the paralysing effects of eserine and pilocarpine on his own eyes and on those of others, both with and without the previous instillation of cocaine. The course of the accommodation-spasm was observed by measuring the refractive power of the eye every five minutes from the application of the eserine or pilocarpine to the time when the effects had passed off. Fifteen comparative observations were made, which completely confirmed Wecker's statement as to the greater effect of eserine on a cocainised eye, showing also that the same is true of pilocarpine. The explanation suggested of the apparently opposite action of cocaine when applied previously to the eserine and when combined with it is that when anæsthesia of the conjunctival sac is present—first, the surface absorbs more of the eserine than when the eye is as sensitive as usual, the introduction of a foreign liquid causing less winking with less consequent expression of the liquid between the lids; secondly, the secretion of mucus is smaller, and thus the solution is less diluted and less likely to be washed away; and thirdly, the conjunctiva and cornea are drier, and thus absorb the eserine more readily. The author convinced himself by special experiments of the difference in the behaviour of cocaine according as it was applied before or simultaneously with the eserine or pilocarpine, and the above explanation is the only one which appears to him adequate to explain the apparent paradox.

SPEECH DAY AT THE ST. PETERSBURG MEDICAL ACADEMY.

THE annual speech day of the St. Petersburg Military Medical Academy was held on Dec. 7th, when Professor Botkin gave an address on the General Bases of Clinical Medicine. The statistical report, which was read by the Secretary, Professor Pashutin, contained the following information: The present staff consists of 33 professors, 30 privat-docents, and 7 prosectors. During the year 7 privat-docents had obtained professorships, either in the Academy or in Russian universities. The number of students amounted to 935. 87 diplomas as *Vrach* were given, also 57 M.D. degrees. (The higher grade is only conferred on those who have already taken the lower.) No less than 454 of the students had scholarships from public or private sources. The Academy has during the year lost two of its staff by death—Professors Butleroff and Kolomnin. The proceedings terminated by the usual distribution of medals and prizes to the students.

LOCAL ASPHYXIA OF VISCERA.

THE coexistence in the same individual of Raynaud's disease and paroxysmal hæmoglobinuria is a well-attested and thoroughly authenticated occurrence. It is tempting to translate the renal change in the light of the nature of the local asphyxia of the peripheral parts of the body. The dependence of the skin and kidney conditions on the influence of cold, as perhaps the most important etiological factor, seems to stand in favour of this view. Dr. John Abercrombie, in a lecture on this subject delivered at the Hospital for Sick Children, and afterwards published in the *Archives of Pædiatrics*, writes as follows:—"Are we warranted in saying that paroxysmal hæmoglobinuria and Raynaud's disease are the same thing? I believe we are—i.e., I believe hæmoglobinuria is a symptom of the more general affection, and, being the one that most attracts the

Digitized by Google

patient's attention, the other phenomena escape observation." Dr. Abercrombie also draws attention to the occurrence of slight jaundice in some cases of paroxysmal hæmoglobinuria, and the inference that this may be a kind of Raynaud's affection of the liver is suggested. Attacks of amblyopia also occur. Ague has undoubted relations to hæmoglobinuria and Raynaud's disease. Disposed as we are to agree in the main with Dr. Abercrombie, yet in the hæmoglobinuria there need not necessarily be a general affection of the whole system. The incidence of the disease may be varying, both in time and site—now this organ, now that, being the seat of local asphyxia; and occasionally there may be the wider distribution of the paroxysmal changes, as, indeed, is witnessed in the skin in different cases. To explain the special frequency with which the kidney appears to be affected, the remarkable physiological connexion, that is illustrated in many ways, between the renal and the cutaneous arteries and tissues should be remembered. An interesting contribution to the study of Raynaud's disease may be read in our report of the Pathological Society.

THE PATHOLOGICAL SOCIETY.

THE Council has decided to make some efforts to deal with the *embarras de richesse* which overwhelms the proceedings of this Society and yearly grows greater. Some kind of scrutiny is to be exercised, but the precise machinery and methods have not yet been constructed. We have for many years past urged the necessity for some action of this kind. In adoption of the principle of card specimens without publication of descriptions in the Society's Transactions may perhaps meet a part of the difficulty. This year the Society loses the services of Dr. Bristowe and Mr. Butlin. It can be no exaggeration to say that the Society was never better served by a president and a surgical secretary than by the two gentlemen named. Dr. T. Barlow certainly gave expression to a widespread feeling when proposing the vote of thanks to Dr. Bristowe. It must be regarded as one of the best traits of the past president's estimable character, that he keeps in touch with the young and hard-working members of the profession, and shows in this sympathy an earnest and successful endeavour to cope with the pathological aspirations of the times.

GOITRE AND CRETINISM IN PERU.

An interesting paper on Goitre and Cretinism in Peru was recently read to the "Union Fernandina," a Lima medical society, by Señor Antonio Loreña, who seems well acquainted with the European literature of the subject and the various theories which have been proposed to account for the endemic origin of these affections. He himself believes that no one of the suggested causes is alone sufficient to induce them, but that a most important factor in their etiology is a purely vegetable diet. He gives a detailed description of the valley of the Vilcamayo, in part of which goitre and cretinism are abundant, while in other parts they are absent, or nearly so, the general conditions remaining the same with the exception of greater civilisation and admixture of animal diet in the localities where goitre is absent. In some places, where forty years ago goitre was common enough, it has now nearly disappeared, the more intelligent inhabitants themselves attributing the change to the improved diet of the people. The author thinks the best prophylactic measures consist in opening up the districts where goitre and cretinism are rife by means of roads and stimulating the commerce of the district, which will lead to the people obtaining a more varied and palatable diet than the maize, which is now their sole article of food. Humboldt was, according to Señor Loreña, misinformed when he was told that goitre was unknown in South America before the eighteenth century, for there are preserved in many private museums wax figures with immense goitres dating from the times of the Incas, and there is now no doubt that goitre and cretinism existed during the empires of the Incas and Siris just as they do at the present time.

THE SANITARY STATE OF FOLKESTONE.

MR. CLEMENT E. PRIESTLEY, late medical officer of health for Halstead, is found fault with in the Folkestone local press for having contributed an article to THE LANCET on the subject of an outbreak of typhoid fever in his practice. He fully justifies his action in the matter, and he then goes on to state that both typhoid fever and a mild form of diphtheria are present in Folkestone, and that it is far better to acknowledge it openly and to apply the needed remedies than to make a secret about it. Folkestone suffered somewhat severely a few years ago. Between October, 1881, and June, 1882, as many as sixty fatal attacks of diphtheria took place there, and the non-fatal attacks were also very numerous. The proper ventilation of the sewers was then a matter which the sanitary authority were urged to carry out, and the reconstruction of house-drains was also found to be necessary. How far these still need attention we cannot say, but it is implied that a house-to-house inspection, proper control of slaughter-houses, dairies, and milkshops, and the prevention of overcrowding are required.

THE FOOD OF MAN.

THERE is no doubt that man can exist on a vegetable diet. He can obtain from the plant world, digest, and assimilate those materials which are needful for the repair of his own tissues. The arts concerned in the preparation of food will also undoubtedly aid him in his conversion of vegetable into animal equivalents, and will supplement his powers by shortening considerably the period required for gastric digestion. Still, after all has been said, it must be allowed that the labour of the alimentary tract is better adjusted and the formation of sound tissue more assured by the use of a mixed diet. If on the one hand we assert the proved value of hydrocarbons in organic combustion not merely as heat producers but as sources of energy, in support of our use of vegetables, we must also maintain that meat which yields us most easily the formative and stimulant proteids can hardly be discarded. Our internal physical conformation, which is intermediate between that of the carnivora and herbivora should afford at least a suggestive clue in our choice of a diet.

SPINAL DISEASE AND INSANITY.

DISEASE of the spinal cord has been frequently discovered in cases of general paralysis. Commonly enough, locomotor ataxy precedes the mental disease. The spinal disease is not, however, always of the ataxic type; other strands than the posterior are affected in general paralysis. Although familiar to some, the knowledge is not general that chronic insanity seldom spares the spinal cord. This fact is excellently illustrated by a thesis for the degree of M.D. Glas. by R. S. Stewart, M.B. Records are given of six cases of general paralysis, six of dementia, and four of melancholia, with four of imbecility, in all of which the spinal cord was examined after death. Changes were found in the brain and cord in all cases. Of the changes in vascularity little that is definite can be said, but we are disposed to pay more attention to conspicuous changes in the nerve cells of the cord. Dr. Stewart has discovered alterations in the large multipolar motor cells of the anterior horns in most of the

Digitized by Google

cases. He is inclined to think that degenerative atrophy of cells is a constant feature of almost all cases of insanity which have lasted some time. The atrophy is not purely pigmentary, but fatty also; the cell is smaller, with rounded angles, wasting of processes, and breaking down of edges. The subject is certainly of much scientific interest. We are impressed with the carefulness of the author, so far as can be judged by a perusal of the thesis. Dr. Stewart is to be congratulated on the direction which his studies have taken, for it is, comparatively speaking, *terra incognita*, and diligent labour is sure to be rewarded with rich results.

THE GOVERNMENT EMIGRATION OFFICE.

EMIGRATION may or may not be a panacea for the evils attending the existence of a surplus population in large cities, and especially in London; but that the institution of an Emigrants' Information Office like that established by the Government in Broadway, Westminster, is a wise step in the interests of intending emigrants, as well as one contributing, indirectly, to the comfort and well-being of those who remain at home, there cannot be a reasonable doubt. We have just received copies of a "General Circular" and "Circular No. 1," which contain full information on all points in respect of which inquiry would naturally be made by those who are about to seek a home in either of the British colonies; and as among this class there will probably be some belonging to our own profession, we think it well in this place to call attention to the important work being carried on by the office in question.

METROPOLITAN CHARITIES.

THE editor of the Classified Directory of the Metropolitan Charities gives some statistics for the past financial year. The Bible and Book Societies have an approximate income of £299,460; Home and Foreign Missions, of £1,683,706; Hospitals for the Blind, Deaf and Dumb, the Incurables, and Idiots, £198,436. The next group interests us much General Hospitals receive £283,439; Special Hospitals £264,044. It will thus be seen that Special Hospitals receive only some £20,000 less than General ones. Of these the most favoured are Hospitals for Women and Children, which get £70,607; and Hospitals for Consumption, which receive £59,261. Convalescent Institutions receive £48,795. There are 158 Pensions and Institutions for the aged, representing £442,685; 98 Institutions for Education, receiving £428,529. The Institutions enumerated are 1024, and their united income is £4,680,654.

COLLECTIVE INVESTIGATION OF VERRUGA.

THE Lima Academy of Medicine has issued the following collective investigation card in the hope of clearing up the etiology and pathology of the obscure but terrible disease "verruga," with which, it will be remembered, a Peruvian student inoculated himself some months ago, with a fatal result:—(1) In what regions of Peru, and up to what limits, does verruga exist? 2. At what height above the sea does verruga commence, and to what elevation does it extend? 3. Does it exist in other localities besides Peru? 4. Did it exist before the Conquest, and can the disease described by Zárate and Herrera refer to it? 5. Climatology of places where it is rife. 6. Analytic researches on the air and water of such places. 7. Etiology and symptomatology of verruga. 8. Pathological anatomy of verruga and microscopical studies of the microbe, considered by Izquierdo to be pathogenic. 9. Transmissibility of verruga and the modes in which transmission is effected. 10. Incubation of verruga. 11. Its relation to or identity with "Oroya fever." As verruga is but little known, and is undescribed in most text-books, it may be well to add that a paragraph on the subject appeared in THE LANCET of Jan. 9th, 1886, in which it is stated that the disease is "febrile and characterised by anæmia and by the appearance of red tubercles of variable size on the cutaneous surface of the body." It is mentioned in Dr. Pye-Smith's chapter on Skin Diseases in Fagge's Principles of Medicine as probably synonymous with yaws, and with the disease known as "pian" in Java, also as being possibly related to "parangi," which is endemic in Ceylon.

AN EPIDEMIC OF PNEUMONIA.

A SOMEWHAT remarkable epidemic of pneumonia is reported as having occurred in the Hexham rural sanitary district. The outbreak mainly affected Wylam, and Dr. Foulis reported to Dr. Maclagan, the medical officer of health, that the disease was epidemic in character, and that although some adults had been affected, its incidence was mainly upon children. Already the cases have exceeded a hundred in number, but when the report was received no fatal attacks had occurred, although some of the cases were very severe. All classes, irrespective of social status, had been affected; and it has been locally suggested that the weather, which is referred to as having been remarkable, had had some influence in bringing about the epidemic. We hope to learn more of the conditions under which the disease occurred.

ABSORPTION OF CORROSIVE SUBLIMATE BY THE SKIN.

DR. KOPFF states in the *Przeglad lekarski* that, having made seven experiments with careful analyses according to the methods of Schneider, Schridde, and Lehmann, with the view of determining the power of absorption possessed by the skin for corrosive sublimate, he has found that healthy skin can absorb small quantities from aqueous solutions containing from 1 to 2 per cent. of the salt. The quantity absorbed, which, however, is never large, seems to depend mainly on the degree of concentration of the solution. The chloride of mercury is also invariably excreted very soon after it has been absorbed.

A CHEMIST CENSURED FOR MEDICAL PRACTICE.

DR. C. W. ILIFFE, coroner, at Bedworth, has just had before him and a jury a bad case of medical attendance by a chemist on a child four years old. The chemist visited the child eight or nine times, between Dec. 8th and 17th. The case was certified by him to be one of quinsy. The child finally died. At the inquest, the chemist, Mr. A. Homer, gave his opinion that the child died not from the bursting of the quinsy, but from congestion of the lungs. Half an hour before death he said he saw no danger. The case is aggravated by the fact that it was not the first of the kind, and that Mr. Homer had had several previous warnings from the coroner that in the event of another such case an inquest would be held. Nor is his conduct excused by his statement that he had sat for "medical examination, but had failed to get his diploma," or by the production of thirty testimonials. The father was a responsible tradesman in the town. It is to be regretted that he did not get proper advice. But Mr. Homer's conduct had misled him. He said he had always looked on Mr. Homer as one of the doctors of the place, "as he was constantly practising." The jury found that the deceased died from asphyxia by the bursting of a quinsy, and that Mr. Homer has committed a breach of the law by attending, prescribing, and giving a certificate of death. Here their kindness came to the rescue, and they ended the verdict by expressing a hope that the

Digitized by Google

penalty of Mr. Homer's conduct might be waived if he gave a written undertaking that he would not in future, under any circumstances, infringe the law, which undertaking he gave. The coroner's remarks were at once severe and just, and his determination will not be misunderstood because he concurred in the lenient suggestion of the jury. Perhaps the Apothecaries' Society should be stayed by the same consideration; otherwise, the case is eminently one for their action.

"PLACES OF STUDY" AND THE CONJOINT EXAMINATION.

IT may not be inopportune to again call the attention of candidates rejected by the Conjoint Examining Board in England to a resolution passed last month by the Council of the Royal College of Surgeons of England recognising Mr. Thomas Cooke's School of Instruction in Anatomy and Physiology as a "place of study" for candidates rejected at the second examination of the board. This official recognition of Mr. Cooke's School after he has laboured for some fifteen years in the advancement of medical education is well deserved, and it cannot be too widely known amongst rejected candidates that the three or six months' additional work which they are required to do can now be performed under the tuition and supervision of Mr. Cooke, of whose services beyond doubt, many will find it convenient and advantageous to make use.

THE RECENT EXPLOSION AT PORTSMOUTH.

A SERIOUS gas explosion occurred on the evening of the 2nd inst. at Cambridge Barracks, Portsmouth, occupied by the 2nd Battalion, Worcestershire Regiment; four men being killed, and eighteen injured and admitted to Station Hospital. Both at the barracks and hospital the medical officers were engaged from 9 P.M. until 6 A.M. the following morning, and we believe that all that skill and attention could do was done for the unfortunate sufferers. There have been two deaths out of those transferred to hospital; one with internal hæmorrhage from rupture of spleen and right lung, and the other from multiple injury after amputation of leg. The remainder, with the exception of one case of extensive injury of the face and head, are doing well.

SCARLET-FEVER EPIDEMIC AT WIMBLEDON.

WE have elsewhere incidentally referred to an epidemic of scarlet fever in Wimbledon and Merton. The disease has appeared suddenly, and within the period of a few days only some 400 persons have been attacked, all classes being affected. There is reason to believe that the epidemic is due to the communication of the infection by means of milk. It is locally stated that a medical inspector from the Local Government Board is about to institute a complete inquiry into the subject.

BEGGING CHILDREN.

We have before had occasion to comment upon the barbarous custom of using young children for begging purposes during such severe weather as we have lately experienced. A practice which would be criminal under any conditions appears in its worst aspect when its helpless and miserable [illegible] so cruelly exposed. Its inhumanity is further aggravated in some cases by the fact that these children are not the offspring of those whom they accompany, but hired as objects of commiseration to impose upon the charitable. Even where the parentage is undoubted, the risk of vital injury to the child is not less. We [illegible] desire to make allowance for the distress of [illegible] destitution resulting from [illegible] the interests of the children must be regarded, and we must look to the police to find some shelter for at least the infant section of the begging poor.

CHOLERA IN CHILI.

ACCORDING to a despatch from Valparaiso, dated the 31st ult., some cases of cholera have been reported in Chili. This is not the first occasion since the commencement of the last European epidemic that the occurrence of the disease in South America has been noted.

FOREIGN UNIVERSITY INTELLIGENCE.

Kharkoff.—Dr. Shchelkoff, Professor of Physiology, has been appointed Emeritus Professor.

Kieff.—Dr. Mering, Professor of Special Therapeutics, has been reappointed for five years.

Königsberg.—Professor Madelung, of Rostock, has declined the invitation to the vacant chair.

Rostock.—The Mecklenburg Government has promised to supply Professor Madelung with adequate material for teaching purposes, and by this means induced him to decline the call to Königsberg.

St. Petersburg.—The following names are mentioned in connexion with the vacant chair of Clinical Surgery:—Dr. A. Beltsoff, Dr. E. Pavloff, Dr. Kusmin of Moscow, and Dr. Nasiloff, Professor of Operative Surgery in St. Petersburg, who is, as stated last week, temporarily fulfilling the duties.

Dorpat.—Dr. Rudolph Kobert, Extraordinary Professor of Materia Medica, Dietetics, and the History of Medicine, has been appointed Ordinary Professor. Dr. Carl Schmidt, Professor of Chemistry, has been reappointed for five years.

Zurich.—The death is announced of Dr. F. Horner, Professor of Opthalmology.

A REPORT has been presented to the Council of Health of the Seine on the subject of the water-supply of Paris. The following are the recommendations of the report:—To hasten the works for bringing in water from the new springs acquired by the city, and to impose on owners of house property the obligation of subscribing for the spring water; to dispense with the water from the Ourcq for the private service; to use Seine water, as far as possible, exclusively for cleansing purposes; to hasten the construction of appliances for purifying the Seine water; and to erect drinking fountains supplied with spring water at the entrance to all the barracks in the city, without prejudice to the negotiations in hand for supplying the interior of these buildings.

THE *London Gazette* of the 4th inst. contains an announcement of the fact that the Queen has been pleased to grant Edward Divers, M.D., F.R.S., Principal and Professor of Chemistry at the Imperial College of Engineering, Tokyo, permission to accept and wear the insignia of the Order of the Rising Sun of the Third Class, which His Majesty the Emperor of Japan has conferred upon him in recognition of his services whilst actually and entirely employed beyond Her Majesty's dominions in His Imperial Majesty's service.

ACCORDING to the *Publishers' Circular* the numbers of new books and new editions published in 1886 in the three divisions of Theology, Law, and Medicine were as follows: Theology, 616 new books and 136 new editions; Law, 18 new books and 15 new editions; Medicine, &c., 114 new books and 57 new editions. The number of novels, tales, and other works of fiction published during the twelve months was 755, exclusive of new editions of 214 works which had appeared in previous years.

THE *Provincial Utrechtsch Genootschap van Kunsten en Wetenschapen* (Utrecht Association of Arts and Sciences) offers 300 gulden for the best research on the Action of Purgative Salts on the Intestine, compared with the Action of Senna and Calomel. The essays (which may be in English) are to be sent to the secretary, Herrn R. Melvil, Baron van Lynden, Utrecht by Dec. 1st, 1888.

THE death is announced of Deputy Surgeon-General Richard Wolseley, M.D., who was killed by a fall from his horse at Meerut a few days since. The deceased officer was a brother of Lord Wolseley.

A PIECE of sacred music has recently been composed and performed in private by one of the professors of the medical faculty of Madrid, which is highly spoken of by the press of that capital.

NEWS has been received of the death of Señor Don Dr. Sandalio Pereda, member of the Council of Public Education, and for more than twenty-five years Professor of Natural History in the Institute of San Isidro, Madrid.

THE Order of Companion of the Indian Empire has been conferred upon Brigade Surgeon Henry Elmsley Busteed, M.D., late Assay Master of the Calcutta Mint.

MR. THOMAS SALT, M.P., has been elected to be permanent chairman of the Commission in Lunacy.

STATISTICS RELATING TO MEDICAL STUDENTS DURING THE QUINQUENNIUM 1871-75.

THE facts about medical students which have been elicited by the further investigations of the Statistical Committee of the Medical Council deserve more attention than we have hitherto been able to give them. The Report of the committee is an important document, and will well repay the attention of those who take an interest in medical education. It will be understood that the statistics of this Report (the third) of the Statistical Committee refer to the quinquennium 1871-75 as a whole. The investigation includes the tracing of 6403 students who were registered in this quinquennium. The number gives an annual average for these five years of 1280·6, an average which in the corresponding five years of this decennium is exceeded by no less than 651. It is interesting to notice the chief *Places of Study* arranged according to the percentage (of the total number of medical students) registered as entering at each. They are as follows:—University of Edinburgh, 13·21 per cent.; University of Glasgow, 8·70 per cent.; University College Hospital, 5·53 per cent.; St. Bartholomew's Hospital, 5·48 per cent.; Guy's Hospital, 5·26 per cent.; University of Aberdeen, 4·39 per cent.; School of Physic, Ireland, 4·28 per cent.; Queen's College, Belfast, 4·11 per cent.; Ledwich Medical School, Dublin, 3·90 per cent.; St. Thomas's Hospital, 3·50 per cent.; Queen's College, Cork, 3·39 per cent.; Royal College of Surgeons, Ireland, 2·61 per cent.; Queen's College, Galway, 2·59 per cent.; King's College Hospital, London, 2·47 per cent.; St. George's Hospital, 2·41 per cent.; London Hospital, 2·12 per cent.; Queen's College, Birmingham, 2·00 per cent.; Liverpool Royal Infirmary, 1·89 per cent.; St. Mary's Hospital, 1·67 per cent.; Owens College, Manchester, 1·55 per cent.; the Catholic University Medical School, 1·53 per cent.; Leeds Medical School, 1·52 per cent.; University of Cambridge, 1·33 per cent.; Middlesex Hospital, 1·28 per cent.; Manchester Royal Infirmary, 1·20 per cent.; Charing-cross Hospital, 1·05 per cent.; Addenbrooke's Hospital, Cambridge, 1·03 per cent.; Bristol Medical School, 0·95 per cent. But Part II. of the Report shows that of the 6403 students registered as entering the various places of study in the quinquennium, 1871-75 no less than 1931, or 30.16 per cent had not up to 1885 registered any qualification. This is a sad history of miscarriage, and gives importance to the question of a visitation of the schools. There are tables (Table II. and Table II.A) giving the *percentages of failure to qualify* of those beginning their medical studies at the more important schools. These failures, summarily, are, in England, 27·50 per cent.; in London, 26·28 per cent.; in the provinces, 29·70; in Scotland, 30·98 per cent.; in Ireland, 34·33 per cent.; abroad, 44·12 per cent. It would be wrong to attach too much importance to these statistics of failure. The significance of them must be a complicated matter. But they will excite a wholesome criticism, out of which light and good will come. As a matter of figures, in London, for example, the largest percentage of failures to pass was in those who began their studies at St. Bartholomew's, and the smallest in those who began at Westminster. In Scotland the largest proportion of failures to qualify (34·62 per cent.) is in those who began their medical studies at Anderson's College, Glasgow; the smallest, in those who began in the University of Glasgow. In Ireland the smallest proportion of failures (25·00 per cent.) was in those beginning medical study at the City of Dublin Hospital; the largest, in those beginning at Ledwich Medical School, Dublin. Of the 6403 gentlemen whose medical education began in some year of the quinquennium 1871-75, and whose destinies have been the subject of so much attention by the Statistical Committee, 4472, or 69·54 per cent., have at some time *appeared* in the *Medical Register* as Practitioners. Of these 50 per cent. were from places of study in England; 33 per cent., or one-third of the practitioners, began in London schools. The school which has the satisfaction of having the largest proportion of its students proceed to obtain a qualification is Charing-cross, 88·06 per cent. having so succeeded. Addenbrooke's Hospital, Cambridge, has the smallest proportion (48·48).

We come next to a class of students who are regarded with much disfavour by the corporations—i.e., those who content themselves with *One Qualification*. There are 607 gentlemen who up to the end of 1885 had not registered more than one qualification. Of these, 42 per cent. took the diploma of the English College of Surgeons. Mercifully for the corporations, of the 6403 students registered in the quinquennium 60·36 per cent. have already become doubly qualified. This is characterised by the Statistical Committee as "one of the most important facts" brought out by the investigation. St. Thomas's Hospital heads the list of those getting a double qualification, and Addenbrooke's Hospital closes it. The next point elucidated by the statistics is of real interest—the *length of time* taken by students of the quinquennium to qualify. No less than 153, or 3·39 per cent., managed to shorten their curriculum. Eighteen students accomplished the feat of qualifying in the same year they began their studies; one came from London, three from Scotland, thirteen from Ireland, and one from abroad.

The Irish seem to know better than English or Scotch students how to get through in less than the prescribed time, and it is desirable that light should be thrown on their way of doing it. Thus of 151 students who accomplished this feat, 25 were from England, 21 from Scotland, and 105 from Ireland. The average interval taken to get qualified is FIVE years, and it is noticeable that those who never get more than a single qualification, take rather more than twelve months over the time taken by those who become doubly qualified. Our space being exhausted, we must pass over Part VII. of the Report, which deals with the interval between the two qualifications in those doubly qualified, and Part VIII. on the various methods of qualifying. We end by a notice of the important phenomenon described as the *Migration of students out of their own Division in search of licences to practise*. Some very interesting facts came out in Table XI. From this it is seen at a glance that of the 997 students of the *Quinquennium* who qualified at the Royal College of Physicians, Edinburgh, 502, or over 50 per cent., came from places of study in England, or, putting it differently, that, of 2262 English students of the quinquennium who became registered practitioners, 22·19, or well on to a quarter, qualified at the Royal College of Physicians of Edinburgh. From Table XI.A it appears that, of 4453 qualified practitioners, the total outcome of the students of this quinquennium, no fewer than 1227, or 27·55 per cent., went for one or other of their diplomas to another division than that in which they registered as students. This fact

Digitized by Google

tains where geographical convenience does not explain it; thus, no less than 56·81 per cent. of the students of the Bristol school went to Scotland for their qualification. A few Scotch and Irish students qualify in England. But this is nothing to the number of English and Irish students who take one or both of their qualifications in Scotland. Of those students who qualified in Scotland, no fewer than 41·7, or 48·0 per cent., came from other divisions of the kingdom. The Scotch bodies whose examinations were most seductive to the English are, not those of the Edinburgh University, but the Royal College of Physicians of Edinburgh, the College of Surgeons, the Faculty of Glasgow, and the University of Aberdeen. We must for the present leave the Report at this point, commending it and its tables to the study of all medical educationists, and thanking the Statistical Committee for the tables, and especially for the text which explains them. The facts brought to light are of high importance in view of the discussions going on for securing for England her fair share of work in giving degrees to her own students. The Report abounds in other information, which we may give our readers at a future time.

THE FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

THE following is a copy of the petition now being circulated by the Association of Members of the Royal College of Surgeons for signature by the Members of the College throughout the kingdom:—

To the Queen's Most Excellent Majesty in Council.

The humble petition of the undersigned Members of the Royal College of Surgeons of England showeth:

That whereas a petition has been prepared for presentation by the President and Council of the Royal College of Surgeons of England, praying for a supplemental Charter, or alterations in the existing Charters previously granted to the said Royal College, your humble petitioners approach your Most Gracious Majesty respectfully to point out that by the present Charters the Members of the said College (who are in proportion to the Fellows as 14 to 1) have no status of any kind in connexion with the governing body.

Your petitioners most humbly submit that it would be both equitable and politic that the Members should have a voice in the conduct of a corporation of which they are, and always have been, numerically and financially the mainstay. At present the Council, elected by the 1200-Fellows only, deals absolutely with the interests, property, and moneys of the College, whilst 16,000 Members are wholly unrepresented.

Your petitioners do, therefore, most earnestly pray that before granting any Charter or supplemental Charter to the said Royal College, the present position of your petitioners may receive your Majesty's gracious consideration for such provisions as will create and secure for the Members (who so largely contribute to the prestige and welfare of the said College) the right of representation and other privileges which should belong to the Members of a corporate body; further, that an inquiry may be instituted into the constitution of the Council, the management of the College, the conduct of examinations, and the expenditure of the College funds.

Finally, your petitioners very humbly pray that in the event of no petition for a Supplementary Charter or otherwise being presented by the Council of your Royal College, your Majesty may be graciously pleased, in your wisdom, equity, and discretion, to sanction and provide for certain alterations being made in the present existing Charter so that it may contain such provisions as are hereinafter mentioned:—1. That all Members of a certain number of years' standing, to be determined by your Gracious Majesty, may, after having been registered, conjointly with Fellows, exercise the privilege of electing the Council. 2. That a certain proportion of the Council may consist of Members. 3. That the period of office of members of the Council be considerably shortened. 4. That Members and Fellows be permitted to vote by voting papers. 5. That no fees of any kind be paid to any College fund by Fellows or Members on their election to office. 6. That the Council prepare a yearly report, together with an account of income and expenditure of the College funds duly audited by a public accountant, which, after its submission for approval to the Fellows and Members (annually summoned for this purpose by the President of the College), shall, on adoption, be required to be published in the medical journals. 7. That enlarged power may be given to the Council to suspend or revoke the licence of any Fellow or Member on proof of discreditable conduct, whether professional or otherwise.

And your petitioners, as in duty bound, will ever pray, &c.

THE HIGH ALTITUDE TREATMENT OF PHTHISIS.

(FROM A SPECIAL CORRESPONDENT.)

The Alpine Health-Resorts—Davos, Wiesen, St. Moritz, The Maloja; Present Condition of these Sanatoria; Recent Results of Treatment there; Indications and Contra-indications for and against the adoption of the Method of Treatment.

THE high altitude treatment of phthisis—the *Altenkur* or *Luftkur* of German writers—has already attained so much popularity, and contains such promise for the future, that your readers will be interested in learning the present position of this method of practice and the nature of the results now being obtained. The following remarks are based on personal observations made in the Davos valley and the Engadine.

Among the high altitude sanatoria of the Alps Davos is still *facile princeps*. It was the reputation acquired by this little Alpine village which first gave the impetus in Europe to the mountain treatment of consumption, and it still retains its early popularity and pre-eminence over similar health-resorts. Twenty years ago Davos was one of the most secluded valleys in the Alps, with a population of barely one hundred souls, rarely or never visited by tourists, who found little or nothing to attract them in its somewhat sombre scenery. Now the valley boasts a winter population of 3000 (nearly one-half of whom are invalids), six or seven first-class hotels and numerous smaller ones, and some nine or ten resident medical practitioners. Its growth has been rapid, and in the opinion of some competent authorities it cannot proceed any longer unchecked, without the inevitable forfeit of that perfect purity of the atmosphere to which Davos undoubtedly owes no small portion of its fame.

The main features of the Davos climate, and their adaptability to certain morbid states, have lately been dwelt upon in your editorial columns. The meteorological conditions include aerial rarefaction, great purity of the atmosphere, low relative humidity, coldness of the air, with much brilliant sunshine and a high range of sun-heat, and comparative immunity from wind, fog, and miasmal emanations. These characteristics are more or less common to all the high Alpine resorts, but it is to its admirably sheltered position and the consequent stillness of the atmosphere that Davos mainly owes its indisputable pre-eminence over rival health stations. The valley, while singularly destitute of the Alpine charm of scenery, is marvellously adapted to the needs of the invalid in this regard. During his winter sojourn he must have sunshine and shelter, and it is obvious that these two indications are to a certain extent incompatible. An open valley like the Engadine is sure to be wind-swept, while a deeply secluded valley will lack the necessary *quantum* of sunshine. Davos admirably fulfils the condition of necessary mean between undue exposure and excessive shelter. The valley is protected on the north by the elevation of the Davos-Kulm, and on the south it terminates in the narrow and tortuous gorge of the Landwasser, so that any strong valley current of air is impossible. While thus protected from wind, Davos receives a large amount of sunshine, owing to the fact that the valley lies open—varying in breadth from half a mile to a mile,—and the surrounding mountains are neither very lofty nor do they form a continuous investment.

Opinions differ as to what constitutes the most important factor in the unquestionably beneficial influence which the Davos climate exercises upon consumption. Some good authorities regards the purity of the air, consequent upon the sparseness of the population (with a correlative immunity from morbific germs), as the main point, and hence they view with great apprehension the yearly increasing ingress of consumptives to the once quiet valley of Davos. Others, again, think that the main point is the aerial rarefaction, leading to increased respiratory activity and consequent expansion of the

Digitized by Google

thorax. Under this head I may mention that Dr. Ruedi, whose name is already quite familiar to the profession in England, reports that of 600 consumptives under his care distinctive thoracic expansion took place in no less than 584 cases. Other authorities, again, attribute the beneficial results obtained at Davos to the *tout ensemble* of tonic conditions promotive of appetite, sanguification, and improved nervous tone.

The accommodation at Davos is in the main surprisingly good. The hotels most frequented by English visitors are the Belvedere, the Angleterre, the Victoria, and the Buol—all first-class; and the food-supply leaves little to be desired. In the depth of winter fresh green vegetables are somewhat scarce, but in other particulars the hotels are as well provided as in the most favoured resorts for consumptives. The rooms are fitted with double windows, and are heated by stoves. The "stove question" is one of the controversies at Davos, and the advantages and defects of this method of heating are much canvassed. On the one hand, it is unquestionable that so wasteful and inefficient a method as our open fireplaces would be powerless to cope with the extreme cold of Davos; while, on the other hand, it cannot be denied that the stoves unduly absorb the moisture of the air, and are useless for promoting ventilation. On the whole, the necessity for spending a large proportion of time in stove-heated apartments is a serious (and apparently an inevitable) drawback to the high-altitude treatment.

All information tends to prove that life under the novel climatic conditions which prevail at Davos, so far from involving serious hardship, is, on the contrary, most enjoyable. Day after day the sun shines with cloudless splendour, perfect stillness reigns in the valley, while the keen bracing air and the dry crisp snow invite to exercise and pleasurable activity. Almost all invalids, except the most prostrate and utterly hopeless cases, profess to enjoy the Davos life; and one encounters in the hotels not a few persons in perfect health, who, having once visited the high altitude resorts, return again and again to quaff fresh draughts of that subtle intoxicant, the air of the Higher Alps. Skating, tobogganning, and sleighing are among the most favourite amusements, and are freely indulged in. Whether this free participation in vigorous out-door amusement is a prudent proceeding on the part of consumptives is another point about which the visitor to Davos finds a lively controversy raging. The English invalids incline to these methods; the Germans regard them with some suspicion. It strikes the stranger to Davos that the alleged cases of mischief which are said to have followed this vigorous therapy are probably in a large measure attributable rather to dancing, theatricals, and other amusements carried on in heated and overcrowded assembly-rooms. Davos has already shared the usual fate of the popular health-resort, and advertises its concerts, theatricals, and similar meretricious attractions—as if the consumptive should seek such pleasures rather than regard them as a snare to be studiously shunned. No one can doubt that the early fame of Davos owed much to simplicity of manners and immunity from so many of the temptations of life.

There are very few days at Davos throughout the winter season upon which the invalid cannot take out-door exercise. Even during a heavy snowfall walking is possible and pleasurable, as the snow is perfectly dry and can be shaken off as it falls. During the day the sun heat is so great that invalids sit for hours without furs or other extra muffling upon the hotel balconies enjoying the grateful warmth, while at the same moment the shade temperature is far below freezing-point. In a moist atmosphere this discrepancy between sun heat and shade temperature would involve a dangerous amount of chill, but all authorities agree that chill, with its usual consequences of bronchial catarrh, pneumonia, &c., is extremely rare at Davos. The explanation is to be found in the dryness of the air, which renders it so promotive of cutaneous and mucous transpiration. As illustrating this peculiar feature of the Davos climate, the writer may cite an incident related to him by Mr. Symonds, the eminent critic and poet, who may be regarded as the parent of whatever reputation Davos possesses with the British public. Mr. Symonds was sitting one day upon his balcony engaged in literary work, and enjoying the pleasant sunshine. A cup of coffee stood on the table beside him. He chanced to stand up for a few moments in such a position as to intercept the impact of the sun's rays upon the table, and, on turning to finish his coffee, he found it frozen into a solid mass of ice. Here ar illustrated some of the essential peculiarities of the Davo climate—intense coldness of the air combined with a stillness o the atmosphere which makes that cold practically unfelt, an a powerful sun heat which makes us hesitate whether to clas the climate as hot or cold. Stranger still is the fact that i the evenings many invalids are able with impunity to leav a room heated to 60° and go out into the wintry night witl the thermometer at zero. The nights at Davos are ofte hardly less brilliant than the days. The moon rides higl through cloudless skies, the air is perfectly still, and so littl is the cold felt that one can hardly credit the low reading of the thermometer. Frost-bite occasionally occurs a Davos, but is rare, and hardly ever leads to serious results.

Davos is just now threatened with a railway, but the project, although favoured by the communal authorities is viewed with much suspicion by those who are jealous fo the preservation of the simple manners and pure air which laid the foundations of the reputation of this *altenkurort*. The railway is objected to, not merely because the smoke would add to the sources of air contamination, but because such increased facilities of communication would be likely to augment with perilous rapidity the yearly-increasing advent of consumptives. This leads us to consider the most burning of all the controversies at Davos—viz., the question of overcrowding. Mr. Symonds gave the first warning on this subject some years ago in the columns of the metropolitan daily press, and his views are shared by Dr. Ruedi, Mr. Arthur William Waters, and other competent authorities. At first sight, the visitor to Davos in inclined to be sceptical about the dangers of overcrowding in a valley twenty miles long by half a mile to a mile wide, whose population has reached only to the figure of 3000. But when he has fully appreciated the peculiarities of the Davos climate, he begins to realise that such fears are far from being groundless. The reasons why, with a comparatively scanty population, Davos is threatened with the evils of overcrowding are as follows:—

1. The stagnation of air during the winter, and the consequent accumulation of the products of combustion, putrefactive particles, &c.
2. The large amount of fuel consumed owing to the cold.
3. The nature of the invalid cases, every consumptive being a focus of air contamination.
4. The impossibility of thorough ventilation owing to the cold.
5. The pulverisation of sputum owing to the dryness of the atmosphere, and its consequent dispersion through the air.
6. The presence of numerous cattle, and the accumulation of their *dejecta*.

This last source of contamination is one which admits of ready removal, and the inhabitants of Davos would do well to give their attention to this matter.

No doubt some of the above sources of contamination are minimised by the dryness of the air and its tendency to check putrefactive change, but looking impartially at the whole question, I am decidedly of opinion that if ever Davos is transformed into a densely populated valley its virtues as a sanatorium will have become mere matters of history.

Efforts are now being made, especially by Mr. Waters, to suggest some alternative sanatorium. Of the virtues of Wiesen, St. Moritz, and the Maloja I propose to speak in a subsequent article. Mr. Waters thinks a village near Schuls in the Engadine offers special advantages, and attention has lately been drawn to the merits of the beautiful and secluded Valley of Arosa.

The sanitation of Davos, which not long ago, was most defective, has been thoroughly rectified—thanks to the vigorous protests of Mr. Symonds,—and may now be pronounced excellent.

ADULTERATION IN PARIS.—In spite of the keen watchfulness of the authorities, adulteration is still extensively practised in Paris. Out of 645 samples of wine examined in November last, 450 were declared injurious; out of 88 samples of beer 5 were bad; and of 18 samples of spirits only one was condemned. More than half the samples of water were reported to be dangerous, and 80 out of 370 specimens of milk were placed in the same category. Out of 81 loaves of bread 30 were worthless, and out of 22 specimens of wall paper only 5 were good. Coffee was very little adulterated, and the butter was also reported to be fairly satisfactory.

"VALUE OF MEDICAL EVIDENCE IN LIFE ASSURANCE."

THE following communication has been received for publication:—

"Mr. Chisholm presents his compliments to the Editors of THE LANCET, and begs to forward to them a copy of the paper read before the Institute of Actuaries, to which reference is made on pages 1093 and 1094 of the issue of THE LANCET of December 4th. Mr. Chisholm has not seen the article in the *Scottish Banking and Insurance Magazine*, which forms the basis of the note in THE LANCET, but he thinks that the statements in that article may have misled the Editors of THE LANCET as to the object of Mr. Chisholm's paper. Mr. Chisholm does not hold the opinion imputed to him that it is either possible or desirable to dispense with the test of medical examination in the general practice of life insurance, and his paper was written rather with the opposite view of discussing measures for making medical examinations more effective. There are cases—the insurance of the lives of a great number of *employés*, for example—in which actuarial opinion is favourable to the idea of dispensing with medical examination, but these are necessarily rare in their occurrence, and Mr. Chisholm, at the outset of his paper, endeavoured to define the conditions under which alone such dispensation might be allowed. The quotation of the words embodying this opinion without qualifying conditions, and leaving it to be understood that a course which might be followed on rare occasions should be treated as of universal application, amounts not to a representation, but to a travesty of Mr. Chisholm's views. The Editors of THE LANCET will no doubt deem it right to give equal prominence to this disclaimer as to the original notice that appeared in their journal, and it is hoped that they will lend the weight of their high authority to the promotion of a common understanding (which the eminent physicians who act as the chief medical advisers of our life insurance companies, do so much to encourage) between medical examiners and actuaries as to their respective spheres in the delicate and difficult task of assessing life risks—a task which it is not possible for either the one expert or the other completely to undertake by himself."

We are glad to learn that the opinion attributed to Mr. Chisholm as to the doubtful advantage of a medical examination in cases of life assurance is incorrect. We cannot but regret, however, that he was not more clear in the statement of his views, for we find that two of the gentlemen who were present at the reading of his paper understood him to hold the opinion attributed to him in the *Scottish Banking and Insurance Magazine*. Dr. Selfe Bennett said that "Mr. Chisholm had praised past times, and looked back with regret upon the old days when the proposer simply went before the board of directors, who asked him a few questions and accepted or declined him..... They were not likely to get statistics such as the author hoped for, to an extent and sufficiently reliable to enable an actuary to step in and dispense with the doctor's services." And, again, Dr. Tirard said "that Mr. Chisholm appeared to take two opposite views: first of all, that they ought to do without medical examination at all; and secondly, that they ought to make the medical examinations much more strict in their work than they have hitherto been." It is satisfactory to be informed by Mr. Chisholm that he does not think it either possible or desirable to dispense with the medical examination in cases of life insurance.

CHRISTMAS FESTIVITIES IN THE HOSPITALS.

Great Northern Central Hospital, Caledonian-road.—The usual Christmas entertainment was given to the patients in this institution by the members of the Ladies' Association in connexion therewith, and to those inmates who were able to attend a concert of vocal and instrumental music was given. A Christmas-tree was provided for the children who were, or had been during the year, inmates of the hospital, and presents of warm clothing were also distributed.

Paddington-green Hospital for Children.—On the 29th ult. a Christmas entertainment was given to the in-patients and convalescents at this institution. The proceedings, which began with a Punch and Judy show and a magic lantern exhibition, were concluded by vocal and instrumental music, and an exhibition of dogs.

Brompton Hospital.—Christmas at this institution was inaugurated by a Confirmation held by the Bishop of London in the chapel of the hospital on the 23rd ult., at which fifteen of the patients were presented. On the 25th carols were sung, and after service in the chapel extra rations of seasonable food were provided for the inmates. In the evening an entertainment of vocal and instrumental music was given. On the 28th carols were sung by a trained choir, and on the 30th ult. a Christmas tree was provided.

London Hospital.—The annual festival of the children's Christmas-tree was celebrated in this institution on the 4th inst., when toys and other suitable presents were distributed to the juvenile patients, who number about 130 Previous to the distribution an entertainment was given.

WILLS OF MEDICAL MEN.

THE will and two codicils of Archibald Gordon, M.D., C.B. formerly Inspector-General of Hospitals at Bombay, then of Halmyre, Peeblesshire, N.B., but late of 76, Cornwall-gardens, South Kensington, who died on August 3rd last, at West Hoathley, Sussex, were proved on Dec. 8th, by Mrs. Mary Preston Gordon, the widow, and Mr. Charles Bowman Logan, the executors, the value of the personal estate in the United Kingdom amounting to over £17,000. The testator gives his household furnishing, plate, books, pictures, and plenishing of every kind to his wife absolutely; and £200 to his executor, Mr. Logan. The residue of his real and personal estate he leaves upon trust for his wife for life, she maintaining and educating children residing with her; and at her death for the whole of his children by her, share and share alike.

The will of Richard Sharpe, M.D., formerly of Cheshunt, Herts, but late of The Ferns, Oakleigh-road, Whetstone, Middlesex, who died on Nov. 9th, was proved on Nov. 27th by Mr. Henry Perceval Mackrell, and Mr. Ernest Rolls Sharpe, the son, the executors, the value of the personal estate exceeding £9000. The testator makes some specific bequests to his wife and children; and leaves the remainder of his furniture and effects and £4000 to his wife for life or widowhood. The residue of his property he gives to all his children equally.

The will of Joseph Seaton, M.D., late of Halliford House, Sunbury, Middlesex, who died on Sept. 30th last, was proved on Dec. 2nd by John Joseph Joscelyn Seaton, M.D., the son, and Mr. George Thomas Haigh, the executors, the value of the personal estate being over £4500. The testator bequeaths a picture to his said son, and a legacy to a granddaughter. As to the residue of his real and personal estate, he leaves one-fourth to or upon trust for each of his children, Ernest William Attree, Katherine Jane, and Robert Winslow; and one-fourth upon trust for his daughter, Mrs. Ellen Dickinson, until she shall succeed to certain property, and then to be divided between his three last-named children.

The will of Mr. Joseph Sampson Gamgee, Surgeon, late of 22, Broad-street, Birmingham, who died on Sept. 18th last, has been proved at the Birmingham District Registry by Mrs. Marion Gamgee, the widow, and one of the executors. The testator leaves all his real and personal estate upon trust for his wife for life or widowhood, and then for his children in equal shares.

The will of John Burke, M.D., late of Hatfield, Herts, who died on Nov. 9th, was proved on Dec. 2nd by Mr. Arthur Edmund Sharp, the sole executor. The testator gives all his real and personal estate to Mary Ann Charlotte Chiffelle

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Henry Boddington, of The Cove, Silverdale, Lancashire, and of Strangeways, Manchester, brewer, £1000 to the Manchester Royal Infirmary and Dispensary, £250 each to St. Mary's Hospital and Dispensary, Manchester, and the Salford and Pendleton Royal Hospital and Dispensary; and £150 to the Stockport Infirmary.—Mrs. Elizabeth Fisher of The Avenue, Colchester, Essex, £100 to the Essex and Colchester Hospital.—Mrs.

Mary Ann Garston, of High Pastures, Crigburth near Liverpool, £100 each to the Royal Infirmary and Children's Hospital, Liverpool.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Pancras.—The annual report for 1885 is the first one submitted to the vestry by their newly-appointed medical officer of health, Dr. J. F. Sykes, and as he only held office during a portion of the year he does not profess to deal with the district in such detail as he could have wished. Making the necessary corrections, the annual death-rate from all causes was 19·89 per 1000 living, that from the zymotic group being 2·6. Small-pox caused 63 deaths in the latter group, the outbreak being a continuance of that which commenced in 1884. As to this disease, Dr. Sykes specifies how the metropolis is to be benefited by the prompt removal to a distance of London small-pox patients by the Metropolitan Asylums Board. But this will not affect the Highgate hospital, which lies on the boundary of St. Pancras, and the influence of which on this district was shown in Mr. Shirley Murphy's last report. As to water-supply, we learn that before another year elapses the whole parish will be provided with a constant water service, except a few houses supplied by the West Middlesex Water Company. The improvement is stated to be accompanied by conditions which are regarded by the inhabitants as excessively stringent, but from a sanitary point of view the gain will be considerable. A new mortuary and disinfecting buildings are being provided. The rapid steam process of disinfection is not to be supplied, apparently on the ground of expense, both the initial cost and that of retaining the services of a skilled servant being held in view. This is to be regretted, because the alternative dry-heat system is so much more slow; and since there are many articles which cannot be thoroughly penetrated by the necessary temperature, except after the lapse of from six to eight hours, there is danger of undue haste leading to imperfect results. In a district where already some 4000 articles are sent for disinfection, we should have thought that the steam-pressure system was called for on the grounds of economy of labour and of time, if not also on the score of ultimate expense.

Birkenhead Urban District.—Allowing for increase of population, the birth- and death-rates for this borough during 1885 were 34·6 and 19·5 per 1000 respectively, the zymotic rate being 2·4. Mr. Vacher discusses at considerable length the meaning of these rates from different points of view and in relation to the different portions of the district, and he then proceeds to give details concerning each group of diseases. Of small-pox there were 24 fresh cases during the year; each was isolated. When a case came under notice the public vaccinator was immediately acquainted with the fact in order that the requisite means of protection might be afforded to those who ran the risk of exposure to infection. Under the compulsory system of notification, 1580 cases were reported. The majority were cases of measles, but scarlatina accounted for 556, typhoid fever for 38, and diphtheria for 21 cases. It is noteworthy that, although the dual system of notification by householder and medical attendant is in force, there were only nine instances of notification by householders; and Mr. Vacher also points out that the allegation so often made, to the effect that in places where notification existed the proportion of deaths from the diseases notified to cases reported would show an increase, is certainly not correct in the case of Birkenhead. In short, compulsory notification has not led to cases being hidden and left without medical attendance. There has, on the contrary, been a decided diminution in the deaths in Birkenhead, and a corresponding saving of life. There is, unfortunately, a large amount of unregistered deaths among infants, and it is almost impossible not to suspect some sinister motive as influencing this failure to seek medical help in infantile diseases. The infectious hospital, now enlarged, did good service during the year; the sanitary work included the disinfection of 696 houses and 234 parcels of clothing, and the destruction of bedding, &c., in 28 cases, the arrangements for all this work being well organised. Lodging-house inspection needs reform, for there is no night-inspector, and it is well known that without such an officer efficient control of common lodging-houses and occupiers of cellar dwellings cannot be carried out. Improved arrangements have been made for slaughtering, and the report for 1885 shows, in other respects, excellent progress.

Portsmouth Urban District.—Dr. B. H. Mumby was only appointed medical officer of health for Portsmouth towards the close of 1885, and hence he is only able to deal with such facts and figures for that year as have been brought under his notice. The birth- and death-rates were 34·5 and 19·79 per 1000 respectively, in a population of 134,659. New works of sewerage are in progress; and, referring to the position which Portsmouth formerly held in the list of English towns, as quoted by the Registrar-General, Dr. Mumby expresses the hope that, with their completion, Portsmouth will regain the place which she formerly occupied. Portsmouth is a very composite borough, and this is especially marked in the case of enteric fever. Thus at Southsea, where the sanitary arrangements of the houses are mostly on an improved and modern system, with good drain ventilation, the fever death-rate is 0·39 per 1000; whereas in Kingston, where the sanitary arrangements are not nearly so good, the rate is more than double. And, amongst the causes of enteric fever, the pollution of the subsoil by cesspits and by a faulty main sewer are specially adverted to. Such pollution must also be regarded as one of the main factors in the production of fatal infantile diarrhœa. This latter disease was also twice as fatal in Kingston as in Southsea. Under a system of compulsory notification of infectious diseases the following were heard of:—Typhoid, 762; scarlet fever, 314; diphtheria, 173; small-pox, 2; puerperal fever, 2—in all 1253. And yet only 37 patients were admitted into the infectious diseases hospital, a number so small that the institution can hardly have influenced the state of infection in the borough to any noteworthy extent. Dr. Mumby hopes the buildings will come to be more used, and he goes on to show how small are the payments demanded by the sanitary authority. We expect these payments are the main hindrance to the proper use of the hospital, and it would be well for the Town Council to consider whether it is desirable, for the sake of £53 odd, to run the risk of deterring people from seeking isolation. Over and over again it has been shown that even small payments are a hindrance; and in some places it has very properly been decided that ratepayers and their households—that is to say, those who built and who maintain the hospital—should be admitted free. Masters sending servants are required to pay 10*s.* 6*d.* a week in Portsmouth. A greater inducement to pack a maid off to her own home as soon as possible could hardly be devised. What does the master in his capacity as ratepayer pay for, if it be not the right to use the hospital for the protection of his household?

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5397 births and 4374 deaths were registered during the week ending Jan. 1st. The annual death-rate in these towns, which had been equal to 20·7 and 21·5 per 1000 in the preceding two weeks, further rose last week to 25·1. During the thirteen weeks ending last Saturday the death-rate in these towns averaged 20·3 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 16·8 in Blackburn, 17·6 in Derby, 18·4 in Sunderland, and 19·5 in Bradford. The rates in the other towns ranged upwards to 32·3 in Manchester, 32·4 in Liverpool, 35·2 in Cardiff, and 36·0 in Halifax. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 386 and 433 in the preceding two weeks, further rose last week to 537; they included 244 from measles, 90 from whooping-cough, 80 from scarlet fever, 56 from "fever" (principally enteric), 36 from diarrhœa, 30 from diphtheria, and 1 from small-pox. No death from any of these zymotic diseases was registered last week in Derby; whereas they caused the highest death-rates in Portsmouth, Halifax, Wolverhampton, and Leeds. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Liverpool,

Digitized by Google

Halifax, Leeds, and Wolverhampton; from scarlet fever in Salford, Newcastle-upon-Tyne, Bradford, and Manchester; from whooping-cough in Sunderland, Manchester, Oldham, and Huddersfield; and from "fever" in Portsmouth, Preston, Norwich, and Cardiff. The 30 deaths from diphtheria in the twenty-eight towns included 9 in London, 5 in Portsmouth, 3 in Birmingham, 3 in Birkenhead, and 2 in Newcastle-upon-Tyne. Small-pox caused one death in Portsmouth, but no death from this disease was registered in London and its outer ring, or in any of the twenty-six other large provincial towns. No case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 494, 416, and [illegible] in the preceding three weeks, rose last week to 577, and exceeded the corrected average by 35. The causes of 129, or 2·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Wolverhampton, Birkenhead, and Cardiff. The largest proportions of uncertified deaths were registered in Halifax, Sheffield, Oldham, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·0, 22·5, and 26·2 per 1000 in the preceding three weeks, was 26·0 in the week ending Jan. 1st; this rate exceeded by 0·9 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·4, and 18·5 in Perth and Leith, to 24·6 in Greenock and 32·9 in Glasgow. The 641 deaths in the eight towns last week showed a decline of 7 from the numbers in the previous week, and included 21 which were referred to whooping-cough, 16 to measles, 13 to diarrhœa, 12 to scarlet fever, 10 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and not one to small-pox; in all 73 deaths resulted from these principal zymotic diseases, against 75 and 63 in the preceding two weeks. These 73 deaths were equal to an annual rate of 3·0 per 1000, which was 0·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 19 and 15 in the previous two weeks, rose last week to 21, of which 18 occurred in Glasgow. The 16 deaths from measles, all of which were returned in Glasgow, also showed a further increase upon recent weekly numbers. The fatal cases of scarlet fever, which had declined in the preceding four weeks from 25 to 13, further fell last week to 12, which included 5 in Glasgow and 5 in Dundee. The 13 deaths attributed to diarrhœa somewhat exceeded the numbers in recent weeks; 6 occurred in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The 10 deaths referred to "fever," exceeded the number in the previous week by 6, and included 3 in Glasgow and 2 in Greenock. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding five weeks from 125 to 188, declined last week to 179, but exceeded the number in the corresponding week of last year by 36. The causes of 88, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 35·6, 29·6, and 28·5 per 1000 in the preceding three weeks, rose to 38·0 in the week ending Jan. 1st. During the thirteen weeks ending last Saturday the death-rate in the city averaged 33·7; the mean rate during the same period did not exceed 18·8 in London and 19·5 in Edinburgh. The 257 deaths in Dublin last week showed an increase of 64 upon the number in the previous week, and included 11 which were referred to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 2 to diarrhœa, and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 23, 22, and 21 in the previous three weeks, further declined last week to 17; they were equal to an annual rate of 2·5 per 1000, the rates from the same diseases being 2·6 in London and 1·2 in Edinburgh. The 11 fatal cases of scarlet fever exceeded the numbers returned in recent weeks; whereas those referred to "fever" and diarrhœa showed a further decline. Thirteen inquest cases and 10 deaths from violence were registered; and 84, or nearly a third, of the deaths occurred in public institutions. The deaths of infants corresponded with the number in the previous week, while those of elderly persons showed a further marked increase. The causes of 42, or more than 16 per cent., of the deaths registered during the week were not certified.

THE HIGH DEATH-RATE IN PRESTON.

A paper entitled "A Critical Inquiry into the Causes of the High Death-rate of Preston" was recently read by Dr. J. A. Rigby before the Medico-Ethical Society of that town. This subject, which is one of more than merely local interest, has recently attracted, as it undoubtedly should do, considerable interest in the town. Dr. Rigby appears to have convinced himself, on two grounds, that the true death-rate of Preston is considerably overstated in the Registrar-General's returns: in the first place, by a large under-estimate of the population; and, secondly, because, as he asserts, the high death-rate is to a large extent the natural result of the high birth-rate that prevails, and has long prevailed, in Preston. As regards the asserted under-estimate of the population of Preston, it may be pointed out that the Registrar-General's estimate of the population in the middle of this year, based upon the usual hypothesis that the rate of increase that prevailed between the last two censuses has since been maintained, is almost identical with the estimate based upon the rate of increase of inhabited houses in the borough between the middle of 1881 and the middle of 1885. It follows, therefore, that if the Registrar-General's estimate is very considerably below the actual number of the population, that the proportion of persons to a house must have largely increased since 1881. Moreover, the Registrar-General's estimate of population shows a very large decline in the birth-rate in Preston since 1881, which is scarcely consonant with the asserted recent exceptional increase of population by the immigration of 3000 dock labourers and their families, the natural effect of which would be to raise the birth-rate. We do not doubt the immigration of the dock labourers; but is it not very probable that they have merely supplied the place of other immigrants who would have been attracted to this manufacturing centre since 1881 but for the general commercial depression? In the face of these considerations, we cannot accept the assertion of a large under-estimate of the population of Preston. But that Dr. Rigby in his paper entirely ignores all that has been written and said during the last ten years upon the vexed question of the inter-relation of birth-rates and death-rates, it would appear almost necessary to apologise for asserting once more in these columns that the high birth-rate in Preston, far from explaining, only accentuates the high death-rate in that town as evidence of insanitary condition. It ought not to be necessary now, in criticising a "critical inquiry" into the causes of any high death-rate, to point out this generally exploded fallacy which has once more been asserted by Dr. Rigby. A high birth-rate in any population necessarily implies, in the first place, an exceptionally large proportion of young adults, who are liable to a low death-rate, and also implies a smaller proportion of old people, whose death-rate is high; moreover, although a high birth-rate does imply a large proportion of infants and young children, it should be borne in mind that the death-rate of children over four years of age falls below the mean age at all ages, and that the death-rate of children between the ages of seven and twenty years is lower than at any other period of life. On these accounts the age constitution of all populations having a high birth-rate is more favourable to the death-rate than is the age constitution of a population which has a low birth-rate. For instance, presuming identical death-rates at each age period in Brighton and Preston, the age constitution of the former town would produce a death-rate at all ages more than 1 per 1000 in excess of the death-rate in Preston, although, as is pointed out by Dr. Rigby, the birth-rate in 1885 was only 26·1 in Brighton, instead of 39·2, as in Preston. We hope, therefore, that those most interested in the sanitary condition of Preston will not be misled by Dr. Rigby's assertion of the over-statement of the death-rate into relaxing their efforts to arrive at the true explanation of the high rate of mortality in the town. We have seen no attempt to determine the death-rate of the town at different groups of ages, or the rates of mortality from the different classes of disease, which are both absolutely indispensable to determine the true import of a death-rate. Dr. Rigby does not attempt to controvert the existence of exceptionally high

Digitized by Google

infant mortality in Preston, but attributes it to excessive proportions of illegitimacy, to the exceptional prevalence of venereal disease, and to the effect of the large employment of married woman in factory labour.

Correspondence.

"Audi alteram partem."

THE EFFECT ON THE FEMORAL ARTERY OF LIGATURE AT THE APEX OF SCARPA'S TRIANGLE.

To the Editors of THE LANCET.

SIRS,—My best thanks are due to Mr. Savory for his courteous reply to my inquiry with reference to the abstract of his paper on this subject. Would you allow me space for a few lines on the very interesting surgical point which that paper treats? I am wise enough not to wish to enter into controversy with Mr. Savory, but if he will do me the kindness of correcting any error into which I may have fallen in treating of the condition of this artery after ligature, or any inadequacy in the expression of my ideas, I shall be very grateful.

I have always been taught, and have always taught, that after ligature of any artery on the old plan, where the vessel is divided by the ligature as it separates, a portion of the artery is obliterated, which in many cases reaches to the first considerable branch above and below. In some cases, however (as shown in the woodcut to which I referred in my last, on page 86 of the first, or page 90 of the fourth edition of my work on the "Principles and Practice of Surgery"), the extent of artery obliterated is much less. In the case of the superficial femoral, the tract of artery obliterated is sometimes as much as two inches (as in Porta's case, referred to and figured in the "System of Surgery," third edition, vol. iii., p. 52; and also described in "Gray's Anatomy," tenth edition, p. 412), sometimes, as in the case just mentioned, not more than a quarter of an inch. In one of Hunter's cases the whole artery was found obliterated, including the aneurysm, and this is the case which was probably in the mind of the writer whom Mr. Savory quotes. But I have always regarded this as exceptional, and probably caused in that case by the fact that a larger part of the vessel was exposed than is ever done now, and numerous ligatures perhaps used. In all ordinary circumstances, the blood returns into the portion of the artery below the ligature, and therefore when the artery is tied for aneurysm there are two arches of anastomosis: one, the higher, to carry the blood round the portion of the artery obliterated by the ligature; and the other, the lower, to carry the blood round the aneurysmal part of the artery, which, I believe, has been always found obliterated in cases cured by ligature, though not always in those cured by pressure. The principal importance of these facts lies in this: that from a very early period after the operation blood must be passing through the artery below the ligature into the aneurysm. I have always endeavoured to set out these facts in the plainest possible language in the various text-books in which I have treated of them—viz., in "Gray's Anatomy," "The System of Surgery," and my "Principles and Practice of Surgery," and I confess I was surprised to hear from so great an authority as Mr. Savory that no ordinary book stated that "the artery was pervious from the ligature to the aneurysm." Construing the words quoted strictly, no book does state this, for it is not true. Some part of the vessel must be obliterated below its point of division, or hæmorrhage would take place. But I submit that the works above referred to plainly state the facts as I have just put them, and I think they are in exact accordance with the gist of Mr. Savory's paper. If, however, my words as they stand in those books do not convey my meaning, I shall be glad to be corrected. Text-book writers are peculiarly liable to faults of expression due to condensation—"brevis esse laboro, obscurus fio."

I may add that the published descriptions are necessarily taken from the dissections of cases in which the artery has been divided by the ligature. In many of those where the vessel has not been divided (as I believe is now common), the portion of artery obliterated is probably very minute—n more than a mere diaphragm across the tube,—as shown i a case figured on page 93 of my "Principles and Practice c Surgery," fourth edition; and in such cases I myself believ it to be probable, though the fact has not yet been ascer tained, that the whole artery may again become pervious.

I am, Sirs, your obedient servant,

Jan. 1887. T. HOLMES.

ARTERIAL PRESSURE.

To the Editors of THE LANCET.

SIRS,—In endeavouring to master the mysteries of arteria pressure, I have arrived at the conclusion that our physio logists are scarcely consistent in themselves or with eacl other. The text-books I have studied are Foster's Physio logy and Brunton's Pharmacology, and should I have failec to comprehend the meaning of these writers, any explana tions that may be forthcoming may benefit many others, a well as myself.

In the first place it seems to me that we have to deal with two main factors: (1) the pressure of the blood on the arteries, and (2) the pressure of the arteries on the blood but it does not seem to me that either Foster or Bruntor has kept these two factors clearly in their mind's eye, and a most puzzling confusion is the result. Thus we are told by Brunton (page 226), that arterial tension and blood pressure is one and the same thing, and that the more tensely the arteries are stretched the greater is the pressure they exert on the blood they contain; whereas Foster states (page 203) that constriction of any vascular area increases the blood pressure there; so that we may apparently have increased pressure both with overstretched arteries and with contracted arteries. It would simplify the matter if we separate the terms arterial tension and blood pressure; or, better still, if we do away with the term arterial tension and substitute arterial pressure; making arterial pressure correspond to the pressure of the arteries on the blood; and blood pressure correspond to the pressure of the blood on the arteries. Bearing this distinction in view, it is evident that the more blood there is in the arteries the more the arteries will be stretched by the pressure of the blood on them; here, it would be said, the blood pressure is high. On the other hand, were the quantity of blood in the arteries not increased but the arteries constricted, then would the arterial pressure be high. It is also evident that the manometer will not distinguish between blood pressure and arterial pressure, but will simply register the combined pressure—the action and the reaction of these two factors. Bearing in mind the separate action of the two factors mentioned, it is easy to understand the statement of Foster that moderate bleeding does not reduce blood pressure, for evidently the pressure is maintained by the arteries contracting on the diminished volume of blood in them; but this fact is not in accordance with Brunton's statement that arterial tension is synonymous with blood pressure, for here we get a similar pressure with contracted arteries. To my mind, it is a most unfortunate and confusing statement to make *tonos* and stretching one and the same thing; nor is there any proof given that the more the arteries are stretched the more pressure they exert on the blood in them. The more the blood stretches the arteries the greater is the pressure of the blood *on them;* but it is doubtful if an over-stretched artery exerts relatively higher pressure than one less stretched. On the contrary, Foster states that the tone of any vascular area may be augmented by constriction—that is, that the constriction increases the pressure.

Then, again, the statements in Foster (page 185) relative to the effects of constriction and dilatation of vascular areas, are, to my mind, far from being clear, and scarcely in accordance with his statements (page 207) that throwing more blood into the arteries does not increase the arterial pressure, nor bleeding directly diminish it; because if A (being a vascular area) be constricted, the effect of this constriction, we are told, is to increase the pressure in the remaining portion of the arterial system. But surely the effect of this constriction in A must be similar to adding blood to the circulation, which, we are told, does not raise the pressure. If, on the other hand, A be dilated, the remaining portion of the arterial system has its pressure lowered; but the effect of this dilatation in A on the remaining portion must be

Digitized by Google

similar to bleeding, which, we are told, does not reduce pressure. Then we may get the following associations on combinations—namely, increased pressure along with an increased flow of blood into the veins, and increased pressure with a diminished flow; diminished pressure with increased flow, and diminished pressure with a diminished flow of blood into the veins. These combinations are very puzzling until the two factors are separated, when they become more easy to understand. Thus, increased pressure, the result of an increased quantity of blood, is accompanied by an increased flow into the veins; but increased pressure, the result of contraction of the artries, is accompanied by a diminished flow, and diminished pressure, the result of the arteries pressing less on the blood (i.e., dilatation) is accompanied by an increased flow; but a diminished pressure the result of less blood is accompanied by a diminished flow. Without this distinction it is somewhat difficult to see what necessary connexion there is between pressure and flow, but with this distinction it is apparent. The last point I will discuss is the effect of section of the renal nerves on pressure in the vessels of the renal glomeruli; this section causes the renal arteries to dilate, and both Foster and Brunton state that this dilatation leads to an increased pressure in the vessels of the glomeruli, and Foster further states that this occurs, although the pressure in the renal arteries is lowered. This is very difficult to follow, and where the increased pressure comes from I cannot conceive. It cannot come from the renal arteries, whose *tonos* or tension is gone; it cannot come from peripheral resistance, for that is gone with the section of the nerves; and peripheral resistance being gone, pressure from behind cannot cause it, as the renal arteries, with lowered pressure, intervenes. In my opinion section of the renal nerves does not cause increased pressure in the vessels of the glomeruli, although more blood passes through them.

Space forbids me discussing other interesting problems, and, in conclusion, if my criticisms of such eminent authorities as Foster and Brunton are radically wrong, I can only express my sorrow for it, and spend two or three months more in trying to overcome the intricacies of vascular pressure.

I remain, Sirs, your obedient servant,

Dartmouth, Nov. 23rd, 1886. W. NICHOLSON, M.D.

SUPPURATION IN THE APPENDIX VERMIFORMIS.

To the Editors of THE LANCET.

SIRS,—An instance of suppuration in the vermiform appendage of the cæcum causing enteritis and peritonitis is so rare that I hope you may deem it worthy of record in the pages of THE LANCET. A man aged forty-two, occupying the position of an in-door servant as hall-porter, was seized with severe pain in the abdomen, vomiting, and such prostration that he was scarcely able to stand. On seeing him the following morning, I found him with tenderness spread all over the abdomen and considerable tympanites. The tenderness was more marked on the right half of the abdomen than on the left, and there was one spot, about an inch to the right of the umbilicus, where the pain was intensified; here, too, there was some slight bulging of the abdominal walls, but no additional hardness. The pulse was 80, and the temperature normal. An enema was given of gruel and castor oil, which was expelled free from fæcal matter; a hot linseed poultice was placed all over the abdomen, and changed every four hours; a grain of extract of opium was administered every six hours; simple farinaceous nutriment was given in small quantities, but was ultimately all rejected. On the third day the pulse remained at 80, and the temperature continued normal; the abdomen was less tympanitic, and less tender; the vomiting continued, and there was a total inability to retain nourishment by the stomach. Nutrient enemas of an extract of beef, with port wine, were now administered every eight hours, and retained; and the opium was continued, though less frequently. On the fourth day the pulse had risen a little, but the temperature remained normal; the bowels acted freely, the excretion consisting of yeast-like semi-solid material; the tympanites and tenderness both lessened, and the bulging to the right of the umbilicus had disappeared; but the skin had become bedewed with a cold clammy perspiration, and there was great prostration. On the fifth day the abdominal symptoms had somewhat abated; the bowels acted again, but violent retching continued, and the vomit had become distinctly stercoraceous; the pulse rose to over 100, and the temperature to 101°; the nutrient enemas and opium were continued; but the cold and clammy perspiration did not abate. On the sixth day the abdominal symptoms were less severe; the bowels acted again, with evident relief to the abdomen; but the retching continued, and the vomited matter was still stercoraceous. The chief distress was now referred to the epigastrium, apparently caused by the violent retching. Cotton-wool was substituted for the poultice; the nutrient enemas and opium were continued. On the evening of the sixth day symptoms of collapse set in, and death ensued in the night.

An examination of the abdominal cavity was made twenty-four hours after death; there was subacute inflammation of the peritoneum and of the intestines, increasing in degree towards the cæcum, but was more marked in the small than in the large intestines. The discolouration was most marked around the vermiform appendix. The appendix was very discoloured at its base, as if it had been constricted, but no band could be detected. The body of the appendix was distended, which, on being laid open, was found to contain a small quantity of sanguineous pus, but no other foreign material could be detected. A gooseberry-pip, a cherry-stone, a mustard-seed, the small pips of a fig, and a piece of hard fæcal matter have been known to intrude into the vermiform appendix, and set up fatal enteritis and peritonitis, but I cannot find any case of suppuration recorded. As the appendix exists only in human beings, in the ourang-outang, and in the wombat, but, as far as is known, in no other animal, its presence is probably not essential to life. The question naturally arises, would removal by operative interference afford relief in cases similar to the one recorded when the symptoms pointed sufficiently to the seat of mischief?

I am, Sirs, yours obediently,

Wokingham, Jan. 1887. J. G. BARFORD.

THE GENERAL PRACTITIONERS OF ENGLAND: THEIR COLLEGIATE RIGHTS AND DUTIES.

To the Editors of THE LANCET.

SIRS,—The announcement which you have made of the proceedings about to be taken by the College of Surgeons and the College of Physicians of England respectively indicate an important crisis in the affairs of the profession. It is one which avowedly concerns the general practitioners of England above all others. The steps about to be taken by the Colleges will affect for good or for evil the position, the status, the rights, and the privileges of the general practitioners now and in the future. Avowedly, and as we are well disposed to believe, in fact, many of the changes about to be introduced will give increased facilities for graduation in London, and will thus bring the title of M.D. within the reach of London students on reasonable terms. This is much to be desired. On the other hand, corporations continue to treat the great mass of the profession as though they were persons without any right to a voice in their own affairs and without any capacity for controlling them. The indignity with which the College of Surgeons treats its Members and the calm contempt with which the College of Physicians utterly ignores its Members and Licentiates are likely to be perpetuated, so far as can be gathered from their present proceedings, in the conditions under which they will endeavour to frame the new Charters which they are about to send from the Privy Council. It will be in the power of the general practitioners of England, Members of the College of Surgeons, and Licentiates of the College of Physicians to determine whether they choose to be thus completely ignored in the medical republic of the future. We use here incidentally and involuntarily a phrase common enough in the mouths of all, but which is in itself under existing circumstances a bitter satire. We talk of the republic of letters and of the republic of medicine, because it is a self-evident axiom that the educated members of a profession stand for all the great purposes of fraternity, of progress, and of self-government upon an equal basis; but, in point of fact, the existing government of the profession by the London corporations is an oligarchy, consolidated by self-assertion, and based upon the survival of mediæval anachronisms.

Digitized by Google

The College of Surgeons and the College of Physicians are alike mediæval guilds, which bring to the administration of modern affairs a framework of effete guilds of which the *raison d'être* has long ceased to exist. If anyone were now seriously to propose, in framing a government for the profession of medicine, that the whole power should be concentrated in the hands of a self-nominated and self-elected clique of hospital surgeons and physicians constituting less than 5 per cent. of the whole body, that the whole funds, buildings, powers, and accumulated surplus of fees should be vested in their hands, such a scheme would stand self-condemned. It has no basis in reason or justice or any similitude in any constitution framed in this century. This, however, is what the Colleges of Surgeons and Physicians are now striving to create anew by the favour of the Crown in the new Charters for which they are asking. Sir Henry Pitman evidently saw at once with his veteran acuteness the weakness and the strength of the renewed effort of despotism which the College of Physicians is making, when he jubilantly reminded the comitia that they would not have to go to Parliament for their Charter, but that they would be able to obtain it by influence with the Crown. No doubt some of the most eminent of the present governors of the two Colleges are very near the Crown, they are close to the steps of the Throne, and they are well acquainted with the avenues and staircases of the Privy Council. What can be said, however, of a scheme with which the promoters fear to face Parliament? In fact, this fear is the strength of, and should give courage to, the practitioners of England. Nor need it even be feared that the Privy Council will allow itself to be approached exclusively by the Councils of the Corporations, and will be deaf to the representations of the many thousands who constitute the commonalty of both Colleges, and on whose support, and by whose existence, these Corporations live, move, and have their being. The Association of General Practitioners will claim for that order, to which the State is indebted for its medical work in all the great towns, throughout the rural districts, in the Army, in the Navy, and in the Poor-law service, that they shall be represented in the constitution of the Colleges and of the new University. They will claim that their voice shall be heard, and that their influence shall be felt, and, unless these just concessions be made, they will ask that no new Charters or additional privileges be granted until a Royal Commission has been appointed to inquire into the constitution of the Colleges, into their relations to the whole profession, and into the wishes and rights of the profession in the constitution of the new University. To support this scheme, we invite those of your readers who agree with us to shake off the apathy which long years of submission to the Councils have bred, and to claim for themselves a universal interest and an individual power in the government of the body to which they belong. We ask those who agree with us to favour us by a post-card. We invite your support as having always been the advocates of the rights of the general practitioners. The traditions of THE LANCET, to which you have with justice lately proudly referred, are on the side of the profession at large, and opposed to the sole possession of exclusive privileges by small bodies of self-elected persons. We confidently count upon your aid in this great matter.—We are, Sirs, yours faithfully,

H. WALTER VERDON, 410, Brixton-road, S.W. } Hon. Secs., Assoc. Gen. Pract.
W. GIBSON BOTT, 414, Clapham-road, S.W. }

Jan., 1887.

"DEGREES FOR LONDON MEDICAL STUDENTS."

To the Editors of THE LANCET.

SIRS,—It must be a matter of great gratification to all those who take an interest in the matter that the Royal College of Physicians of London and the Royal College of Surgeons of England have now finally settled that it is "desirable and practicable to grant degrees in medicine and surgery to persons who have passed the Conjoint Examination of the two Colleges." Yet, I am afraid the whole object will be defeated if Sir William Gull's suggestion be adopted—"That a further examination in Clinical Medicine and Surgery be instituted for the M.D. and M.S. degrees respectively." Why cut up the degree thus, after the fashion of the London University, for this would be doing the very thing that is not wanted? The London student requires that he can obtain the degree of M.D. on a par with the Scotch and Provincial Universities. It is already acknowledged that the Conjoint Examination is equal to that for their degree, and in their case the only thing required in proceeding to the M.D. degree after the M.B. is the writing and reading of a thesis. Should Sir William Gull's suggestion be adopted, the new University will be thereby defeating its primary object. I am interested to know upon what terms those holding the two qualifications during past years would obtain the new degree? Having obtained the double qualification, would the University confer the degree upon them? if not, unfairness might be complained of.

I am, Sirs, yours faithfully,

R. W. SUTTON BARRACLOUGH, M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng.

Dulwich-road, Herne-hill, S.E., Jan. 3rd, 1887.

THE FILARIA SANGUINIS HOMINIS.

To the Editors of THE LANCET.

SIRS,—It may interest many to know that I have at the present time under my care at the London Hospital a patient suffering from chyluria, whose blood and urine contain living embryos of the filaria sanguinis hominis. The number of embryos found in the blood are not so numerous in this as in a previous case under my care at the hospital. The "periodicity of filarial migration," however, is equally characteristic, the embryo filariæ swarming into the blood at night and disappearing from the general circulation during the day-time. The patient, who contracted the disease in India, was sent to me by Dr. Clay of Plymouth. I propose to exhibit "living specimens" of the embryo filaria sanguinis hominis at the Clinical Society on Jan. 14th.

I am, Sirs, faithfully yours,

Finsbury-square, Jan. 4th, 1887. STEPHEN MACKENZIE.

THE BATH WATERS AND ARSENIOUS ACID.

To the Editors of THE LANCET.

SIRS,—The marvellous efficacy of a course of Bath waters in anæmia, nodular rheumatism, and chronic skin disease has long been an established fact; but to what special therapeutic agency this efficacy was due has, so far at least as written evidence proves, been hitherto inadequately accounted for. Indeed, had not the generally accepted analyses of these waters utterly failed in my mind to account for their undisputed curative action in the diseases referred to, the experiments leading to the demonstration of the fact hereafter detailed would never have been initiated by me, and the publication of what, I trust, my professional brethren may consider a useful contribution to thermal-water therapeutics might have been reserved to another. In endeavouring to account for the apparent specific action of the Bath waters, I mentally passed in review those therapeutical agents which, while exercising distinct action in the diseases referred to, might at the same time be reasonably expected to be held in solution in natural mineral waters. Arsenic in some form took immediate prominence, and the fact which I subsequently ascertained, that its presence would account for the tardy precipitation of the iron after the escape of the excess of CO_2[1]—a peculiarity in the behaviour of these waters, otherwise inexplicable—tended to confirm me in the opinion that in spite of no allusion to the presence of arsenic in the region of analyses of the Bath waters, it must be there. I immediately sought the analytical aid of my friend, Mr. Gatehouse, the well-known and much-respected public analyst of Bath, and after very careful and reliable tests, the particulars of which I shall be glad to furnish on application, we have demonstrated the presence of arsenic in minute quantities in the Bath waters; thus I hope rescuing one more of nature's own cures from the Cimerian darkness of empiricism.

I am, Sirs, yours truly,

Bath, Jan. 2nd, 1887. T. P. LOWE, M.R.C.S., L.R.C.P.ED.

[1] A most important fact when transmission of the waters for use at a distance is considered. Precipitation of the iron does not take place for several hours after the escape of CO_2, which is of course contrary to the behaviour of carbonate of iron held in solution by excess of CO_2, which falls to the bottom almost directly the CO_2 has escaped.

LIVERPOOL.

(From our own Correspondent.)

HOSPITAL SUNDAY.

NEXT Sunday is the seventeenth anniversary of Hospital Sunday in Liverpool, and the result will be awaited with considerable interest. It is hoped that additional evidence will be afforded as to the real improvement in trade and commerce by the increased amounts deposited in the collecting plates. Efforts have been made to bring about a change in the date of Hospital Sunday from the second Sunday in the year to a Sunday in May. Much is to be said both for and against the change, and the amount collected next Sunday will no doubt guide those who will have to decide whether the change shall be made or the date remain as at present. Great efforts are being made to ensure the co-operation of all clergy and ministers this year, there having been in past years several who have failed to make a collection for the medical charities either on Hospital Sunday or on any other Sunday. It is only just that every congregation should have the opportunity afforded them of giving substantial proof of their appreciation of the medical charities.

THE CHRISTMAS SEASON AND THE POOR.

In Liverpool, as elsewhere, Christmas was accompanied with seasonable—that is to say, very severe—weather. It is very pleasing to notice the liberality with which the public responded to the appeals made to them for aid in providing Christmas breakfasts as well as Christmas dinners. Thousands of hungry men, women, and children have been fed with substantial food, as well as supplied with coals—a most acceptable gift.

THE ROYAL INFIRMARY.

For many years past the present buildings of the Royal Infirmary have been found to be wholly inadequate for their purpose, and recently a large sum was raised by public subscription towards erecting a new one. A building committee was appointed, and the greatest care has been taken to ensure that the new infirmary shall comprise every real modern improvement. Satisfactory progress has been made with the plans, which are now nearly complete. Contracts, it is expected, will shortly be entered into, and the work commenced early in the spring.

THE ROYAL SOUTHERN HOSPITAL.

On Tuesday night a gigantic Christmas tree covered with articles of general usefulness—viz., petticoats, shirts, socks, warm muffs, caps, and flannels of all descriptions—was stripped of all its ornaments, which were distributed to the patients throughout the house and to everybody within the hospital without distinction. Accompanying this was a musical entertainment, with songs. Mrs. Geo. H. Horsfall, the wife of the chairman of the hospital, attended and presented the gifts with a few kindly words. Not the least gratifying circumstance was that some of the patients, hearing of the coming event, voluntarily knitted an embroidered fancy work, which they desired should be given to the physician or surgeon under whose care they were—a delicate attention which the latter were not slow to appreciate. Mr. G. W. Moss has offered to present to the hospital an ambulance, complete and free of cost. The offer has been accepted, it being understood that the management of the ambulance, which will be about £300 a year, shall not encroach on the general funds of the institution.

THE RESULTS TO PLYMOUTH AND DEVONPORT OF THE REPEAL OF THE CONTAGIOUS DISEASES ACTS.

Before the Royal Commission, which sat in 1870 to inquire into the Contagious Diseases Acts, a witness from Devonport expressed an opinion that the total repeal of these Acts would be "disastrous"; and a memorial, which was signed by magistrates, clergy, medical practitioners, and others in the boroughs of Plymouth and Devonport and township of Stonehouse, was forwarded in 1882 to the Commissioners for executing the office of the Lord High Admiral of the United Kingdom. Its concluding paragraph is: "We cannot too strongly express our opinion that the repeal of these Acts would be a great misfortune to this district, and to any other community where they exist at present." How thoroughly these predictions have been fulfilled is shown by what is stated in a contemporary of the 1st inst., under the heading Plymouth: "To-day the whole of the patients in the lock wards of the Royal Albert Hospital, Devonport, have been discharged into the streets uncured, and the wards are closed. This is in pursuance of the operation of the Act for the Repeal of the Contagious Diseases Acts passed last session, and no ameliorative substitute of any kind has been provided. Prominent agitators against the Acts deplore this result, the disastrous effects of which have become lamentably conspicuous; and almost every public body here and in Devonport has expressed an opinion strongly against the present condition of affairs." Mr. Stansfeld, speaking in the House of Commons in 1876, expressed his conviction that if the Acts were repealed voluntary lock hospitals would be established and supported wherever they were required. The Acts have now been repealed for some months, the Royal Albert Hospital is closed, and we shall very likely soon hear of the closing of all the Government lock hospitals in Portsmouth, Chatham, Colchester, Cork, Kildare, and the Government wards of the London Lock Hospital. The opponents of the Acts succeeded in raising thousands of pounds every year towards their repeal, but nothing whatever has been done towards providing lock hospitals for the women who were cared for by the Government, and who are now "literally out in the cold." That the Acts will have to be re-enacted goes without saying, and even before this can be brought about some aid will probably be afforded by the State to enable the above-named hospitals to be kept open for such patients as may apply voluntarily. Meanwhile the public will have leisure to observe the unscrupulous nature of the opposition to these Acts. Those who raised and persisted in it have incurred a fearful responsibility, for which they will most certainly have to answer. They have sown the wind, and must reap the whirlwind. The Acts are repealed, the Government hospitals are closed, the unfortunate women who were in them are deprived not only of all means of cure but also of reclamation. Venereal diseases have enormously increased in the army and navy, and—although this cannot be shown by statistics—among the civil population. And as a set off against all these evils what good has been accomplished?—simply nothing.

COLDS CAUGHT AT FUNERALS.

It is always an ungracious task to write in disparaging terms of any good old custom, whatever inconveniences it may involve. This is enhanced when the custom is founded upon good motives; but, as guardians of the public health, it becomes necessary to speak plainly of the custom of standing bareheaded at funerals round the grave, while no small portion of the burial service is being read. Some clergymen curtail this by reading in the church or chapel all except what is known as the prayer of committal to the ground. But the truth is that the average Englishman is incapable of standing bareheaded in the open air, even for the shortest interval, without incurring a serious risk. It is to the colds caught in such weather as we are now experiencing that I would wish to call serious attention. Even country doctors, whose constitutions have become well seasoned to rides and drives in all weathers, feel it trying to attend funerals on this account. The remedy is simple and obvious. There is all the difference in the world between the slightest covering to the head and no covering at all, more especially to those who are partly or entirely bald. Many clergymen and chaplains of cemeteries have adopted the sensible practice of wearing skull-caps of black velvet or silk, and laymen would soon follow the example had they some definite authority to do so. But till then respect for the dead and reverence to the solemn words being read deter them from adopting a precaution which might save many a severe cold, if not a more serious illness. Medical attendants can surely speak authoritatively upon this point, for health is much too precious to be sacrificed either to reverence or respect for the dead. But it is desirable to have ecclesiastical authority as well, and I would respectfully suggest to the archbishops, bishops, and clergy generally, that a few words from them would inspire the laity with more confidence, and save many a mourner, pall-bearer, or other attendant at funerals, from what are mildly designated colds, but which in not a few instances have passed on to even fatal illnesses.

Liverpool, Jan. 1887.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE CARRIAGE TAX AND DISINFECTANTS.

A CURIOUS case bearing on the carriage tax was tried and decided at the North Shields Police-court last week. An inland revenue officer summoned Mr. Harbottle, sanitary inspector, Tynemouth, for using two carriages while he held a licence for one only. Mr. Harbottle showed that in his public capacity as sanitary inspector he was obliged to use a conveyance for the purpose of carrying disinfectants to the various townships in the district. On a certain occasion the ordinary conveyance broke down, and, as he had to go to the railway station for some disinfectants, he was compelled to use a four-wheeled vehicle, of which the inland revenue officer now complained, and which he had been absolutely compelled to do for the public safety. The magistrates held that there was no evidence on the part of Mr. Harbottle to act contrary to the law, and dismissed the case. The carriage tax is very unpopular in the north, and prosecutions of this nature are not calculated to raise it in public esteem.

A VACCINATION CASE.

An inquest was held last week on a child aged three years, in the Byker district of Newcastle. The mother said that when it was three months old it was vaccinated by the public officer. Afterwards an eruption broke out on its head, and finally it suffered from a discharge from the ears, for which it was duly attended by a medical man, and also by the dispensary visiting assistant. There was no medical evidence adduced at the inquest. The jury returned a verdict to the effect that "the deceased died from natural causes, apparently accelerated by foul vaccination." It is to be regretted there is so often no medical evidence called in these cases, as these verdicts have a mischievous tendency when published, and may some day be the indirect cause of great loss of life, as creating a prejudice against the only known preventive of small-pox.

TYPHOID AND WATER HYDRANTS.

Dr. H. Ward, medical officer of Blyth and Tynemouth rural sanitary districts, points out a cause of typhoid which he believes has been hitherto overlooked in connexion with water hydrants. He alludes to the apparatus known as the self-acting ball hydrant, which he believes is defective when applied to under-ground pipes. The self-acting ball is the simplest of all hydrants; it consists of a ball of gutta-percha placed within a pipe projecting within the main. When the water is turned on, it is forced up against the aperture, which is smaller than the ball, and so prevents the water from escaping; but as soon as the water is turned off at the main, the ball falls and allows air to pass into the pipes, this being the object of the invention. Dr. Ward states that when the hydrants are placed above ground the apparatus is admirable, but the effect is totally different when they are sunk under ground. The hydrants, he says, in his district are sunk under the ground in the middle and towards the end of back streets, at a distance of about seventy yards apart, and are covered over by iron lids loose in an iron socket. They are also placed in many instances close to an ashpit door, so that when the scavengers are at work the hydrants are frequently covered by the contents of the ashpit, the liquid filth of which must frequently drain into and accumulate in the hydrant box, and contaminate the water. That such is the case Dr. Ward is satisfied from close observation, and points out that, in connexion with a recent epidemic of typhoid, the people living in close proximity to the hydrants suffered most, the disease being more virulent and fatal than in other localities in the district. Dr. Ward's remarks apply to the Cowper sanitary district, and are of much importance in connexion with water-supply and sanitation.

Newcastle-on-Tyne, Jan. 4th.

THE CLIMATE OF THE LAKE DISTRICT.—A clergyman residing at Keswick, writing to a daily contemporary, states that on the day (Sunday, the 26th ult.) when the midland district, and, indeed, almost the whole of England, was suffering from all the horrors of an arctic winter, the residents of the English Lake district were enjoying a day of exceptional calmness and genial temperature.

DUBLIN.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

ON the 30th ult. an election for a member of the Senate took place, and a statement in THE LANCET of last week, in which I remarked that most probably Professor O'Sullivan would be successful, has turned out correct. The voting was as follows: Professor O'Sullivan, 316; Dr. McMordie, 231; Mr. O'Connor, M.P., 166. The majority Professor O'Sullivan obtained was far beyond the expectation of his most sanguine supporter. It is stated that the following resolution, which was passed at a meeting of the executive committee, was sent to the graduates previous to the election by "The Graduates' Reform Association of the Royal University of Ireland": "That, inasmuch as it has come to our knowledge that a considerable number of electors of the University pledged their support to Dr. O'Sullivan while unaware of the candidature of Mr. T. P. O'Connor, M.A., M.P., and inasmuch as such pledges, given under a misapprehension of the facts, cannot be binding, the committee trust that the electors from whom promises to support Dr. O'Sullivan were obtained under a misapprehension and before they were aware that Mr. O'Connor was in the field, will not consider themselves bound thereby, and will use their influence to secure Mr. O'Connor's election." At the meeting of Convocation a resolution was adopted, by a narrow majority, to the effect that a special committee should be appointed to frame new standing orders of Convocation and discharge the duties hitherto assigned to the Annual Committee. Prof. Pye's motion (see p. 49), in reference to medical degrees, was amended by calling the attention of the Senate to the matter, and was then adopted. The following resolution was also passed:—"That Convocation is of opinion that hitherto honorary degrees have been conferred much too liberally, and that the Senate be requested henceforth to examine carefully the special claims of all upon whom it is about to confer such honours."

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The question of the College conferring a diploma in Sanitary Science has, I believe, been under the consideration of the Council, and a committee has been appointed to confer as to the necessary details. As the College of Physicians, the University of Dublin, and the Royal University of Ireland grant these diplomas, there appears no valid reason why the College of Surgeons should not do likewise. If the Council determine to grant the diploma, four examiners will be appointed to examine candidates in the required subjects of examination.

THE CROWN SEAT FOR IRELAND IN THE GENERAL MEDICAL COUNCIL.

I am informed that the Government have appointed Mr. E. H. Bennett, Professor of Surgery in the University of Dublin and an ex-President of the Royal College of Surgeons in Ireland, to be a representative on the General Medical Council in the room of the late Dr. Robert Dyer Lyons. Mr. Bennett has also been appointed a Medical Visitor in Lunacy under the Court of Chancery.

REPORTS AND PAPERS RELATING TO PUBLIC HEALTH.

Sir Charles Cameron, medical officer of health for Dublin, has recently published a volume consisting of nearly five hundred pages, whose contents are chiefly reprints of papers contributed at various periods to the *Dublin Journal of Medical Science*. It would be impossible to refer to the various articles, all on subjects of considerable interest to the community, which Sir Charles Cameron has collected into a single volume; but I may mention particularly the following as examples: "Cremation or Burial?" "Insanitary Condition of Canal Boats"; "Contagion and Bacteria"; "How Typhoid is Spread"; "Etiology of Diphtheria"; "Colour Blindness"; "Sewage in Oysters"; "Lead Poisoning among Workmen"; "The Germ Theory of Phthisis"; "Hospital Construction and Management," &c. Sir C. Cameron has a facile pen, his style is remarkably good, and his communications are eagerly read by all classes of the community, both lay and professional. Considering the various offices and appointments the author of these reports holds, and the duties of which he discharges in a thoroughly efficient manner, it is a mystery to many how he can find time for

Digitized by Google

the enormous amount of literary work he accomplishes. Last year he finished his "History of the College of Surgeons," a work which was reviewed in THE LANCET and other medical journals, and which was on all sides spoken of in the highest terms.

THE RICHMOND HOSPITAL, DUBLIN.

The appointment of a physician to this Hospital, in the room of the late Dr. Lyons, will take place on the 13th inst. I was under the impression that the physicians were paid by the Government at the rate of £100 per annum, but if so a change has taken place in the arrangements, as the gentleman who succeeds Dr. Lyons will not receive any salary. Whether he may be allowed a share of the students' fees is a matter of which I am ignorant; but as one of the medical staff he certainly would be entitled to it.

NATIONAL EYE AND EAR INFIRMARY, DUBLIN.

A children's amateur theatrical entertainment, in aid of the funds of this institution, will take place on the 6th inst. The performance will be the "Sleeping Beauty," and the various parts will be filled by juveniles between the ages of four and thirteen years.

Samuel Connor, M.D., of Newry, has been placed on the Commission of the Peace for the county of Down.

Dublin, Jan. 4th.

BELFAST.

(From our own Correspondent.)

CHRISTMAS AT THE HOSPITALS.

THE inmates of the various hospitals in town enjoyed a very pleasant Christmas Day, thanks to the exertions of the ladies and gentlemen who assembled at these local institutions, and who used every effort to secure to the patients some of the comforts of the season. At the Royal Hospital the Board of Management and the resident staff paid every attention to the patients, while at the Hospital for Sick Children and at the Ulster Hospital the wards were most beautifully decorated, and in each Christmas-trees, covered with every form and variety of toy suitable to the age and sex of the little patients, occupied prominent positions. At the Throne Hospital, the Asylum, and the Union Workhouse the inmates were treated most sumptuously.

BELFAST DISPENSARY COMMITTEE.

At a meeting of this committee held on Monday, it appears from the reports handed in that the health of Belfast is in a satisfactory condition. There have been a large number of chest cases owing to the intense cold and damp weather, and some cases of scarlatina and enteric fever have occurred in one of the subdistricts. It was stated that there has been a slight decrease in the cost of maintaining the various Belfast dispensaries during the past year. It was agreed to grant Dr. Mehany, one of the apothecaries, an increase of £5 per annum, subject to the approval of the Local Government Board.

ARMAGH LUNATIC ASYLUM.

I learn that Dr. Graham, who for nearly three years has been assistant medical officer at the Belfast District Lunatic Asylum, where he discharged his duties to the entire satisfaction of the governors, has been appointed to the important post of resident medical superintendent of the Armagh Lunatic Asylum. Owing to Dr. Graham's promotion there is a vacant post, and for it I hear that Dr. Graham (a brother of the former assistant), Dr. Collier, and Dr. Thompson are candidates.

Belfast, January 4th.

PARIS.

(From our own Correspondent.)

M. PETER ON THE INTENSIVE METHOD.

A GRAND discussion has taken place at the Academy on a case of hydrophobia communicated by M. Peter. The subject of the observation had been bitten six weeks before, and had undergone the intensive treatment within forty-eight hours. Four days before his death he was seized with pains, which radiated, not from the cicatrix of the bite, but from the points where the inoculations had been practised. He then fell into a state of stupor and prostration, and died in a paralytic condition, foaming at the mouth. M. Dujardin-Beaumetz contested the value of the observation on two grounds: in the first place, because the existence of rabies had not been confirmed by experimental transmission to the animals by inoculation with diseased medulla; and, secondly, because most of the symptoms usually seen, more particularly the spitting, had not been mentioned by M. Peter, and because the paralytic form of rabies, of which the patient was said to have died, was extremely exceptional in man. M. Verneuil begged the Academy not to be influenced by communications such as that of M. Peter. Let M. Pasteur's work be disproved, if such is its fate, said the speaker, by scientific argument, and not by gossiping tales. M. Peter, in reply, remarked that no one could contest the fact that the man was dead. That he had been bitten and had undergone the intensive treatment were equally sure. These circumstances formed a "natural series," and had the inoculations not been performed, no one would have doubted that the case was one of rabies. M. Dujardin-Beaumetz had pointed out that the paralytic form of rabies—that which follows, as a rule, laboratory inoculations—is excessively rare after a dog-bite. But, said M. Peter, this is a point of great importance. The man had been subjected to inoculations, and had died with symptoms of rabies such as are not usually met with in hydrophobia, but which are those that do occur in experimental rabies, and that have already been observed in England in those dying of the disease after Pasteur's treatment.

PANEGYRIC OF FLOURENS.

At the annual meeting of the Academy of Sciences it is customary for one of the perpetual secretaries to pronounce the panegyric of an eminent predecessor. This year the duty devolved upon M. Vulpian, who selected as his subject the life and scientific work of Flourens. The *éloge* is an analytical study of the most remarkable works left by the illustrious perpetual secretary, whose place M. Vulpian now occupies, and the fullest justice is done to his memory as a physiologist—a title with which it was Flourens' desire to pass down to posterity. Allusions were made to his opposition to the doctrine of cerebral localisation when first proposed by Gall, and his adverse "Examination of the book on the Origin of Species"—a work which justified, said M. Vulpian, the bitter criticisms bestowed upon it by Darwin. M. Vulpian seems to me less remarkable for impartiality when he assigns to Flourens the credit of the discovery of the anæsthetic properties of chloroform on the strength of his experiments with it in the physiological laboratory. The discovery of the value of chloroform in medicine undoubtedly belongs to Sir James Y. Simpson, and is too well established to admit of any such posthumous claims.

ELECTROLYSIS.

The introduction of a medicinal agent into the body by means of electrolysis is a possibility that has been entertained by competent authorities, amongst whom I may mention MM. Onimus, Courserant, and Spellmann of Nancy. I may confess, then, that upon reading the annotation in THE LANCET of Dec. 18th, "On a New Method of Employing Electricity in Neuralgia," in which it is stated that Dr. Adamkiewicz had found the passage of galvanic current through a cathode saturated with chloroform exceedingly effective in various kinds of neuralgia, I remembered that a communication had been made some time back at the Academy of Sciences on the Introduction of Medicines through the Skin by Electrolysis, and it occurred to me that the efficacy of the Dr. Adamkiewicz treatment might be due to the same cause. In the communication I allude to Dr. Brondel of Algiers stated that when certain salts were placed upon the skin under the cathode, the passage of the current producing their decomposition caused the acid element, or rather the metalloid playing the part of an acid, to dialyse through the tissues to the anode, where its presence was easily demonstrated by ordinary chemical tests. By this process he had been able to apply iodine and bromine to any internal organ selected, and had iodised the lung, the uterus, and the joints, and "brominised" the brain, &c. In proof of his assertions, M. Brondel adduced the following facts:—(1) The patients, being submitted to the electrical introduction of iodine, taste it; (2) its action is shown by the cures following the treatment; (3) when the iodine salt (KI) is placed under the cathode the starch at the positive electrode quickly becomes blue from the passage of the iodine. These experi-

Digitized by Google

ments were repeated at the Cochin Hospital by M. Dujardin-Beaumetz, whose therapeutic experience led him to set aside M. Brondel's first two reasons as susceptible of fallacious deductions, *post hoc ergo propter hoc* being but a poor argument, especially in medicine. Taking for granted the exactitude of M. Onimus's conclusions with respect to animal electrolysis, and admitting *a priori* the possibility of the penetration of chemical substances into the body by this means, M. Dujardin-Beaumetz wished to ascertain if one element of a salt decomposed under one electrode could really pass as far as the opposite pole, and, if so, what were the conditions of success? The manipulations were made by MM. Brondel and Dujardin-Beaumetz, and everything turned out as was expected. But when the electrodes were applied by other persons, the iodine refused to pass and the starch at the positive pole would not turn blue. Had this perplexing result occurred at the Paris Société de Biologie in the month of December, 1886, I entertain no doubt whatever as to the explanation that would have been afforded. We should have had an interesting discussion upon "the effects of suggestion upon inorganic matter," and the most curious, complicated, and unexpected discoveries would have been made. As it was, the experiments were repeated with renewed care again and again, until it became evident that the blue colouration was caused by decomposition at the positive pole itself whenever a small quantity of iodide was accidentally deposited there by insufficient care in manipulation. When the two electrodes were held by different persons, and perfectly free from iodide, no discolouration of the starch took place. The whole question has been studied afresh by M. G. Bardet, and, after repeated and careful experimentation, he concludes that dielectrolysis through organic tissues is impossible.

THE REMOVAL OF THE OVARIES IN HYSTERIA.

After meeting with considerable opposition here when first made known, Battey's operation is gradually coming into favour, and though we cannot as yet compete in surgical activity with Liverpool, a number of speakers were able to give their experience of the operation at the recent discussion at the Société de Chirurgie. M. Terrier mentioned the case of a woman who, manifestly hysterical, suffered from intolerable pains in the ovaries at the menstrual periods. No relief being obtained by ordinary means, and life being a misery, these organs were removed last February. The right ovary caused no difficulty, but the left was so bound down by adhesions that it could only be extracted piecemeal. Since the operation there has been but insignificant malaise at the catamenial periods, which are perfectly normal. The hysterical condition, although it remains, appears amended; there are no longer any abdominal pains, and the general health is good. This is the second success of the kind obtained by M. Terrier. M. Lucas-Championnière has also performed the operation in two cases: one of his patients died three days after the operation; the other was relieved of her symptoms, and at the same time cured of bad temper. Before the operation she easily became angry at trifles, whereas she is now quite calm. M. Monod said that he also had been successful in two instances, and M. Pozzi was able to endorse the treatment by one operation.

WATER IN INANITION.

The fallibility of authority is amusingly exemplified in the utterances of the *princes de la science*, as it is the custom here to style our leading physicians, concerning prolonged abstinence. A couple of months since the flat went forth that to attempt to live upon water for fifty days was so insensate that no respectable member of the profession should countenance such an experiment. The attempt was made, however, and proved successful, whereupon, after a great deal of big talk about hysterical anorexia and auto-suggestion, our teachers referred to their books, and made the discovery that there was nothing new in the matter, and the profession was urged not to lend themselves to another experiment of the same kind, because they already knew all about it. It is quite possible that the experiments recently made upon animals would have been sufficient by themselves to allow of therapeutical deductions, but it is equally certain that the re-examination of this question, which is not unlikely to lead to some important practical deductions, is the direct consequence of the experiments submitted to by the much-abused Succi, Merlatti, and others. The *Gazette Hebdomadaire* reminds its readers of the case of Viterbi, who to escape the guillotine allowed himself to die of hunger, an end which he achieved after seventeen days of total abstinence both from food and drink. After a few days without food the desire left him entirely, and the only difficulty was in refraining from drink, which he managed, however, by strength of will, only giving way to the terrible requirement of thirst upon two occasions whilst delirious. The author of this article concludes that it is a prejudice to think that hunger is a sensation. We eat by habit, and, as the saying is, *l'appétit vient en mangeant*. To conquer the feeling of hunger it is simply necessary (1) not to eat, (2) to drink. For my own part, I am convinced that abstinence from food will become a recognised therapeutic agent in a near future for the treatment of various diseases, such as those of the stomach in which functional repose is required, and in certain fevers where it may be indicated by anorexia, and possibly also for the absorption of neoplasms. In his interesting code of health and longevity, Sir John Sinclair says that the French surgeon, M. Pouteau, alleviated the pain of cancer, and in several cases even effected a complete cure, by an exclusive diet of water cooled by ice. Pouteau, who was a follower of our Cheselden, was an original worker, and his energy in attacking disease was happily illustrated in the inscription accompanying the portrait facing the title-page of his posthumous works. *Igne et ferro sanabat*, said his editor. Now that the treatment by over-feeding or *gavage* seems to be on the wane, the natural reflux of scientific thought should bring about a movement in favour of abstinence.

ANTIFEBRINE.

The use of antifebrine or acetanilide as a "nervine" was discussed at the last meeting of the Société de Thérapeutique. M. Dujardin-Beaumetz said that it acted as a moderator of the spinal excitability, particularly of the upper portion of the cord. In doses of from 15 grs. to 30 grs. daily no appreciable physiological effect is observed. It cannot be detected in the urine. In three cases of ataxia the "lightning" pains were greatly relieved. In one case of epilepsy the attacks have entirely ceased since its administration. Being insoluble in water, it should be administered either in wine or some other alcoholic vehicle. M. Constantin Paul said that he had tried antifebrine in doses of from 4 grs. to 8 grs. per day, as recommended by Lépine, but without result. A slight improvement was, it is true, observed during the first few days, but this was due, no doubt, to the "moral effect," as exactly similar results were obtained with bread-pills administered under a high-sounding name.

GASEOUS ENEMATA.

M. Blachez testified to the utility of gaseous injections of sulphuretted hydrogen in two cases out of three in which he had recently used them. In the third case some gastro-intestinal irritation was produced, and the improvement of the lung symptoms was not quite satisfactory. M. Paul has devised an apparatus for the administration of these injections, in which the gas is contained in a metallic recipient under pressure, and a manometer registers the quantity which is allowed to pass out.

VIENNA.

(From our own Correspondent.)

TWO NEW SUGAR TESTS.

AT a recent meeting of the Vienna Chemico-Physical Society, Dr. Hans Molisch, assistant at the Phyto-Physiological Institute of Vienna University, described two very delicate tests for detecting sugar in liquids. The reactions employed are the following: A half-cubic centimetre of the liquid containing sugar is mixed with two drops of an alcoholic (15 to 20 per cent.) solution of α-naphthol; then concentrated sulphuric acid is added in excess. In presence of sugar, the liquid if shaken, assumes immediately a deep violet colour, and by adding water to the liquid a blue-violet precipitate is formed. In the other reaction thymol is employed instead of α-naphthol, and the liquid containing sugar assumes a carmine-red colour. These reactions are more delicate (as was shown by experiments) than our common sugar tests, and are successful with most kinds of sugar; they can be also used for proving the presence of sugar in the tissues under the microscope. It was shown also that normal urine of man without any preparation gives

Digitized by Google

the reaction, even if diluted with water to the extent of from 100 to 300 times its volume, and therefore the suggestion that normal urine contains sugar seems to be proved. If normal human urine is diluted with water to more than 300 times, it fails to give the reaction, while urine of diabetic persons can be diluted to a higher degree to exhibit the reaction with α-naphthol.

PREVENTIVE INOCULATIONS IN HYDROPHOBIA.

Dr. Ullmann, assistant of Professor Albert, who has spent some weeks in Paris studying Pasteur's method of preventive inoculations for hydrophobia, has recently established here a station for preventive inoculations. From June 28th till now eighty-five persons bitten by rabid animals were inoculated with the best success. The rabid condition of the animals by which the patients had been attacked was stated in all these cases. According to the reports received, all the patients are in good health.

A NEW HYPNOTIC.

Dr. Ghillany, pharmacologist to the Vienna General Hospital, has succeeded in preparing an alcoholic extract from the roots of Piper methysticum (kava-kava), which is called "extractum kava depuratum." Experiments made with this drug by some physicians of the hospital proved it to be a valuable hypnotic. In all the cases where it was administered sleep was produced, without any disagreeable consequence; even headache, following generally the exhibition of hypnotics, did not occur. It was given, as a powder, from 2 to 5 centigrammes being a dose; or as a suppository containing 2 centigrammes.

SURGICAL DRESSINGS.

In the clinical wards of Professor Albert, experiments are made now with fossil meal (Kieselguhr) as a surgical dressing. The fossil meal is sterilised and mixed with the antiseptic solutions of carbolic acid, sublimate, &c. The cavities of the wounds are stuffed with the paste prepared in this way. The results obtained with this dressing are very good; the wounds show fair granulations, and the process of healing seems to be very much promoted by the mechanical action of the minute particles of the meal.

Vienna, December 23rd.

THE SERVICES.

WITH the approval of the Commander-in-Chief the services of Surgeon A. M. Kavanagh, Army Medical Department, now at Woolwich, and Surgeon J. R. Morse, at Netley, have been placed at the disposal of the Egyptian Government for employment with the Khedive's troops. The former will take up army duties at Abbasiyeh, and the latter will inspect the recruits who are being enlisted in consequence of the reduction of the British garrison.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Herbert Taylor Reade, V.C., to be Surgeon-General, vice Sir Anthony Dickson Home, K.C.B., V.C., granted retired pay; Brigade Surgeon James Landale, M.D., to be Deputy Surgeon-General, vice H. T. Reade, V.C.; Surgeon-Major Alexander Francis Preston, M.B., to be Brigade Surgeon, vice J. Landale, M.D.; Surgeon Herbert Cotton, from half-pay, has been granted retired pay.

ADMIRALTY.—Deputy Inspector-General of Hospitals and Fleets John Breakey, M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

The following appointments have been made:—Fleet Surgeon Charles Strickland, to the Plymouth division of Royal Marines, and Fleet Surgeon Maxwell Rogers, to the *Monarch*.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—The Committee of Management of this hospital have issued their annual report for 1886, from which it appears that of the 2449 in-patients admitted during the year no fewer than 2325 were discharged as improved, and only 48 as no better. The number of out-patients admitted during the year was 248, or twelve fewer than the number admitted during the preceding year. Of these 218 were discharged as improved, and only four as no better. The total receipts from all sources were £276 less than in the previous year, and the average cost per day of each patient has been fractionally under 2*s.* 2*d.*, or nearly one farthing per day more than that of 1885.

Obituary.

WALTER FERGUS, M.D., M.R.C.S.,

LATE MEDICAL OFFICER OF MARLBOROUGH COLLEGE.

THE vast amount of good work done, the untiring energy, and unremitting care bestowed on many, call for more than a passing notice of the death of the late Dr. Fergus, for thirty-seven years the valued and trusted medical officer of Marlborough College. Dr. Fergus was born at Newcastle-on-Tyne in 1819. Educated at King's College, London, and at the University of Edinburgh, he took his M.D. of that University in 1842, and his M.R.C.S. Eng. and L.S.A. in 1843. He became house-surgeon of the Staffordshire General Hospital in 1844, and only resigned this post on being appointed to Marlborough College in 1849. The appointment of Dr. Fergus to Marlborough College was practically the first of its kind, no other public school possessing a resident medical officer. The value of the appointment was soon apparent. Scrupulously punctual and methodical to a degree, he gave his undivided attention to the whole establishment. Boys and staff alike, and all who sought his aid, found a kind and sympathetic friend and adviser. During the thirty-seven years he held the post of medical officer he enjoyed the perfect confidence of the Council of Marlborough College and the successive head masters. Failing health compelled him reluctantly to resign the office in the early part of last year. The uniform work of medical officer, even to a large school, naturally somewhat restricted general practice, but he always kept himself well read in the scientific work of the day, and was a not infrequent contributor to THE LANCET, and his opinion on the subject of public school life in its sanitary relations was highly valued. In the sick-room he was best known: here the patient had not only the competent medical adviser, but the kind and tender nurse; for vast numbers can testify how, night after night, individual cases of gravity received his constant presence and care. It would be impossible in a notice like this to tell of the extraordinary sympathy that existed between the College and Dr. Fergus, and also between him and the town of Marlborough, to many of the residents of which he had endeared himself by acts of kindness and by the interest he took in the parish of St. Peter and Marlborough generally. He was pre-eminently a Christian man, and devoted himself to every good work, was very good and kind to the poor, and he has passed away regretted alike by all.

He died almost suddenly at Ryton-on-Tyne on Dec. 8th. His death, though sudden, was evidently not unexpected by himself, for he had expressed an opinion a short time before that he would not live long. For him death had no terror; he was fully prepared to go forth to meet the shadowy future without fear and with a manly heart. Doubtless, for one like him, who, in his life as a medical man, must have seen many lingering and painful cases, a sudden death may have had its charms. His body was brought to Marlborough on Tuesday, Dec. 14th. An imposing service was held in the new chapel, and by 12 o'clock all that remained of the "good Doctor," as he was familiarly called, was laid to rest in the quiet and beautiful churchyard of Preshute. There it rests close to many old friends, and by the side of some few whose bright young lives had sped—lives which his care and constant watching had failed to save. An immense number of persons attended, testifying to the respect in which he was held.

LAUCHLAN AITKEN, M.D. EDIN.

FOR a wide circle of personal friends and former patients the death of this able and benevolent practitioner invested the closing year with peculiar sadness. Dr. Aitken went to Rome about fourteen years ago—himself an invalid from the sequelæ of a severe attack of scarlatina,—and in that genial climate he soon recovered strength enough to resume the professional career which had become impossible in "the grey metropolis of the north." He brought with him many qualifications for the success he rapidly achieved. Having graduated at Edinburgh with much distinction both in surgery and in medicine in 1865, he took the "summi in medicinâ honores" in 1868. Prolonged visits to

Digitized by Google

the chief continental schools, such as Berlin, Vienna, and Paris, extended and deepened the medical proficiency which had already attracted the attention of Sir J. Y. Simpson, to whom he became assistant both in the class-room and at his private residence. A brilliant career was now before him, until the malady above referred to compelled a complete change of plan, and induced him to settle in Rome in 1872. He then applied himself with characteristic energy and decision to master the climatic conditions of the place, and his studies on the local fever fructified in more than one able and instructive paper in the London and Edinburgh journals. He was a trenchant vindicator of the sanitary credit of Rome, particularly as to her water-supply and (till lately) as to her immunity from typhoid, and as soon as the growth of the city, the increase of the population, and the altered conditions of the water-supply and the drainage appeared to invite that scourge, he endeavoured by interviews with the hotel proprietors, and by letters in the local journals, to minimise the evil at its source. A reprint of his papers on the Climate, the Malaria, the Water-supply, and the Health Statistics of Rome would be welcomed not only by English-speaking practitioners, but by those of the many different nationalities domiciled in the Eternal City.

About three years ago the cares of an extensive and laborious practice—involving much mounting of hotel stairs—began to tell on his imperfectly nourished heart, and threatenings of asystole admonished him to relax the strain. Intimate professional friends, indeed, urged him strongly to withdraw from practice entirely, at least for a few seasons; but nothing would shake his resolution to die at his post. He lived for ministration at the bedside; it was his mental resource and predilection, and all appeals to spare himself were answered with a

Propter vitam vivendi perdere causas?

The result soon became manifest in an increasing recourse to substitutes, until his return to Rome at the commencement of the season, with "the wheels of life run down," convinced him that his professional career was at its close. He lingered for a few weeks under the sedulous care of Dr. Edmonston Charles, sometime of the Bengal Army and late of Cannes, to whom he had transferred his practice, and on Sunday, the 19th ult., he sank, conscious to the last.

Dr. Aitken was but forty-three years of age when he died, but he lived long enough to impress a wide *clientèle* with his admirable skill and success as a physician, and a still wider circle of friends with his manly integrity, his catholic tastes, and his benevolent heart. He was buried on the 24th ult. in the Protestant cemetery between the Tiber and the Gate of St. Paul.

W. A. N. CATTLIN, F.R.C.S.

ON the 13th ult. there passed away from our ranks one whose name will long be held in honour for his scientific attainments and his skill in dental surgery. No less durable will be the memory of his single-hearted and unselfish generosity, for he was ever ready to lend a helping hand whenever a claim commended itself to his judgment.

Mr. Cattlin was born at Southend in the year 1814. He was apprenticed to the late Mr. Porter, of Bishopsgate-street, London, received his medical education at the London Hospital, where he gained prizes in medicine, and was highly esteemed for his acumen and sagacity by the late Dr. Billing. He became a Licentiate of the Apothecaries' Company in 1836, a Member of the College of Surgeons in 1841, and a Fellow in 1856. He commenced practice in the City-road, London, but, on account of ill health, was compelled to abandon it and take a voyage. After his return, with renewed health and energies, Mr. Cattlin became resident medical officer at the Holloway and North Islington Dispensary, and soon afterwards, in Islington, entered upon the practice of dental surgery, of which he had previously obtained good practical knowledge. In this branch of the profession he soon attained to eminence. He was one of the founders, and sometime president, of the Odontological Society. It was mainly to the untiring exertions of Mr. Cattlin that the Medical Benevolent College owes its present satisfactory basis.

In 1863 Mr. Cattlin removed to Brighton, where his great success followed him, but his health broke down under stress of work, and he retired to Bournemouth in 1880, but never recovered from the effects of an attack of paralysis, to the later effects of which, indeed, he ultimately succumbed. Mr. Cattlin's quick intelligence and decision in acting inspired confidence in his professional opinion, whilst his genial and kindly disposition gained him countless friends. He was attended, at various periods of his illness, by Mr. Jonathan Hutchinson, Dr. Hughlings Jackson, Dr. Wilks, Mr. Power, and others. He leaves a widow and several children, one of whom, Mr. Wm. Cattlin, follows his late father's profession.

Medical News.

THE Gresham Lectures on Physic will be delivered by Dr. Symes-Thompson, on Feb. 8th, 9th, 10th, and 11th.

DR. A. FRASER has been appointed Deputy-Coroner for the Totnes district, South Devon, vice Mr. Jelley, resigned.

THE Hospital for Women, Soho-square, has petitioned Her Majesty in Council for a charter of incorporation.

ON the 31st ult. a very successful fancy dress ball was held at Faversham, in aid of the proposed local cottage hospital.

A SPECIAL service was held on the 26th ult. at the Hope-place Synagogue, Liverpool, on behalf of the local medical charities. The offertory amounted to £21.

MR. THOMAS MOORE, F.L.S., who for thirty-eight years was curator of the Botanic Garden of the Society of Apothecaries at Chelsea, died there on New Year's Day, in his 66th year.

"HOSPITAL SATURDAY" has been transplanted to New York, and it is expected that by next year the work will, by the aid of women's auxiliary societies, be thoroughly systematised.

ON the 28th ult. Mr. Peter White, surgeon, of Yetholm, near Kelso, suddenly fell down dead in the village. It is noteworthy that Mr. White's wife also expired suddenly on the previous Saturday.

AT a largely attended meeting of the Great Yarmouth Jubilee Committee on the 4th inst., it was agreed that the local commemoration should consist of a jubilee wing for the Yarmouth Hospital.

ACTION FOR LIBELING SCIENTIFIC MEN.—An action has been brought by order of the German Chancellor against Dr. Oidtmann, editor of the *Impfzwanggegner* (Anti-compulsory vaccinationist) for libeling Prof. Koch and Privy Councillor Köhler.

THE Canadian correspondent of the *Liverpool Journal of Commerce* says, "Dr. Dodd has been making tests of the mineral waters found near Regina, with the most satisfactory results. He has now established beyond doubt the fact of their strength and general curative purposes."

THE Birmingham Hospital Sunday Collection Committee have handed over to the treasurer of the General Hospital £4231 as the result of the last collection. The total sum realised was £4662. The balance, after payment of expenses, has been given to other charities.

OPEN SPACES IN MANCHESTER.—The committee for securing open spaces for recreation are just now making increased efforts to obtain public support on behalf of the work they are carrying on, and ask for £1500 to furnish and lay out several spaces and gymnasia that they have in hand.

BRITISH HOSPITAL AT PORT SAID.—Sir John Stokes, who is chairman of the London committee for building a British hospital at Port Said, has, it is stated, obtained an excellent site near the sea in exchange for the site formerly granted. The hospital will now be begun at once, and, it is hoped, will be opened in April.

SANITATION IN KIDDERMINSTER.—During the past year the improvements in the sewerage system of Kidderminster have been completed and the new covered reservoir opened. The provision of a sufficient water-supply from a source free from sewage still, however, demands attention. The lower well, the condition of which at the beginning of last year caused much anxiety, is still being used, but we trust that the Town Council is alive to its responsibility, and that the provision of another source for the water-supply may only be a question of weeks or months.

Digitized by Google

HOSPITAL FOR INCURABLES, MANCHESTER.—Temperance reformers will be pleased to note a statement made at the recent annual meeting of the Manchester Hospital for Incurables, that though the patients had numbered upwards of eighty during the past twelve months, only £13 had been expended upon wine and spirits.

INFIRMARY ACCOMMODATION AT CAMBERWELL.—The Camberwell Board of Guardians have adopted a report from a committee, recommending that additional infirmary accommodation should be provided for about 350 adults and fifty children. The present infirmary, which is completely filled, contains 230 beds.

THE St. Marylebone Infirmary, Rackham-street, Notting-hill, was, on the 30th ult., thrown open for inspection by the ratepayers of the parish and others interested in the management of such institutions. At the close of the visit entire satisfaction with the management of the building was expressed.

PRESENTATION.—On the 30th ult., at West Hartlepool, James Atkinson, M.D., was presented by the brethren of the Good Intent Lodge of the Manchester Unity of Oddfellows with an address in recognition of his services to the lodge during the thirty-four years he acted as its medical officer, a post which he has recently resigned.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—A quarterly general meeting was held at 11, Chandos-street, on Tuesday last, the president, Dr. Norman Kerr, in the chair. Mr. Tudor Trevor read a paper on the Prevailing Indifference to Inebriety. Dr. H. W. Williams, Mr. Hilton, Mr. Raper, Mr. Gustafson, and Mr. Frederick Trevor took part in the discussion.

A HOSPITAL AS A THANK-OFFERING.—The Nursery Hospital, the Jubilee gift to Buckingham of Mr. J. G. Hubbard, M.P., and Mrs. Hubbard, and which has cost about £4000, will be ready for opening in a few weeks. It bears an inscription to the effect that it is offered in thankful remembrance of the preservation from sudden death by an accident to Mr. Egerton Hubbard, M.P., in 1874.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARRETT, W. A. H., L.R.C.P.Lond., L. & M.S.A., has been appointed Medical Officer and Public Vaccinator for the Littleport District of the Ely Union, and the South Welney District of the Downham Union.

BLACKETT, W. CUTHBERT, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Durham Rural Sanitary District.

BOYS, ARTHUR H., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer and Public Vaccinator for the Second District of the St. Alban's Union.

CAMPBELL, DONALD, M.D., C.M.Glas., has been reappointed Medical Officer of Health for the Calne Rural and Urban Sanitary Districts.

CLARKE, A. B., L.R.C.S.Ed., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Shebbear District of the Torrington Union, Devon.

COLLENETTE, F. DE B., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer of Health for the Wolstanton and Burslem Rural Sanitary District.

DA'ATH, GEORGE H., M.R.C.S., has been reappointed Medical Officer of Health for the Buckingham Rural Sanitary District.

DUNCAN, DAVID, M.B., C.M.Aber., S.Sc.Dur., has been appointed Medical Officer of Health for the Chester-le-Street Rural Sanitary District.

FENWICK, CHARLES, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Dunsford District of the Exeter Union.

GRAHAM, WM., M.D.Roy.Univ.Irel., L.R.C.S.Ed., has been appointed Resident Medical Superintendent of Armagh District Lunatic Asylum.

HARDY, ALBERT E., M.R.C.S., L.S.A., has been appointed Senior House-Surgeon to Charing-cross Hospital.

HAWKINS, FRANCIS, M.B., has been appointed Physician to the North London Hospital for Consumption and Diseases of the Chest.

HAYNES, CHARLES, L.S.A., has been appointed Electrical Assistant to Charing-cross Hospital.

HOCKEN, J. PRESTON, L.S.A., has been appointed Resident Obstetrical Officer to Charing-cross Hospital.

HUDSMITH, POWELL, L.K.Q.C.P.I., has been appointed Medical Officer of Health for the St. Anne-on-the-Sea Urban Sanitary District.

LAKIN, CHARLES, L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the First District of the Leicester Union.

LITTLEWOOD, JOHN OSCROFT, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Borough of Walsall.

LUCY, REGINALD H., M.B., C.M.Edin., M.R.C.S., has been appointed House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth, vice W. A. Buchan, M.B., C.M.Edin., L.S.A., resigned.

MACDONALD, P. WM., M.D., C.M.Aber., has been appointed Medical Superintendent to the Dorset County Asylums, vice J. G. Symes, M.R.C.S., &c., resigned.

MAKINS, G. H., F.R.C.S., Assistant Surgeon to St. Thomas's Hospital, has been appointed Demonstrator of Anatomy to that Institution.

MASON, SAMUEL BUTLER, M.R.C.P.Ed., L.F.P.S.Glas., has been re-appointed Medical Officer of Health for the Pontypool Urban Sanitary District.

MEAD, H. T. HARVEY, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Christchurch, Hants, Urban Sanitary District.

MOORE, CHARLES ARTHUR, M.D.Aber., has been reappointed Medical Officer of Health for the Barrow-on-Soar, Billesdon, Blaby, Hinckley, Lutterworth, Market-Bosworth, Oakham, and Uppingham Rural Sanitary Districts; and the Melton-Mowbray and Thurmaston Urban Sanitary Districts combined.

NELHAM, ALBERT E., M.R.C.S., L.S.A., has been appointed Junior House-Surgeon to Charing-cross Hospital.

NORRIS, EDWIN J., M.R.C.S., L.R.C.P., L.S.A., has been appointed Senior House-Physician to Charing-cross Hospital.

OLIVER, W. PYE, L.S.A., has been appointed Junior House-Physician to Charing-cross Hospital.

STARLING, EDWIN A., M.B., M.Ch., &c., has been appointed Honorary Medical Referee for the District of Tunbridge Wells, and to the National Hospital for Consumption at Ventnor.

TURNER, FREDERICK, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Buxton Urban Sanitary District.

WILSON, ROBERT A., M.D., C.M.Glas., has been reappointed Medical Officer of Health for the Lunesdale Rural Sanitary District.

Births, Marriages, and Deaths.

BIRTHS.

HANLEY.—On the 31st ult., at 3, Upper Phillimore-gardens, Kensington, W., the wife of Edward Hanley, M.D., M.Ch., of a son.

HERRON.—On the 3rd inst., at Southwark-bridge-road, the wife of J. Herron, M.D., of a son.

HETLEY.—On the 30th ult., at Church-road, Upper Norwood, the wife of Henry Hetley, M.D., of a son.

MARTIN.—On the 29th ult., at Brunswick-street, Sheffield, the wife of J. W. Martin, M.D., of a son.

RICE.—On the 25th ult., at Sutton, Surrey, the wife of Geo. Rice, M.B., of a son.

MARRIAGES.

ANDERSON—KITCHING.—On Nov. 30th, at Cape Town, G. E. C. Anderson, M.D.Lond., late House-Physician, Guy's Hospital, to Alice, eldest daughter of C. W. Kitching, M.B.Lond., of Cape Town.

DWIGHT-MORRIS — NOAKS. — On New Year's Day, at St. Stephen's, Hornsey, by the Rev. Joseph Kahn, M.A., Colin Dwight-Morris, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A.Lond., of Feltham, Middlesex, to Nellie, eldest daughter of the late George Noaks, retired Captain, B.M.P.S., Calcutta.

ERSKINE-RISK — FADDY. — On the 13th ult., at St. Luke's Church, Juliadhar Cantonment, Punjab, Surgeon E. J. Erskine-Risk, Army Medical Staff, to Ellie Mary, youngest daughter of Maj. L. P. Faddy, late 29th Regiment, Bengal, N.I.

FOX—DANGER.—On the 30th ult., at the Parish Church, Brislington, near Bristol, Bonville Bradley Fox, M.A., M.D., to Annie, youngest daughter of the late Thomas Danger, Esq., of Gotley Lodge, Brislington.

PORTER—COWAN.—On the 7th ult., at Paget Parish Church, Bermuda, James Porter, M.A., M.B., Surgeon, R.N. Hospital, Bermuda, to Emma Louisa Kay, eldest surviving daughter of Deputy Inspector-General M. W. Cowan, M.D., R.N.

WHITE—FRIPP.—On the 30th ult., at the Parish Church, Tarrant Rushton, Dorsetshire, by the Rev. James Penny, Rector, uncle of the Bride, William Hale White, M.D., of 65, Harley-street, W., eldest son of Wm. Hale White, of Carshalton, to Edith Jane Spencer, youngest daughter of Alfred Downing Fripp, Esq., R.W.S., of Hampstead.

DEATHS.

ANDREWS.—On the 3rd inst., at New Barnet, Charles Andrews, M.D., of Hammersmith-road, W., aged 59.

BARON.—On the 27th ult., at Woodland-terrace, Plymouth, Edward George Baron, M.R.C.S., late of Ulceby, Lincolnshire.

BOMPAS.—On Nov. 3rd, at Busselton, Western Australia, Charles Smith Bompas, M.R.C.S., formerly of Bristol and Manchester, aged 68.

BROWNE.—On the 20th ult., at Rhyl, North Wales, after a brief illness, Harry Duncan Bouchier Browne, M.B., of University College, Glasgow, and House-Surgeon to the Flintshire Dispensary, in his 24th year.

CURME.—On the 2nd inst., at Dorchester, George Curme, M.R.C.S., L.S.A., in the 80th year of his age.

HOLMES.—On the 31st ult., at San Remo, Surgeon-Major A. P. Holmes, 1st Sikhs Infantry, aged 51.

JACKSON.—On the 23rd ult., William Jackson, M.D., late of Kingsland-road, aged 75.

LINTON.—On the 29th ult., at Ashley-court-villas, Ashley-hill, Bristol, Cornelius Clarke Linton, Inspector-General of Hospitals, late Indian Medical Service, in his 84th year.

MACKENZIE.—On the 18th ult., at Eileanach, Inverness, N.B., John MacKenzie, M.D., aged 83.

MOORE.—On the 1st inst., at Much Hadham, Herts, Francis Moore, M.D., aged 80.

RANGER.—On the 27th ult., at Bexley-heath, Kent, Frederick Ranger, M.R.C.S., late of Cranbrook, Kent, aged 67.

SELLERS.—On the 28th ult., at John-street, Rochdale, William Burdett Sellers, M.R.C.S., L.S.A., aged 67.

SMART.—On the 26th ult., suddenly, at Queen's-crescent, Glasgow, Robert Smart, M.D.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 10.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Communications by Messrs. L. Matheson, C. D. Davies, W. St. George Elliott, A. S. Underwood, S. J. Hutchinson, Morton Smale, and Joseph Walker. President's valedictory address.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Ralfe: Phosphatic Diabetes.—Mr. A. Pearce Gould: A Case of Wound of the Common Femoral Artery.

Tuesday, January 11.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Mr. George Watt: A Brief Account of the Aboriginal Races of Manipur and the Naga Hills.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Bland Sutton: Suture of the Median Nerve Ten Weeks after Division, with Recovery of Function.—Dr. Eccles: Observations on the Physiological Effects of Massage (communicated by Dr. Lauder Brunton).—Mr. Barwell: On Widely Incising by a Two-stage Method Hydatids of the Liver.

Wednesday, January 12.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

HUNTERIAN SOCIETY.—8 P.M. The President: Cases of Lead Poisoning terminating rapidly with Cerebral Symptoms.—Dr. Fox: The Nature of Asthma.—Dr. Turner: Actinomycosis of the Liver.—Mr. Symonds: Further History of a case of Intestinal Obstruction.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Mr. Edward F. Willoughby: Preventive Inoculations.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Amand Routh and others. Dr. Pedley: Midwifery among the Burmese.—Dr. Herman: Stricture of the Female Urethra.—Dr. Gibbons: Case of Unilateral Galactorrhœa.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. A. W. Bennett: Freshwater Algæ (including Chlorophyllaceous Protophytæ of North Cornwall), with Descriptions of Six New Species.—Mr. J. Mayall, jun.: A Visit to Jena.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Annual Meeting. Presidential Address.

Thursday, January 13.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, January 14.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Annual General Meeting for the Election of Officers and Council.—Dr. Samuel West: Right Hemiplegia with Aphasia occurring during a paroxysm of Whooping-cough, with slight rigidity, subsequently passing into a condition of Athetosis.—Mr. Mayo Robson (Leeds): (1) A Method of Treating Thyroid Cysts; (2) A Suggested Method of Operating on a Uniform Principle in the Treatment of Imperforate Anus. Living Specimens:—Dr. Radcliffe Crocker: A case of Athetosis after Hemiplegia.—Dr. Stephen Mackenzie: Living Embryo Filariæ Sanguinis Hominis from a case of Chyluria.

Saturday, January 15.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE QUEEN'S JUBILEE.

How shall we honour, as we honour should,
A Queen whose reign has been so long, so good?
By statue; portrait; eulogistic verse?
We might do better, hardly could do worse.
Let's build a hospital in every town;
Endow it well, though carping niggards frown.
On every town impose a trifling tax,
That help, in time of need, be never lax.
Let all creeds, needing, share the nation's love;
So shall this Jubilee a blessing prove
To all on England's soil in time to come,
When England's Queen rests in a royal tomb.
Then millions, yet unborn, shall thank kind heaven—
Our Queen was loved in eighteen eighty-seven.

Christmas Day, 1886. BART. ROUS.

Mr. A. F. Harrison.—Since the well-known works of Bazin and Hardy, French dermatological literature has, with the exception of a few manuals and volumes of lectures, been almost entirely limited to monographs and contributions to periodicals. Hillairet's work was not completed. French translations of Neumann's well-known work from the 4th edition (13 fr.), and of Kaposi's writings, have appeared. Lailler's "Leçons sur les Teignes," 1878; Bazin's "Leçons sur les Affections Cutanées Parantaires" (5 fr.), and the articles in the large French dictionaries are valuable. Any work required, or information, could be obtained of the foreign booksellers.

G. B.—The report is noticed on another page in our current issue.

DR. GOTO'S METHOD OF TREATING LEPROSY.

To the Editors of THE LANCET.

SIRS,—In your last issue reference is made to Dr. Goto's method of treating lepers. The remedies he gave to a patient of mine I have brought to England for analysis, and I hope shortly to place them in the hands of the College of Physicians, with a few remarks on the case of the boy to whom he gave them.

I remain, Sirs, yours truly,

G. W. PARKER, M.R.C.P.L., F.L.S.
(Late of the Hawaiian Board of Health Service.)

Christchurch, Hampshire, Jan. 1st, 1887.

John Eliot, Esq.	1	1	0				

Dentists.—It is common enough and right enough for different members of a family to have different medical men. It is neither right nor common for medical men to allow or encourage touting on their behalf.

Odours.—Yes. Two American physicians, Drs. Nichols and Bailey, have recently conducted experiments which, they believe, prove that the sense of smell is more acute in men than in women.

IMPERFORATE HYMEN.

To the Editors of THE LANCET.

SIRS,—Having read recently in your journal some cases of imperforate hymen with menstrual retention, I send you the following case that occurred to me whilst surgeon to the Panulcillo Copper Companies' Mines in Chili.

B—— P——, aged eighteen, had never menstruated. For twelve months she had experienced acute pain in the abdomen at variable periods. I was called in on Nov. 25th, 1882, by the father, who stated that his daughter was in great pain, and that something soft was protruding from the vulva. The patient refused examination; so an opiate was given, and relief obtained. On Dec. 18th I was called again, when the pain was so severe that an examination was readily consented to. In the hypogastrium I found a hard rounded tumour, the size of a small melon, extending from the pelvis to within an inch of the umbilicus. From the left side of the upper extremity of this tumour was a protrusion, an inch in diameter, extending at right angles for about three inches. Per vulvam a tough red membrane projected from between the lips, which was tense but fluctuated. A catheter was used, and the bladder emptied. A small exploring trocar was introduced into the centre of the tumour, a flow of thick, almost black, retained menstrual fluid resulting. This fluid was allowed to flow from the trocar until relief from pain was obtained. On Dec. 19th a crucial incision was made in the membrane, and an injection of Condy's fluid, one drachm to the pint of water, freely used. No clots passed. From this date the patient made an uninterrupted recovery, and I found her up and about on Dec. 27th. She has since menstruated regularly and without trouble of any sort, and married on March 26th, 1886.

I am, Sirs, yours faithfully,

ARTHUR GRAYLING, M.R.C.S., L.R.C.P. Lond.

Forest-hill, S.E., Dec. 27th, 1886.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

To the Editors of THE LANCET.

SIRS,—I am desired by the Council to send you a copy of a letter written by the master of the science class at Epsom College to the headmaster, and to say that they will be extremely obliged to you if you will find room in THE LANCET for the communication, in the hope that in this way the want may be supplied.

I am, Sirs, your faithful servant,

Jan. 3rd, 1887. ROBERT FREEMAN, Secretary.

"DEAR MR. WOOD,—We are greatly hampered in the study of zoology by the want of a number of skeletons. It has occurred to me that if this want were known to the medical profession in London, say by means of a letter in the medical papers, or by the intervention of a Member of the Council, it might be remedied. I think it is not unlikely that at some of the hospitals there may be extra specimens that they would be willing to present to Epsom College. If asked what particular skeletons wanted, I should say those mentioned in the honours list for intermediate B.Sc. and in the B.Sc. list for the University of London. These would also cover the work for scholarships at Oxford or Cambridge. I should be very glad if you would represent this matter in the proper quarter. "I remain, yours very truly,

The Rev. W. Cecil Wood." "J. S. JACKSON."

COCAINE.

To the Editors of THE LANCET.

SIRS,—With reference to the letter in your last issue relative to cocaine, my experience is that if absolute insensibility of the part is required a 20 per cent. solution is necessary. I have on two occasions removed a sebaceous cyst, measuring two inches in diameter, from the neck, and on each occasion the patient calmly smoked a cigarette during the operation.

I am, Sirs, yours faithfully,

Southsea, Jan. 1st 1887. ALBERT BENTHALL.

FRENCH LUNATIC ASYLUMS.

THE supervision of French lunatic asylums appears, if recent accounts be true, to be exceedingly lax. It will be remembered that a short time ago a man was released from an asylum, having been forty years previously confined by his relatives in order to secure his wealth. The escape of another man is now reported, who, although sane, was confined for a year in an ill-lit room, bound hand and foot. Such treatment is strictly forbidden by law, and the matron and two keepers of the establishment have been fined, and the medical superintendent condemned to a fortnight's imprisonment. Such regrettable and scandalous incidents would be impossible if any control were exercised by the authorities; and although our Gallic neighbours may manage things in general better than we do in England, their most ardent admirers will be compelled to admit that the protection of lunatics and the supervision of asylums do not redound to their credit.

Mr. Barnes Nowell writes us in explanation of his action as described by "Verax." We are of opinion that it was due to the gentleman in attendance to have sought his concurrence in the step taken, or to have communicated with him immediately in explanation of the urgent circumstances.

A Subscriber.—Such a place as St. Mary Church, near Torquay, would meet most of our correspondent's requirements.

SUICIDE AFTER TAKING A DOSE OF CHLORAL.

To the Editors of THE LANCET.

SIRS,—Perhaps you may be able to find a corner for the following case.

On Nov. 17th I visited P. D——, a somewhat anæmic man, about thirty years of age, who was suffering from bronchitis. There was a history of an acute, painful, spasmodic disease of the chest, which the patient believed to be asthma, but which I thought was angina pectoris. He was treated for the bronchitis, and all went fairly well until the morning of Nov. 22nd, when, being in acute pain, he persuaded a friend, an apothecary, to give him fifteen grains of chloral hydrate. Almost immediately after taking the chloral he procured about six ounces of French brandy, which he imbibed in three doses during the space of about an hour. After the third dose of brandy a friend who was with him left, observing before leaving that the patient's face was flushed in patches. After the departure of his friend the patient shot himself through the brain with a revolver, and was found dead in bed by myself. He was poor, but not in any difficulty of any consequence, and beyond slight despondency had not shown any symptoms of insanity either to myself or to his friends.

I see that Dr. C. Browne mentions "deep flushing of the face," and Dr. Fuller "violent delirium," after the administration of chloral. Perhaps some of your readers would inform me, first, whether any case of suicide following the administration of chloral has been recorded, and, secondly, whether it is their opinion that the chloral, or the mixture of chloral and brandy, was responsible for the suicidal action.

I am, Sirs, yours obediently,

South Africa, Nov. 25th, 1886. A. P. G.

Student will not be able to register the M.R.C.S. *alone* after June next. He must show that he has passed a qualifying examination in medicine, surgery, and midwifery, as defined by the Act; and this requires the co-operation of corporations.

Mr. Habgood and *Mr. Cooper.*—An ounce powder was intended.

EXPLORATORY INCISIONS.

To the Editors of THE LANCET.

SIRS,—In your issue of Nov. 13th, page 910, second column, forty-second line, Mr. Bryant, in his admirable address on the value of exploratory incisions, is represented as saying, "The cavity was washed out with iodine water and packed with strips of iodoform gauze, so as to promote suppuration." He certainly did not mean to say this, as iodoform gauze is used to *prevent*, not "promote," suppuration; and this is corroborated a few lines lower down, where it is stated that no pus was found when the packing was removed.

I am, Sirs, yours very truly,

Chicago, Dec. 23rd, 1886. D. A. K. STEELE.

Mr. Thos. Lafan.—The University of Oxford recognises for its diploma no medical examinations other than those conducted by itself.

MEDICAL DEFENCE.

To the Editors of THE LANCET.

SIRS,—In order to prevent possible misunderstanding, will you kindly permit me to inform your readers that the Medical Defence Union, whose circulars are being sent to members of the profession, has no connexion whatever with the Medical Defence Association, of which Dr. B. W. Richardson, F.R.S., is president.

I am, Sirs, yours faithfully,

GEORGE BROWN,

Hon. Sec., Medical Defence Association.

King William-street, E.C., Jan. 3rd, 1887.

Digitized by Google

MORPHIA HABITUÉS.

To the Editors of THE LANCET.

SIRS,—I am desirous of collecting as much information as possible concerning the after history of cured morphia habitués, particularly (1) any special hygiene adopted by those who have passed some time without relapse, (2) evidence of the necessity (or the contrary) of subsequent total abstinence from alcohol, (3) any special tendency to relapse in gouty subjects in consequence of some particular distress or restlessness, (4) the value of valerian and its preparations, and (5) cases where opiates have subsequently been given with benefit and impunity. I should be greatly obliged to those interested in this question who will favour me by communicating their experience. Any information sent to me personally would, of course, be acknowledged if used for publication.

I am, Sirs, yours very truly,

Paris, Dec. 20th, 1886. OSCAR JENNINGS, M.D.

Mr. G. W. Parker.—We fear our space will not permit of the publication of the notes and statistics.

P. H. W.—There does not seem to be anything novel in our correspondent's suggestions.

Dr. C. F. Knight's paper is marked for insertion.

"ABSCESS OF THE LIVER IN INDIA."

To the Editors of THE LANCET.

SIRS,—I have just seen Mr. Curran's letter in your issue of Nov. 6th, and I hasten to acknowledge that I have derived much valuable information from his exhaustive treatise on Hepatitis in India, a work to which I have on more than one occasion referred in print. As regards the case in question of seven abscesses found at the post-mortem examination in the liver of an infant six months old, from the description published in the *Indian Medical Gazette* it was a case of general peritonitis; and it appears to me that the multiple abscesses must have been either tubercular or pyæmic, not true tropical abscesses, of which class alone my paper treated.

I am, Sirs, yours truly,

A. TOMES, M.D., Surgeon, I.M.S.

Midrapore, Bengal, Dec. 8th, 1886.

Voyageur.—Montreal is not exempt from enteric fever, which usually begins to assume an epidemic form in October.

X. Y. Z.—We believe the evidence available is insufficient to warrant a conclusion in the affirmative.

M.D. is referred to announcements in our advertising columns for information on the subject.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Sydney Jones, London; Dr. Maclagan, London; Mr. W. Curran; Dr. Stephen Mackenzie, London; Dr. Savage, London; Dr. Norman Kerr, London; Mr. Banstone, Torrington; Dr. Luca, Chelsea; Messrs. Clinical Lecture
ON
SOME FORMS OF DEFECTIVE SPEECH.

Delivered at St. George's Hospital,

BY WARRINGTON HAWARD, F.R.C.S., &c.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—You have lately seen two children operated upon by me for cleft palate, when I devoted a clinical lecture to explaining to you the character of that defect and the method which I proposed to adopt for its cure. I had not time then to do more than very briefly allude to the management and instruction of these children which are necessary when the operative treatment is complete. To-day, therefore, I wish to call your attention to the measures which should be used for improving the speech after the cure of a cleft palate, and also to say something about the treatment of some other defects of speech in children.

Now you will frequently have occasion to observe, where an erroneous habit is acquired in consequence of some defect, deformity, or disease, that even when the cause of such habit is removed, some pains are needful to overcome the persistence of the habit itself. For instance, a child who has been accustomed to wet the bed at night, in consequence of the irritation of an adherent prepuce, may be cured at once by circumcision if the condition is but of recent occurrence; but if the incontinence of urine is of long duration, the immediate effect of the operation is not always a complete cure; the habit of emptying the bladder early in the night may still to some extent show itself, and not until a few weeks have passed, and some trouble has been taken, is the habit overcome. So, again, the awkward gait in some forms of paralytic talipes, due to the distorted position of the foot, is not instantly remedied by bringing the foot into the normal position. Some education is needed of the muscles, which have long been acting under disadvantageous mechanical conditions.

So, then, you will observe that a child with cleft palate uses its tongue and palatal muscles in a manner quite different from one with the natural condition of palate, and that even after a complete closure of the cleft there is still some awkwardness of speech. This varies greatly in different individuals, partly because of differences in the shape of the part, and partly because of variations in the intelligence of the learner; but all of them will be greatly assisted by proper instruction. This instruction must be directed towards unlearning the manner of using the tongue and palate which has been resorted to by the child in consequence of its cleft palate, and acquiring the right method of using these parts. It must be carried on by means of systematic lessons and practice regularly gone through day by day for months or even years; and is usually, therefore, among intelligent persons, best managed by one or other of the parents. But the parent must be taught how to proceed; and it is often of great advantage, especially in bad cases, to obtain at the commencement the help of one of the teachers specially trained for teaching deaf-mutes to speak.

The plan I recommend for this, and for other defects of speech to which I shall presently allude, is as follows:—The instructor should sit directly facing the pupil; the pupil is made to fix his attention thoroughly upon the face of the teacher, and to copy slowly his method of articulation. This should be displayed by the teacher in an exaggerated degree, every movement of the lips and tongue being made as obvious as possible to the pupil, and the more difficult sounds or movements prolonged for the purpose. Thus, for instance, suppose the word "sister" were to be practised, the teacher, having filled his chest by a long inspiration, would open his lips and draw back the angles of the mouth, so that the pupil could see well the position of the tongue against the teeth; he could then prolong the hissing sound of the "s," and finally, separating the teeth as the sound of the "t" in the second syllable issues, allows the pupil again to see the position of the tongue as the word is ended. Or, for another example, take the word "lily." Here the teacher would separate the lips and teeth, so that the tongue would be seen curved upwards, with its tip touching the hard palate; the word would then be pronounced with a prolongation of each syllable, the teeth and lips being kept open so that the uncurling of the tongue and its downward movement are clearly seen. So again, in teaching the proper method of sounding such words as "ning" or "youth," much aid is given by keeping the lips somewhat separated, so that the relation of the tongue and palate can be made manifest. The pupil must be made to fill his chest, and then to imitate as closely as possible every movement and sound of the teacher, and this may sometimes be assisted by making the pupil feel with the finger, as well as observe with the eye, the relative movement and position of the teacher's tongue and palate. There should be no other person in the room to distract the attention of the pupil. It is best to continue the exercise for a short time only, and to repeat it frequently, rather than to fatigue the child by a long lesson; and it is a good plan to take an ordinary elementary spelling-book, and to mark the words which the pupil finds most difficult to pronounce, so that these may be specially practised. I wish especially to insist upon the importance of making the pupil fix his entire attention upon the face of the teacher in all attempts to remedy defective speech, for this does not seem sufficiently understood. Yet, if you will take an ordinary child of three years old, and tell it to repeat a difficult word after you while you stand behind it, and then make the child say the same word while it looks at your face, you will see at once the great advantage of the latter method. And this applies to adults as well as children.

Instances are occasionally met with of children with very highly arched palates who speak very much like those with cleft palates. The speech of these children may be very greatly improved by such teaching as I have described; but if they are allowed to grow up without any such aid, it becomes very difficult to make them speak plainly. In one such case—a girl seventeen years of age—it was almost impossible for one not accustomed to the speech of those with cleft palate to understand what she said; so that at shops, railway stations, and with strangers generally, she was obliged to write down what she wished to say. She was very anxious to know if anything could be done for her by surgery; and so, after explaining to her that the operation was an experimental one, I decided to try the effect of lowering the arch of the palate by bringing down the soft parts from the hard palate (as in the operation for closing a cleft), cutting away a piece from the middle line, and then sewing the edges together again. The incision healed well, and the result of the operation was that her palate was reduced to the ordinary level. When the tenderness resulting from the operation had subsided, she was found to speak somewhat more distinctly. The alteration, however, was not great at first; but after a few weeks of practice the girl's speech very much improved; and when I saw her some months afterwards she gratefully told me that everyone could now understand her quite well, and that her friends, as well as herself, were much pleased with the improvement. Her speech was still, however, far from perfect.

I have also seen a few cases in which, besides the palate being highly arched and narrow, the inter-maxillary bone has been thrust forward, as though squeezed out of place by the approximation of the two halves of the upper jaw-bone. This condition is accompanied by indistinct speech of the kind above described. In these cases great improvement may be effected by gradually pushing back the projecting process of bone by means of an apparatus adapted by the dentist and constantly worn by the child, care being taken at the same time to educate the child in the proper method of speech.

Then there is another class of children who exhibit defects of speech dependent upon cerebral causes. It is a not uncommon occurrence to have children brought to one because the mother has noticed with anxiety their extreme backwardness in beginning to speak. The mother thinks or hopes that there is something wrong about the mouth or palate to account for this. But one finds on examination that the parts concerned in speech are quite natural,[1] and that the backwardness in speaking is only the more obvious part of the general intellectual deficiency, of which other signs are discoverable on investigation. Very often the

[1] The teeth of such children are usually late in their eruption, and defective, and the jaw often narrow and ill-developed; but this is only a concomitant, not a cause, of defective speech.

Digitized by Google

expression of the child's face is in itself sufficient to indicate to the practised eye the imbecility which is the real cause of the deficient powers of speech. Even for these children something may be done as they grow older by careful teaching; but of course the education of their speaking powers is in such cases only part of the systematic efforts required for the development and strengthening of their intellectual faculties as a whole.

There is yet another class of children who are backward and awkward in their speech, but whose cerebral development is in all other respects complete. These children are bright and intelligent; but it seems as if the power of that part of the brain concerned with speech was ill-developed or latent. Some speak with an exaggerated lisp; others very much like those with cleft palate, having special difficulties with the letters *s* and *l;* while others, again, simply speak like younger children, a child of four talking in the babyish manner of one of two years. All the children of this class feel their difficulty, and avoid speaking as much as possible, making signs and noises rather than facing the trouble of articulate speech. These children all speak eventually quite well, though some slight peculiarity of speech may remain through life. They all improve greatly, and are much helped, by the method of education by imitation which I have described.

Let me just remind you, in passing, of the necessity in all cases of backwardness of speech to ascertain the condition of the hearing. And remember that a child who has even begun to speak may become dumb in consequence of losing its hearing.

Another kind of defective speech is met with in persons with nasal polypi, and in those with adenoid growths in the naso-pharynx. This is recognised by the characteristic want of resonance and the dull "stuffiness" of the voice, this being especially noticed in words involving the sounding of the letters *m*, *n*, or the terminal *ng;* thus "morning" would be sounded "bordig." In these cases the removal of the growths is the obvious treatment. Somewhat similar to this is the thick articulation of persons with enlarged tonsils.

I now pass on to another sort of difficulty of speech—stammering. You all know what I mean by stammering speech. That peculiar spasmodic affection in which the utterance is suddenly checked by the want of coördination of, and control over, the varied movements concerned; so that either the speaker suddenly becomes voiceless, or his efforts result in the rapid repetition of one sound from which he cannot pass on, or in the production of an inarticulate sound of considerable duration, after which come fresh and still ineffectual efforts, or the attempted word is at last pronounced. After this the speech may run smoothly for a time until another spasm occurs. I need hardly tell you that stammering is extremely variable in kind, degree, and frequency of occurrence. But that which is common to all cases is a want of coördination in the muscles concerned. Let me read to you Sir James Paget's description of stammering in his suggestive lecture "On Stammering with other Organs than those of Speech." It gives in bis usual admirable manner the gist of the matter in a few lines:—"Stammering, in whatever organs, appears due to a want of concord between certain muscles that must contract for the expulsion of something, and others that must at the same time relax to permit the thing to be expelled. Ordinary stammerers cannot at the same time regulate the contraction of the muscles of expiration for the proper expulsion of air, and the relaxation of those of the glottis or (in different cases) of the tongue or lips for permitting the expulsion of the air while it is being made vocal and articulate. Numerous as are the varieties and modes of speech-stammering, this discord of muscles is in them all."[2] This gives you the keynote of the difficulty. In some cases it is the muscles of the glottis which are at fault; in others those of respiration; while in another class, and this is by far the most common, it is the muscles of articulation which are insubordinate. Or all these different sets of muscles may be to some extent concerned; and in some very bad cases the spasm may spread to muscles not concerned in speech at all, so that in the efforts at articulation the person is thrown into all sorts of distressing contortions.

Now in the treatment of stammering, it will be necessary to observe in what manner, and under what conditions, it occurs. Some people stammer chiefly or only when they are nervous or in a hurry, or under some excitement, or are fatigued. Others halt only at the sound of certain letters; occasionally, but I do not think often, a sore tongue or mouth will give rise to stammering. I have seen a case also in which its occurrence was quite certainly connected with dyspepsia. Children and young persons are the chief sufferers; and you will find in a large proportion of cases that they come of nervous families, and have been overworked or have in some way been subjected to nervous stress. Thus, intelligent boys anxious to satisfy an exacting schoolmaster, or stupid ones nervous at not being able when called upon to formulate their ideas, or even the impatient, in too much of a hurry to express their rapid thoughts, all furnish us with examples of stammering, which often commences on their first going to school. I have said "boys," because, for some reason which I cannot explain, stammering is much more common in boys than in girls. I ought to mention that in a considerable number of cases it seems to be connected with the habit of masturbation.

In the treatment of stammering, therefore, the first necessity is to discover, and if possible remedy, any obvious cause—especially any cause of nervous debility. And remember that many young people are ill-nourished and dyspeptic from being hurried over their meals; that the same hurried mode of life often leads to irregularity and constipation of the bowels; and that these are also just the people who are apt to be over-studious, too much in-doors, and to lack appetite; often, also, they have bad teeth. So it comes that you will notice many stammerers to be thin, pale, and excitable. For these you will do well to diminish their studies, to enforce out-door recreation and gymnastics, especially such as expand the chest; to attend to their bowels, and to see that they have plenty of nutritious food. And, as in most nervous people, cod-liver oil often does them good. You must also look to the state of the teeth, the tongue, and the digestion, and remedy any defects in these. So, again, any bad habits must be overcome, and the existence of phimosis ascertained and attended to. Iron and other tonics may be useful, and I have certainly seen benefit in cases with other indications of chorea, from the administration of large doses of sulphate of zinc and belladonna. But whatever else you do, you must subject the stammerers to the sort of education which I have described in connexion with some of the other speech defects. That is to say, you must teach them to speak deliberately and with careful enunciation, practising by imitation the difficult words or sounds, and following all the muscular movements of the teacher. Above all, you must teach them to avoid speaking with an empty chest (which, as Charles Kingsley pointed out, is so commonly the habit of stammerers), and to fill their lungs well at every stop. All such treatment will be chiefly useful to those beginning to stammer, and to those whose stammering is variable in degree and frequency of occurrence. But there are some habitual and confirmed stammerers for whom I must confess I know of no cure.

SCHOOL-MADE CHOREA.

A RETROSPECT OF THE PAST YEAR.

By OCTAVIUS STURGES, M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

FOR the last two years, and at this season, I have been permitted to make use of the columns of THE LANCET for the purpose of signalising certain sources of chorea very common amongst the children of our London poor, which by the exercise of a little care and circumspection, less on the part of the poor themselves than of the class set over them, might be altogether done away. There is little new to be said, yet the circumstances may justify some repetition. *Gutta cavat saxum, non vi sed saepe cadendo.* The closing year is not without promise that the public mind is becoming impressed by subjects akin to this. The use and abuse of home lessons, penny dinners, and corporal punishment have been much discussed of late in the interest of school children, and in a calmer and more judicial spirit than that which reigned some while ago when the word "over-pressure" was in everybody's mouth and made two camps.

I know full well that in the long run exaggeration of

Digitized by Google

statement does but defeat its object. Let it be admitted at the outset that St. Vitus's dance is neither a dangerous nor a painful affection with school children, and that such nice adjustment as shall prevent over-strain on the one hand and over-indulgence on the other is practically unattainable; still, it must be insisted that chorea, so long as it remains undiscovered, is a source of injury to the child in many ways, while the obtuseness of observation which so often delays this discovery is nothing short of marvellous. I wish to show in few words—first, that a large and fairly constant proportion of chorea is due directly to what may be called injudicious schooling; secondly, that the chorea which owns this exciting cause may be easily classified both as to its precise modes of origin and as to the temperament of its subjects; and, thirdly, that the rules for preventing chorea in school children are simple and obvious.

During the past year twenty-three cases of chorea (sixteen girls and seven boys) have passed through my ward at Great Ormond-street, not reckoning readmissions, the number being very nearly the same as for the preceding two years. Nine at least have a school cause. For example, a boy of eleven, who some weeks before had been much shaken by a fall, was noticed just before his attack to "bother about his lessons," and "got much caned at school." Another boy of eight, lean and delicate, was "caned at school for some trifling offence. He was much frightened at the time and had restless nights, talking in his sleep about school work." He then developed chorea. A third boy was of the age of twelve. (I take boys by preference, owing to their far less liability to the disorder.) There had been family reverses, and he had fallen with the rest into poverty. "Complaints came from school that his handwriting had deteriorated, and that he was inattentive." It presently appeared that these offences had their origin in chorea. A girl of eleven got her first attack (soon followed by a second) "after a blow on the hand." A child of five, described by her mother "as always excitable," got chorea on being removed to a higher form and having more difficult lessons. A girl of eleven, not very quick, "became irritable in temper during preparation for school examination," and then choreic.

It must be understood that these several statements, and others like them, are put down as "causes" of the chorea that followed only in the absence of any other explanation. No example is included of selection from among several possible causes. And for further proof that such descriptions tend to repeat themselves, and that they fall readily into groups, let me quote from another hospital and a different reporter.[1] In the year 1885, nineteen cases of chorea were admitted into the Westminster Hospital (part only into my own wards). Five at least have a school cause described by the medical registrar in the following terms. A boy of ten was "frightened by being struck at school." A girl of twelve was "kept in after hours every day for a week for bad writing." A girl of thirteen, admitted for a second attack, contracted "the first from hard work at school." A boy of nine (a very severe and prolonged attack) was "excited about school examination just before." Another boy of the same age (also a severe attack), described as "always very nervous," had been much distressed and puzzled with his home lessons, and "would lie awake thinking of sums." The attack of chorea which shortly ensued followed a caning. The two series taken together (i.e., Westminster and Great Ormond-street) give an annual yield of forty-two cases, fourteen of them being of school origin.

The example just quoted reminds me of a child in hospital at the present moment who, like the girl described last year, who "could not get the sums right," affords an excellent specimen of the manner in which the factors are combined that produce chorea. The patient comes from a neighbouring Church school; she is eleven years old, thin and pale, and with a London aspect. There are six others at home as well as the mother, who is a widow and does charing. This child used to help to support the family by going out after school hours to nurse a neighbour's baby. She was so employed sometimes until past eleven at night. Lessons had then to be prepared for the morrow's school, so that it was midnight by the time she got to bed. In the morning she had to wash, dress, and despatch to school two younger children, and thus sometimes reached her own school late, to incur the displeasure of her mistress and occasional punishment. So beset, and being probably ill-fed and by nature weak and delicate, this child contracts chorea in a form which, without being severe, is very intractable.

And even while I write there comes into my ward a small boy, aged fourteen, with very severe chorea, which he has been caned into. He was represented by his parents as "very nervous and unable to sleep without a light." He also suffered much from headache, but had never had rheumatism, nor had his family. At a London School Board school he was charged with speaking to another boy, and for this alleged offence was cut four times across the right hand, one of the strokes catching his thumb and giving acute pain. He came home in a state of high excitement, protesting that the caning was undeserved. The next day chorea seized his right hand and arm, and soon invaded the whole body. The movements are now violent and distressing. He is just able to jerk out a word or two, has wasted much, and is fed with great difficulty.

Speaking from the evidence, not only of the cases I am now quoting, but of very many others precisely similar, it is perfectly certain that for a large proportion of chorea, a proportion that would be under-estimated at one-fourth, school is responsible; and the mode of injury may be classified pretty much as follows:—(1) Over-schooling, where the hours are too long or the lessons (especially *sums*) too hard; (2) excitement in schooling, especially at examination; (3) home lessons where there is no home to speak of or no home leisure; (4) "caning" and other modes of punishment, particularly when unmerited. Such causes will be rendered more or less efficient in individual cases from the feebleness of resistance that comes of insufficient food, natural sensitiveness, previous attacks of the same disorder, tender age or sex. So it goes on from year to year without variety or shadow of change, and but for one reason it would be worse than useless to dwell upon the subject at Christmas time. That reason is, as I have said, that, unlike most of the suffering with which poor London children are over-burdened, it is remediable. There are other sources of chorea besides these: family rows, drunken violence, home cruelty, semi-starvation, the perils of the streets; and we can but total them up at the close of each year and remark upon the wonderful sameness of statistics. But in this school-made chorea it is the friends and would-be helpers of the children, teachers who are responsible for their moral and physical welfare, and anxious to promote both, who are, in fact, active agents in their suffering, and all for want of a little thought.

The evil comes, I am persuaded, from the fact that *teachers do not differentiate their material* in respect of temperament, ability, bodily health, and home circumstances. Their rule of conduct is too rigid and uniform. They might with advantage, and in a literal sense, take a leaf out of the doctor's book, setting down the family and personal history of their pupils just as we do with our patients. Were that done, children would not be put to home lessons which their circumstances make impossible; those that err from disease would not be confounded with those that err from wickedness; and the timid and sensitive would not be struck. Masters tell us that no school can be kept in order without some caning. That may be or not; but it is not the caning that is complained of (although I believe the practice is more common in school and more often injurious than is supposed), it is that they cane the wrong boys, and are not sufficiently alive to the vast difference of temperament, even with near relatives, which makes the very same punishment tolerable, and even salutary, in one case, and detrimental in another. I think it is Marryat who describes two brothers so differently affected by the same incident—parting from home,—that while the one has his handkerchief saturated with tears and is of no further use, the other turns to him with, "Take mine, it's as dry as a bone." Such contrasts are common enough, but there is ample proof that school teachers too often ignore them. What is most to be desired is that those who can speak with authority upon educational questions should concern themselves with this matter of injurious schooling and its nervous consequences. There is at this season, as I have good reason to know, a vast sympathy for poor sick children; it finds expression in many ways, and would be ready to respond to any suggestion for making their lives less miserable. The children I am speaking of should enlist that sympathy to the utmost in their easy forgiveness of the injury that has upset them: cheerfulness under troubles that are apt to make their elders

[1] Report on Chorea, by Dr. Sykes, medical registrar, p. 248, vol. ii., Westminster Hospital Reports.

Digitized by Google

irritable, and persevering, but abortive, efforts to utter words, to handle toys, or to smile their thanks. And if, not a doctor, but some prominent educationist would take up their cause and teach the teachers, the sum total of St. Vitus's dance would soon be sensibly lessened, and no more Christmas jeremiads would be needed on school-made chorea.

Wimpole-street, W.

CASE OF EXTIRPATION OF THE LARYNX WITHOUT PRELIMINARY TRACHEOTOMY.

By JORDAN LLOYD, F.R.C.S., M.B.,
SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

JAMES B——, aged fifty-one, brass-worker, was admitted into the Queen's Hospital, Birmingham, under my care, on Nov. 13th, 1884, having been sent to me by Mr. R. A. Fitch, of Camp Hill Dispensary.

History.—Difficulty of breathing began twelve months ago; stridor also noticed about the same period. No cause assigned for commencement of illness. Cough and expectoration during great part of the time. For three or four months he has had attacks of difficulty of breathing, sometimes very alarming to himself and his friends. Has lost flesh rapidly during the last two months. Has been under treatment at several hospitals. He has worked amongst brass for forty years, and has become so weak and emaciated that he can work no longer. His habits have always been regular and temperate. Had typhoid fever four years ago; no syphilis. No consumption or cancer in his family. Father and mother both died in their seventy-first year.

Present state.—Inspiratory laryngeal stridor and cough; expectoration varying in quantity, never profuse, and occasionally streaked with blood; harsh voice; inability to lie down; paroxysmal attacks of urgent dyspnœa. External examination shows nothing; no enlarged glands. The laryngoscope reveals a cauliflower-like growth of the size of half a walnut springing from the left side of the larynx and below the false cords. No adjacent œdema. Immediately after admission the house-surgeon was summoned hurriedly to him on account of laryngeal spasm to an alarming extent. The difficulty yielded to ether administration. The chest was examined by a medical colleague, and, with the exception of a few bronchial râles, was pronounced to be quite healthy. The man's condition was so distressing that he was eager to have anything done which would relieve him, and on Nov. 22nd I performed the following operation.

Operation.—Chloroform was given on a towel as he sat upright in bed; he was then carried to the operating theatre, and laid on the table. A three-inch median incision was made, with its centre opposite the middle of the thyroid cartilage, and extending at once down to the walls of the larynx. The exposed thyroid isthmus was tied with two ligatures, and divided between. All structures were now freed from both sides of the larynx with scissors, without opening its cavity. There was no trouble with the bleeding or with the breathing. A loop of stout wire was passed through the top of the thyroid cartilage to enable the operator to have full control over the larynx. The patient was then drawn up the table so as to allow his head to hang pendent over the end. The trachea was next divided just below the cricoid cartilage with Paquelin's cautery, and no bleeding took place. Into the cut trachea the end of a large curved glass tube, very much like an old-fashioned vaginal syringe, about five-eighths of an inch in diameter and eight inches long, was introduced for about two inches, completely filling the air-tube. This arrangement prevented blood from entering the trachea, and enabled the anæsthetiser to administer chloroform without interfering with subsequent manipulations. The thyroid cartilage was next split in the middle line, and the lateral halves rapidly removed with scissors. The cricoid was cut out, also with scissors, in a single piece. Bleeding was not severe. The blood flowed into the dependent part of the wound (pharynx and nares), scarcely a spot being drawn past the glass tube up into the air-passages. The superior laryngeal were the only vessels requiring ligature. The trachea was sutured to the skin at the lower angle of the wound, and a large-sized tracheotomy tube substituted for that of glass. The operation lasted about forty minutes. The patient was put in a covered bed, and ordered to be fed on nutrient enemata every three hours. When seen at night he had completely recovered from a slight amount of shock, and was breathing quietly, and wrote on a slate that he was quite comfortable.

Nov. 23rd.—Slept several hours during the night. Retains enemata. Was fed with an elastic tube into the stomach this morning.

24th.—Cough, restlessness, coarse râles and rhonchi over both lungs. Broncho-pneumonia set in, and, gradually increasing, he died on the 28th, six days after the operation.

Examination of the larynx showed a large intra-laryngeal outgrowth on the left side, probably of tubercular origin, and the necropsy revealed a condition of purulent bronchitis extending into the smallest bronchioles, infundibula, and pulmonary acini. Both lungs were everywhere studded with small miliary tubercles. There was no cellulitis about the wound.

Remarks.—I am led to publish the above as an additional case to those referred to at the meeting of the Clinical Society, held on Nov. 12th. I think it is interesting from the fact that no preliminary tracheotomy was performed, the course of proceedings above practised rendering it unnecessary. The larynx was freed from all lateral attachments before the air-tube was opened. The trachea was cut across with the cautery and plugged with a large bent glass tube. The patient's head hung over the end of the table, and allowed all blood &c. to escape from the lungs rather than into them. The removal with scissors expedited the operation and reduced the blood loss to a minimum. The broncho-pneumonia would have followed any other method of procedure. The case was originally thought to be one of laryngeal epithelioma; it presented all the signs of this condition, and the report on the state of the lungs supported this diagnosis. The operation of extirpation of the larynx I regard as a serious surgical experiment, and whether it will ultimately establish itself as a surgical desideratum in any case, time and further experience alone will enable us to decide.

Birmingham.

CASE OF GASTROSTOMY WITH TRACHEOTOMY FOR CANCER OF THE ŒSOPHAGUS AND LARYNX.

By JOHN PENNEFATHER RYAN, L.R.C.S.I., &c.

As a means of prolonging life in impassable stricture of the œsophagus the operation of gastrostomy had up to 1872 been performed (according to "Gross's Surgery," published in that year, only ten times—twice each by Sédillot, Forster, and Sydney Jones, and once by Fenger, Curling, Durham, and Maury. In none of these cases was the result encouraging, as all the patients died within a short time after operation, either from exhaustion or peritonitis. Since 1872 I am aware that there have been several cases in which life has been prolonged for some months occurring in the practice of Mr. Bryant and other surgeons, but of these I possess no record to which I can readily refer. In Gant's work on Surgery (1878), the most recent I possess, the author states, in writing of the operation (vol. ii., p. 368), that "it has hitherto always proved rapidly fatal." Possessing this meagre and not very encouraging information, it was with great reluctance that I recently undertook the operation, and then only at the urgent request of the patient (an elderly lady) and her near relatives.

Mrs. L——, aged sixty-one, a lady in good circumstances, first consulted me at the beginning of 1885 for a difficulty in swallowing, which was gradually increasing, and attributed by her to "spasm of the gullet." It was now impossible to swallow solid food, and liquids slowly and with considerable difficulty. Having made a careful examination and failed in passing even a small-sized catheter, I diagnosed a tumour of, or pressing on, the œsophagus, probably malignant, but possibly fibrous. Some weeks afterwards I again saw the case in consultation with my friend, Dr. Power of Brisbane, who concurred with the view I had taken, and we then discussed the propriety of an operation, but decided against it on the supposition that the disease was of a malignant nature. No hope of ultimate recovery

Digitized by Google

being held out to the relatives, they consulted a German homœopath, who, although not understanding the case, said he could cure it. Having failed, an equally sanguine alopath undertook the cure, so that for several months I heard but little of the progress of events. On Oct. 24th Dr. Power, who had come to help me at an ovariotomy, again saw the patient, who was in an extreme state of emaciation and debility, not having been able to swallow even one drop of liquid for more than a week, life being sustained entirely by nutrient enemata. Dr. Power suggested a gastrostomy, and advised the friends to ask me to operate. I consented, and on the 26th, assisted by Dr. Power and Dr. Small (now practising in Geelong), performed the operation. The condition of the patient was one of extreme distress, as not only had emaciation advanced to the last degree, but respiration was rendered extremely difficult by pressure on, or invasion of, the larynx by the growth. Thirty minims of æther. sulph. having been injected hypodermically as a precaution against syncope, chloroform was administered, and, as the breathing became easier under its influence, it was decided to proceed with the gastrostomy without tracheotomy. The incision was what is known as the oblique, commencing about an inch below and to the left side of the tip of the ensiform cartilage, and extending downwards and outwards parallel to the border of the costal cartilages, about two inches distant from them. The peritoneum being reached was hooked upon a tenaculum, and then divided on a director with a suitably shaped scissors. The left edge of the liver being exposed, a finger was passed along it, and the stomach felt and seized with an ordinary polypus forceps; it was drawn into the wound and firmly held while it was carefully stitched with silver wire to the edges of the incision, care being taken to include the parietal peritoneum in each suture, the lowest of which was passed about half an inch below the inferior angle of the wound, thus effectually preventing any downward leak into the peritoneal cavity. At this stage of the operation, the heart's action becoming weak, a second hypodermic injection of ether was administered, with an immediately beneficial effect. As death seemed imminent from starvation, it was determined to open the stomach at once, which was accordingly done in the manner recommended by Mr. Fagan.[1] A narrow sharp bistoury was passed obliquely into the stomach, and along it a probe bent at a right angle about an inch from the point; the knife being then withdrawn, another probe similarly bent was introduced, and the two being gently pulled in opposite directions at right angles to the muscular fibres of the viscus, a No. 9 catheter was introduced, and the operation thus completed. During the entire proceeding little blood was lost, no vessel requiring ligature or torsion. At first it appeared as if the incision in the stomach would bleed freely, but it soon ceased, and was never alarming. A glass syringe, deprived of its piston, was now introduced as a funnel into the catheter, and about four ounces of warm milk allowed to gravitate into the stomach in this way effectually guarding against regurgitation, care being also taken to mop up with absorbent wool the few drops which escaped when the catheter was withdrawn. I may say that this plan of feeding was rigidly adhered to until union was firm and complete. The wound was dressed with soft absorbent wool, and a pad of the same applied over and secured by a flannel bandage. After the third dressing a piece of lint freely smeared with vaseline was applied directly to the wound, pad, and bandage as before. On recovering consciousness the patient complained of acute pain at the seat of operation. This was soon stopped by twenty drops of laudanum given with the usual nutrient enema. As it seemed advisable not to tax the stomach at first, the nutrient enemata were continued at intervals of six hours, and only warm milk in gradually increasing quantities, given by the stomach, till on the fourth day a pint and a half was thus taken, and the same quantity on the fifth, after which beef peptonoids were mixed with the milk, and other articles of diet, such as beef-tea, eggs, &c., allowed. For three days it was necessary to use the probes in the manner before described, in order that the catheter might be passed; but after that it was introduced with comparative ease, though at no time did any but slight regurgitation occur. On the fourth day the enemata were finally discontinued, the patient expressing herself as feeling stronger and experiencing a comforting sensation after being fed. The dyspnœa, however, which at first seemed much relieved, was gradually increasing, and on Sunday, Nov. 1st, its urgency compelled me to perform tracheotomy, which gave immediate relief. On the twelfth day I removed all the sutures (eight securing the stomach and two uniting the upper part of the abdominal wound), as union was then perfect and firm.

During the progress of the case there had been no symptom of peritonitis, nor since the first few hours had there been any pain. The patient was gaining flesh rapidly, and was able to sit up in bed. It would now have taken some force to dislodge her wedding-ring, which before the first operation was constantly falling off the shrivelled finger which had worn it for about forty years. On the seventeenth day she was able to walk from the bedroom to the dining-room and was improving rapidly in every respect. She expressed herself (on slate) as feeling perfectly comfortable and at rest. It was now reasonable to suppose that life might be prolonged for some time to come. In any case the two operations seemed justified by the result up to date, and my only regret is that both were not performed earlier, my excuse for not doing so being that, owing to circumstances before mentioned, I lost sight of the case for more than six months. The pulse was now 80, the tongue clean and moist and otherwise normal in appearance, although before the tracheotomy it most resembled a piece of petrified raw beef. To the admirable paper by Mr. Fagan, F.R.C.S.I., surgeon to the Royal Hospital, Belfast,[2] I am indebted for the useful practical hints as to the incision and the mode of opening the stomach. To the careful and intelligent nursing by her daughters, and to the wonderful vitality and pluck of my patient, the success of both operations must in great measure be ascribed.

The foregoing notes were written on the seventeenth day after the operation, and express all I then knew of gastrostomy and its statistics. Since then I have naturally taken some interest in acquiring all the information attainable on the subject, which I have found condensed in THE LANCET of Dec. 5th, 1885, in the report of a discussion at the London Clinical Society on Nov. 27th. I will merely quote the remarks made at this meeting by Mr. B. Jessett, and then proceed to give a short account of my case from the seventeenth day to June 5th, 1886, when death took place, seven months and eleven days after the gastrostomy, which was followed by tracheotomy on the sixth day.

"Mr. B. Jessett asked the question whether gastrostomy was justifiable. He thought, as the result of examination of several series of statistics, that it was not. Gross of Philadelphia had collected 167 cases, and 117 died within one month. Mr. Jessett had collected sixty cases of œsophageal cancer; in thirty-five gastrostomy had been performed, the average duration of life after operation was twenty-six days, and the longest duration was five months. This was the case that Mr. Charles Stonham had shown before the Clinical Society last session."

My patient quickly regained flesh and strength, and for more than five months her second life was free from pain and as enjoyable as possible, considering the artificial means which had been adopted to secure it. The swelling in the throat slowly but surely increased, until it became too evident that the larynx and trachea were extensively invaded by the disease. About the beginning of the sixth month distressing and frequent attacks of spasmodic dyspnœa occurred. These were greatly relieved by steam inhalations medicated with chloroform and hyoscyamus, to which, after a while, was added acid. hydrocyanic. dil. (two or three drops in each inhalation), with excellent effect. There was little or no pain until about a fortnight before death, when she was allowed to take occasional doses of laudanum, with, however, but little relief. During the latter two months hæmorrhage occurred on several occasions from the tracheal wound, and once in alarming quantity from the mouth and nose. Towards the end she took but little food, as it seemed to cause "pain in the chest." There was no fetor from the expectorated matter or saliva, both of which were considerable.

The post-mortem examination, made six hours after death, revealed a cancerous mass extending from the spine forwards, completely obliterating every trace of the œsophagus for several inches, and involving the larynx and trachea to such a degree that the tube was embedded in the neoplasm, which had also extensively infiltrated the skin and

[1] British Medical Journal, Oct. 4th, 1884.

[2] Ibid.

Digitized by Google

other tissues in front. The stomach was firmly adherent to the abdominal wall, in which was seen the small fistulous opening through which life had been solely sustained for more than seven months.

At the Clinical Society of London, on Nov. 27th last, Mr. Barwell read notes of a very similar case, in which a gastrostomy performed on April 25th was followed by a tracheotomy on July 21st, the patient surviving the former operation nearly five months, and the latter nearly two. The necropsy demonstrated the existence of a cancerous mass which "extended back to the spine, and all but filled the œsophagus from a little below the cricoid cartilage to a level with the tracheal bifurcation; it had also grown into the trachea opposite the fourth cervical vertebra." Dr. T. F. Chavasse of Birmingham, in an excellent clinical lecture on Gastrostomy for Œsophageal Cancer,[3] reports a case where the patient survived the operation nearly six months. In this case the obstruction was six inches from the upper dental arch, but not impassable, as on Dec. 7th, more than four months after the operation, we read "the patient's swallowing has much improved, and now nourishment passes freely into the stomach after 'sticking a bit.'" There is no account of the necropsy. Comparing these cases with Mr. Dent's (the notes of which were read on the same occasion as Mr. Barwell's), it seems to me that the higher the seat of disease the better is the chance of prolonging life by operation, and this consideration should greatly influence the surgeon when deciding whether to operate or leave nature to take its course. The operation is neither a very difficult one nor nearly so trying to the pluck and resources of the surgeon as an average ovariotomy. The incision should be kept well away from the costal cartilages, or trouble will be caused by retraction of the upper flap. The stomach should be seized above the lower border of the great curve and drawn into the wound in such a way that the point of seizure may be that at which the final opening is made. It is of importance that a considerable area (say about the size of a five-shilling piece or larger, though of course not the same shape) of stomach should be within the ring of sutures in order to allow for subsequent contraction, which is considerable and rapid (in my case at the end of three weeks the portion exposed was not the size of a sixpence), and to permit of firm stitching. The opening should be a narrow slit made as described. Only small quantities of food (milk) should be given by the stomach and at considerable intervals (say six or eight hours) for several days, during which time the nutrient enemata must be continued. Any regurgitation must be instantly mopped up with absorbent wool laid round the opening where the catheter is introduced. Until union is firm and complete the milk should not be forced into the stomach, but allowed to gravitate in a manner like that which I adopted.

Gympie, Queensland.

A CASE OF

APHASIA FOLLOWING A DEPRESSED FRACTURE OF THE LEFT SIDE OF THE HEAD.

BY GEORGE R. TURNER, F.R.C.S.,
VISITING SURGEON TO THE SEAMEN'S HOSPITAL, GREENWICH.

ALEXANDER F——, aged twenty, was admitted into the Seamen's Hospital, Greenwich, on June 7th, 1883. He was in a drowsy, sleepy condition, requiring to be roused and shouted at before he would answer, and then did not apparently understand what was said to him. To every question asked he answered, "No," and this was the only word he could articulate. There was a granulating scalp wound in the left parietal region, which was nearly healed. Around this, to the extent shown in Figs. 1 and 2, was a depression of the subjacent bone. At the fore and upper part of the margin of this there was some little elevation, which made the neighbouring depression appear deeper than it really was. The whole depression was bowl-like; it had a curved lower border, extending from some two inches behind the external angular process upwards and backwards nearly to the sagittal suture, an inch or more above the summit of the occiput. The greatest depression was perhaps less than half an inch. The patient lay in bed on his side, curled up, with the legs flexed on the thighs and the thighs flexed on the abdomen. The pupils were equal, and responded to light; the bowels constipated; the pulse slow. The scalp-wound rapidly healed, and he became more intelligent. It was then found that he was deaf on the affected side, and that there was some slight loss of

FIG. 1.

grasping power on the right side; otherwise there was no evident paralysis.

The correct history of the case could not be obtained at the time of the patient's admission. Except that the injury was three weeks old, and that he had been in a hospital at Flushing, nothing could be ascertained. The Flushing authorities, on being written to, reported that he was admitted in a state of unconsciousness, but recovered his senses and power of speech in a few days, though only for a

FIG. 2.

while, as he remained in a state of heaviness till he left, eighteen days after the accident and four days before admission into the Seamen's Hospital. This report, given only from memory, as no written notes were taken, differs somewhat from the account subsequently obtained from the man. The injury was inflicted by a windlass striking his head during a gale at sea.

In a week or ten days after his admission into the hospital he could say the word "yes," and used both it and the negative appropriately. In a month or so his il-

[3] THE LANCET, Feb. 20th, 1886.

telligence appeared to be perfect or nearly so, though he could still say but few words. He collected some money and bought himself some boots, explaining to me by signs what he wanted to do. On my telling him that I wanted him photographed he at first objected, and when I asked him if he understood me he replied by putting himself into an attitude as if he were being taken, and imitated the camera. About this time, on being told to write, he made "pothooks" and "hangers." After this came a time when he wrote "yes" and "no" (the first words he could say), sometimes misplacing letters or running the words into each other. He could play draughts and dominoes, and corrected the mistakes of other players. His use of words gradually increased. He required teaching like a child to pronounce them distinctly, and sometimes misplaced them—saying, for example, "scissors" instead of "sister." He could soon write words that he could not speak or apparently remember—e.g., his name and birthplace. He was very emphatic in his utterance and annoyed at his mistakes. There was a want of grammar in the construction of his sentences, and he used only the important words. At first he was unable to count more than "one" and "two." On being taught, he acquired this with facility, but could not say "seven," "eleven," or "fifteen." He got over his difficulty by saying "six one," "ten one," "ten five." Occasionally in counting he put the numerals in the wrong order, but was aware of and annoyed at his mistake. When he saw figures written, he knew what they meant; for instance, on one occasion he told the sister that I was in "ten five" ward. He could read, and understand what he could not say. One day, whilst out of the hospital, he was given some port wine, which "got to his head." On being asked what he had had, he went to a notice, "that no wine, beer, spirit, or porter, &c., was allowed to the patients without permission," and covered up the last syllable of porter. He was easily taught to say the word, and could repeat it after one. It was about this time (Oct. 26th, 1883) that I showed him as a living specimen at the Clinical Society. Mr. Adams Frost was kind enough to examine his eyes, and reported as follows: "As far as I can ascertain, your patient's vision is $\frac{6}{6}$ in each eye. The visual field is good in each, and the ophthalmoscopic appearances are normal." Sir William Dalby kindly examined him as to his deafness on the left side, and reported that its cause was central, "such as you meet with in concussion." He had an attack of scarlet fever, and was in the Fever Hospital, Stockwell, from Nov. 9th, 1883, to Jan. 16th, 1884. His aphasia slightly improved during this time. On his return he used to make himself useful about the hospital. He was often sent by the patients outside the hospital to buy tobacco, and was perfectly well aware of the value of money; as proof of this, it may be mentioned that he found a post-office order in one of the corridors and brought it to the house-surgeon.

March, 1884.—Shown a shilling, he calls it a "bob"; writes the word "shilling," but is incapable of pronouncing it. When words are repeated to him with a view of teaching him, there seems to be actual inability to regulate the requisite movements of the vocal muscles for articulation. (This was occasionally the case in November, 1885.) Learns new words imperfectly, and on returning to them after an interval the same process has to be repeated. (In Nov. 1885 there was great improvement in this particular.) When told to copy two verses of a song in which such words as "fascinating," "misfortune," "consequently," and "panorama" occurred, he did so with the exception of two mistakes, which he was afterwards able to correct. He cannot repeat the alphabet beyond *f*. When letters of the alphabet were placed in order, he could repeat and give their names, with the exception of *h*, *l*, *m*, and *z*, and it was found that he was incapable of pronouncing any word in which any of these letters formed a prominent element. (His condition was the same in November, 1885, but he could pronounce words containing these letters better.) When letters were placed before him indiscriminately he could only pick them out in order up to *g*, but knew the names of several others. (Nov. 1885: He can now pick them all out, and name them all, except *h*, *l*, *m*, and *z*.) Can count up to "ten," with the exception of "seven." (Nov. 1885: Can count up to "one hundred.") He can do a simple sum in addition, but has some little difficulty when he has to carry a number. (Nov. 1885: Just the same.)

November, 1885.—His memory appears now to be quite natural, whereas about a year ago he could give no details as to his early history, the accident, or admission into the hospital. He says now he ran away to sea on account of ill treatment from an aunt at home, and gives details of this. He is able to give a clear account of his accident: that a heavy sea came overboard, washed a companion away, and took him off his legs; that he was whirled round by the winch until the handle broke. He has no memory of Flushing, but remembers coming to Greenwich on board ship; vomiting after taking tea, &c.; being carried from the river to the Seamen's Hospital by the captain, mate, and two other men; his reception at the hospital by a gentleman whose person he accurately describes, and who, it happened, was doing house-surgeon's duty for the day; he remembers also being asked his name by Mr. Johnson Smith, and being unable to answer, although he knew it perfectly. He still uses a few signs and occasionally comes across words which he can write down but cannot say—e.g., "*Village Belle*" (the name of his ship), "knife," "blotter." When told to spell the latter word, he spelt "biotter," yet wrote it down "blotter." Is able to name common objects about the room. His vocabulary is altogether more extensive. His left hand is now his best; formerly he was right-handed. Writes from dictation and copies much better than he did. In copying, he looks at the words and writes them straight off. He does not copy each letter. He can hear every note in the chromatic scale, and can sing every note within his compass which ranges from C below the treble stave to F on the fifth line. He can sing several airs—such, for instance, as the favourite tunes he has learned from hearing them sung in the streets. He has a tolerably good ear for music.

Present condition.—There is still paresis of the muscles of the right upper extremity, lower part of right side of face, and right side of tongue. The ring finger of the right hand is also colder than the other fingers. Since he left the hospital some months ago his speech does not appear to have improved. Mr. Victor Horsley was kind enough to examine the patient for me, and satisfied himself that "pressure is still exerted on the centres for speech, face, and arm." The point of severest pressure (just under the overhanging edge of the upper border of the bowl-like depression) is in the ascending frontal convolution nearly at the point of junction of the face and speech centres. The lower border of the depression follows the Sylvian fissure as nearly as possible.

FIG. 3.

x shows the point of greatest pressure.

This case was no doubt originally one of compound depressed fracture of the skull. When the patient was admitted into the Seamen's Hospital the aphasic condition was not at once recognised; he seemed to be in a state of slight cerebral irritation and semi-drowsiness, and this for a short time masked the aphasia and paresis of the right upper limb. Any want of intelligence or consciousness of what was passing around him was more apparent than real, as proved by his subsequent accurate description of the details of his admission. He began very soon to regain his speaking power. The depression of the skull was not very deep, and extended over so large an area that trephining did not seem to be urgently indicated as long as he continued to improve. (See Fig. 3.) The patient, too, has throughout been adverse to any operation, and it was three weeks after the accident that I first saw the case. Now that he is no

Digitized by Google

longer taught to speak new words his condition remains the same, and all improvement seems to have ceased. He still, however, refuses operation.

I have been able to obtain the following cases of aphasia resulting from injury. The case of Mr. Jalland and that of Surgeon Basu most nearly resemble mine:—H. Campbell Pope, M.D., and Rickman Godlee, M.S.: "A case of punctured wound of the left orbit, followed by aphasia; recovery." (THE LANCET, June 19th, 1886.) Professor Fraser: "Aphasia from injury; subsequent hemiplegia; trephining; death; necropsy." (THE LANCET, Feb. 27th, 1886.) Mr. Morgan: "Compound depressed fracture of skull, with loss of cerebral substance; aphasia." (*British Medical Journal*, vol. i. 1885, p. 1155.) Mr. Verrall: "Aphasia after injury." Read at the Brighton and Sussex Medico-Chirurgical Society. (*British Medical Journal*, Sept. 1884.) Kast: "Aphasia, with loss of ear for music." (Mentioned in THE LANCET of Nov. 6th, 1886, p. 878.) Basu: "Compound depressed fracture of skull; aphasia; right hemiplegia." (*Indian Medical Gazette*, Calcutta, 1880, vol. xv., p. 99.) Mr. Jalland: "Compound fracture of skull; elevation; aphasia." (*British Medical Journal*, vol. ii. 1881, p. 706.) Rex: "Fracture of skull; hernia cerebri; aphasia; hemiplegia" (Oregon Medical Society, Portland, 1882, vol. ix., p. 40.) Lloyd: "Compound depressed fracture of skull; eight square inches of bone removed; wound of longitudinal sinus; secondary aphasia; embolic pneumonia; complete recovery." (THE LANCET, vol. ii. 1885, p. 892.)

Mr. Verrall's case was one of several attacks of aphasia, lasting for twenty-four hours and upwards, following a blow on the occiput. There was some slight right hemiplegia. Complete recovery took place in five weeks' time.

The case of Mr. Morgan of Sunderland was one of aphasia following a compound depressed fracture of the left parietal bone, in which elevation was practised. A wound of the superior longitudinal sinus occurred, and hernia cerebri followed. The aphasia came on thirteen days after the operation, and was permanent. There was also permanent right hemiplegia.

In Professor Fraser's case, although the aphasia followed a blow on the left side of the forehead, it was found on post-mortem examination to be due to a glioma involving the temporo-sphenoidal lobe and Broca's convolution.

In Mr. Jalland's case there was a compound comminuted depressed fracture a little above the left ear and temple; dura mater uninjured. Elevation of depressed portion of bone was practised. Subsequent aphasia was discovered on the patient recovering consciousness; slight left facial paralysis; deafness for ten days; unable to repeat from memory; broke down at fifth letter of alphabet, fourth word of Lord's Prayer, &c.; could not write from dictation, &c. Recovered completely in all respects in less than two months. This case more closely resembles the one I have related than any of the others.

In Mr. Lloyd's case the patient was conscious, but could not speak, Broca's convolutions being compressed by blood-clot, which was subsequently removed. There was an almost complete disappearance the following morning of the hemiplegia and aphasia, pointing to absence of gross lesion of the brain tissue itself. These symptoms returned, however, on the fourth day, and subsequently somewhat rapidly disappeared.

Surgeon Basu's case was that of a Hindoo struck on the head with a "lathi." Insensible for two days. Right upper limb completely paralysed. On recovering his senses he was found to be aphasic, answering "Yaam" to all questions. He understood fairly, and expressed his desires by hints and gestures. He had a contused wound in front of, and internal to, the left parietal protuberance; at the bottom of this was a depressed fracture of the skull, said to be one-fifth of an inch deep. The aphasia got well first, and then the paralysis of the arm. It should have been mentioned that on admission his tongue pointed to the left when protruded.

Dr. Charlton Bastian, who saw my case at the Clinical Society, kindly showed me a photograph of a man who had a depression on the right side of his head. "This man was not aphasic at all, though he was partially hemiplegic on the left, and subject to unilateral convulsions on this side; the depression in his case was more uniform, and, I think, a trifle deeper than in yours." The above is an extract from a letter of Dr. Bastian to me.

THE SURGICAL TREATMENT OF ACUTE ABDOMINAL DISEASE.

BY WILLIAM COATES, M.R.C.S. ENG., L.R.C.P. ED.

THE contributions that have recently appeared in THE LANCET on the above subject are full of interest and information, especially those by Mr. Lawson Tait and Dr. Wade, which must engage the particular attention of the profession. As it is suggested that some diseases which have hitherto been left to the resources of medicine can be more successfully treated by the surgeon, it is clearly a duty that any case which bears at all upon the subject should be placed upon record. Such being so, perhaps the narrative of the following two cases may be considered worthy of perusal.

CASE 1.[1]—*Perforation of a small stone through the vermiform appendix, followed by acute fæcal abscess and general peritonitis; operation; death.*—H. F——, aged eighteen, a young woman, came under observation on Jan. 11th. She was a member of a healthy family, and had never been seriously ill. Five days before coming under my care, whilst in service, she was suddenly seized with acute general abdominal pains, which were the most severe on the right side, and continued for about six hours. She was free from pain and slept well during the night, and, though feeling a little soreness, resumed her duties on the following morning. During the afternoon the pain returned in the right side of the abdomen; it gradually spread all over the bowels, which became constipated, and she began to vomit. Purgatives were administered, but, becoming worse day by day, she was sent home in a cab, a distance of several miles. When first seen on the evening of the above date she was exhausted after the journey and very ill. Her face was pinched and expression anxious; tongue dry and furred; temperature 103°; pulse 130, small, quick, and thready; chest healthy; knees drawn up; and she complained of acute abdominal pain and vomiting. The abdomen was distended, tympanitic, and painful. The pain was severest in the cæcal region, but no swelling or resistance was detected. The rectum, loaded with fæces, was relieved by simple enema, opium administered, and poultices locally employed. On the 12th her condition was unaltered. On the 13th there was abdominal distension, and the pain on pressure over the cæcal region and the general signs of peritonitis were decidedly increased. On the 14th the temperature was 103·2°, the pulse 120, and the vomiting and abdominal pain more severe. There was a decided sense of deep-seated resistance in the cæcal region, where pressure produced much pain. No swelling could be felt per rectum. There was retention of urine. On the 15th the temperature remained high, the pulse rapid and small, and the vomiting was exhausting her. The abdomen was more distended, and in the cæcal region, covered by tympanitic bowel, in a position where pressure was most resisted, an obscure swelling could be felt. Under chloroform the swelling was more defined, apparently deep seated in the iliac region. It could not be felt per vaginam. On introducing the aspirating cannula into the swelling a few drops of offensive pus oozed out, but nothing was drawn into the aspirator. An exploratory incision about three inches in length was made, beginning a quarter of an inch above the middle of Poupart's ligament and extending obliquely upwards and outwards above the anterior iliac spine, and a dissection made upon the swelling. Out of it about five ounces of offensive fæcal pus were evacuated. On introducing a finger, it entered into a large irregular cavity around the cæcum, from which a small stone about a quarter of an inch in length was removed. This was oval in shape, and composed of fæcal matter arranged in a laminated manner, and surrounded by a hard, dense phosphatic layer. There was a small opening into the peritoneal cavity, which possibly was made during the dissection upon the swelling. As no post-mortem examination was allowed, the exact condition was never determined, but the distended bowel immediately over the swelling appeared to greatly increase the risks of wounding the peritoneum. The patient's condition appeared too critical to permit any extension of the operation, so the cavity was washed out with carbolic solution, drainage-tubes intro-

[1] This case was mentioned before the Manchester Medical Society on Feb. 3rd.

Digitized by Google

duced, and the wound dressed. After the operation the patient rallied, her symptoms having been decidedly relieved; but after a time the vomiting returned, and she gradually sank, dying in twenty-four hours.

CASE 2. *Obscure abdominal symptoms and death, caused by localised enteritis set up by a fish-bone.*—M. W——, aged seventy-one, the subject of chronic bronchitis, was as well as usual until Feb. 5th, when she complained of indefinite pains. These becoming worse, she was first seen on the 7th. Defective articulation made it difficult for her to describe her symptoms; but she was suffering from pains in the abdomen, which region, however, was neither distended nor very tender. The temperature was 98·4°, the pulse 100, and the tongue a little furred. A calomel purge, sedative mixture, and hot fomentations were employed. On the following day the bowels were relieved, but there was slight abdominal distension, with some tenderness. The temperature was normal, but the pulse was 110. On the 9th the abdomen was more painful, vomiting set in, and she died rather suddenly, probably from syncope, ninety hours after the first onset of symptoms. On opening the abdomen post mortem, a discoloured portion of bowel eight inches in length was found at the junction of the jejunum and ileum. The central four inches of this were acutely inflamed and somewhat indurated, but not at all gangrenous. The sharp end of a small fish-bone (¾ in.) was projecting through the wall of the bowel into the peritoneal cavity, and this had originated the mischief. The large intestine was occupied by hard fæces, and in the descending colon a large fish-bone (2½ in.) was discovered travelling safely. The small intestine contained a large quantity of a chymous fluid, which looked very much like pus, but under the microscope it showed vegetable débris—starch granules and stray phosphates. There was no fluid or lymph in the peritoneal cavity, nor other sign of peritonitis, except slight hyperæmia in the immediate neighbourhood of the inflammation.

The age of this patient and the existence of subacute bronchitis precluded the advisability of resorting to operation; but if in a similar case in a younger subject an exploratory operation were performed, the foreign body irritating the bowel might readily be detected and removed, the bowel itself dealt with, and a chance of recovery afforded. It is interesting to note that the fish-bones had escaped digestion, and that the larger bone was travelling safely in the midst of a mass of faces, whereas the smaller one, happening to be in a portion of the bowels where the contents were fluid, was arrested by contact with the wall of the bowel, exciting local inflammation in and penetrating through it. This fact favours the administration of astringent rather than purgative medicines after the accidental swallowing of foreign bodies.

Referring to Case 1, it is reasonable to suppose that, had its nature been clearly recognised at an early stage, before the occurrence of acute peritonitis, an operation such as the one performed might have been accomplished without further injury to the peritoneum, and with a fair prospect of success; or even at the later stage, when first she came under my care, before the iliac swelling was detected, if the abdomen had been boldly opened, the pus might have been evacuated, the abdomen thoroughly cleansed, free drainage established, and recovery hopefully looked for. But, on the other hand, what would have happened had the surgical treatment been left alone? Could not life have been sustained long enough by nutrient enemata &c. until the near approach of the abscess to the surface allowed a safe incision? Cases of perityphlitis are readily recalled to mind where, after patient waiting, the swelling has made its way to the surface, and a simple incision has ended in recovery. But in these cases the peritoneal complication is usually of a milder type, and so they compare unfairly with the above.

The treatment of acute abdominal disease, now that surgery claims a part in it, is surrounded by difficulties, especially to the general practitioner. The consequence of an unsuccessful operation to him is of much importance; but still no operation must be shirked which promises to relieve suffering and prolong life, and still more should he avoid operation where such is not necessary to recovery. Modern surgery lessens the risks of these great operations, but how must the cases be decided in which it is justifiable to perform them? If an operation be delayed until after the failure of medicine the prospects of successful surgical interference are greatly minimised, whereas if a much larger proportion of the cases are treated surgically many will have to submit to an operation which would have recovered without. Every week cases of acute abdominal disease come under notice—some mild, others most severe,—and the larger proportion by far recover. Even the most violent case is not without hope. That being so, the responsibility of advising an exploratory operation is indeed very great, and the practitioner at present looks in vain for some standard rules to guide him. More accurate and detailed observation of the course and symptoms of these diseases, and the cultivation of the art of more minute diagnosis, must eventually make it possible to differentiate between those cases which will yield to medicine alone and those which demand the assistance of surgery. Meanwhile, it might be a good rule for guidance to imagine ourselves to be the patient, and to operate accordingly. It is hoped that the above cases may be of use to those who are working at the subject.

Manchester.

NOTES ON

ENTERIC AND TYPHO-MALARIAL FEVER.

BY SURGEON-MAJOR H. JAGOE, M.S.

THE discussion at the Medical and Chirurgical Society on enteric fever at Suakim, reported in THE LANCET of Feb. 13th, 1886, induces me to forward this communication, with the hope that it may prove interesting.

The cases and necropsies which I give are from notes taken in Zululand, Afghanistan, and India, and the temperature charts attached to elucidate the cases are two out of a very large number that I took to try to clear up the distinction between enteric and what is called typho-malarial fever. I agree with Dr. Squire that the large majority are as clear and distinct cases of enteric fever as those seen in this country, but I doubt very much the advantage of the term "typho-malarial" to express a fever which, to my thinking, is far more fairly expressed by the name "bilious-remittent." As Dr. Broadbent stated, there is nothing typhoid about it, "nothing in common with enteric fever, if we except the fact of a protracted high fever with some intermissions." There is a protracted fever of about forty-six days, with an interval of eleven days, during which there is a total absence of any rise of temperature; or in its course there may be two intermissions. It has been suggested that these are mild cases of typhoid with relapses, but there is not a single symptom of enteric fever about them; on the contrary, they seem to be more of a bilious-remittent type. There is frequently yellow tinging of the skin and conjunctivæ, often vomiting, and the tongue pale, clean, sometimes coated with a yellow fur, and frequently large and indented by the teeth; at no time is there any degree of the red irritable, and contracted tongue of enteric fever, or any other mild characteristic symptom of the disease. These are the class of cases that I understand it is proposed to call, or have been called, "typho-malarial." I have never seen a death caused by them, if I except one patient who died during the last march into Candahar on Sept. 18th, 1879. Chart 1 shows the last nine days of the fever; the previous eight days had been spent under the care of the regimental surgeon. The patient was very much in the condition described above when admitted into the field hospital. There was diarrhœa; the upper surfaces of the conjunctivæ were slightly jaundiced; there had been some vomiting; and the pulse was small and weak (about 86); the tongue was moist, large, and indented by the teeth. The man was perfectly sensible and intelligent up to half an hour before his death. In Candahar I could only make a very hurried necropsy, but I found the lower part of the ileum perfectly healthy, not even congested; the liver and spleen were enlarged, but I had no means of weighing them.

The cases above referred to are very different from that shown in Chart 2, which may appropriately be termed "typho-malarial," or, without using this compound, is fully accounted for by Trousseau when he states that enteric fever in its early stage may simulate malarial fever. Here, at all events, was a case of enteric fever in which the morning temperature was normal on the ninth, tenth, and eleventh days of the disease, while in the second week the variation between the morning and evening temperature ran from three to four degrees. The stools were not considered to be like those of typhoid, but on the fifteenth day spots, both rose and blue,

Digitized by Google

were noticed; the tongue was dry, brown, and cracked, and the nervous stage was well developed; on the twenty-fifth day the man died from intestinal hæmorrhage. The necropsy, contrary to what one might expect from Surgeon-Major Meyer's suggestion, showed Peyer's patches and solitary glands ulcerated for a distance of six feet above the valve; the hæmorrhage came from a patch a few inches above the valve. But I presume this last type of case is not the kind that is called "typho-malarial"; it seems to me that one meets few of them, and the fact that they have been noted renders it almost unnecessary to introduce a new term for them. Surgeon-Major Meyer's remarks are those held by many medical officers in the Army, and are, I believe, to the effect that because some important symptom or symptoms are absent the case cannot be one of enteric fever, and the lesion after death, because it is confined to the lower six inches or so of the ileum, which is thickened and extensively ulcerated, is asserted not to be the ulceration of typhoid. I cannot explain why the ulceration should be so limited; but undoubtedly in some cases it is so, and there is nothing beyond but some degree of congestion.

The conclusions I am inclined to arrive at, after twelve years' experience and notes in tropical and subtropical climates, are: (1) That enteric fever is in the very large majority of cases as readily recognised abroad as at home. That some cases of enteric fever are masked by malaria, chiefly at the onset, but that some enteric fever symptoms will become prominent at some stage of the disease, and when death occurs the character of the gut lesion will, I believe, disappoint those who expect it to differ from that in the most easily recognised case. I have notes of a case that was not returned as enteric fever, though to my thinking some symptoms of the disease were present; during a relapse on the forty-seventh day of the disease phlegmasia dolens of the left leg occurred, which strengthened and verified the belief that it was a case of enteric fever. (2) That what is called "typho-malarial fever" would be more aptly expressed by "bilious remittent." (3) That what I understand by the affection termed "typho-malarial fever" causes almost no mortality; I never saw a death from it in nine years' Indian service.

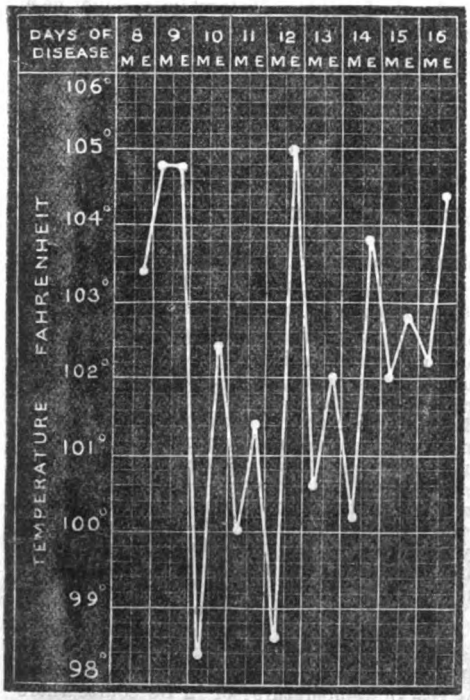

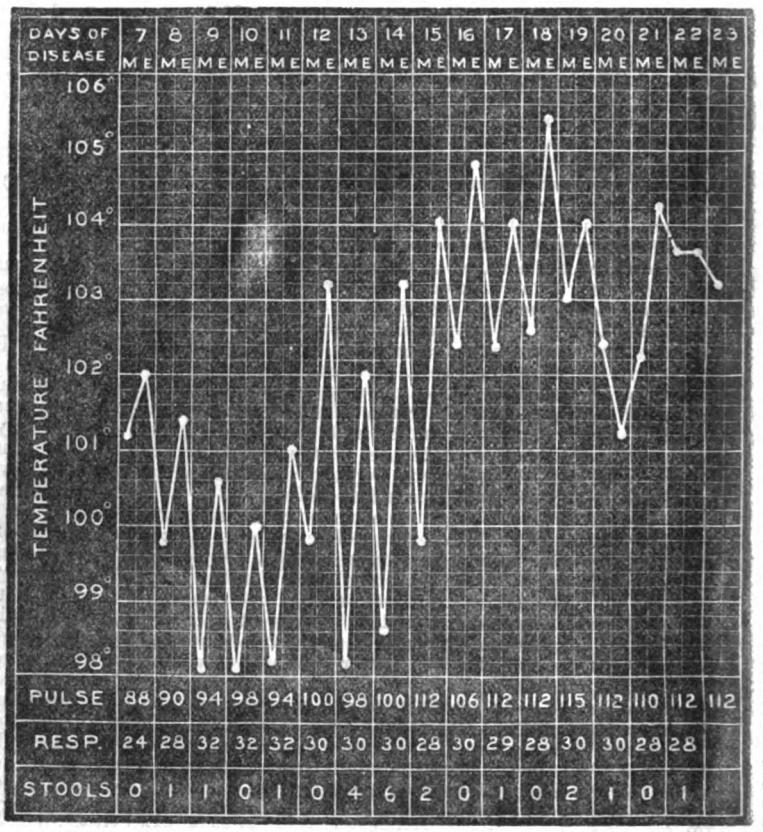

CHART 2.

AN INQUIRY INTO THE SEVERE SYMPTOMS OCCASIONALLY FOLLOWING PUNCTURE OF HYDATID CYSTS OF THE LIVER.

BY LAURENCE HUMPHRY, M.B.,
ASSISTANT-PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

IT is a familiar fact that an outbreak of urticaria or an erythematous rash not uncommonly appears on the skin of patients a few hours after puncture or tapping of a hepatic hydatid cyst. This may be the only discomfort experienced, but occasionally symptoms of an urgent nature, or even fatal, occur within a few minutes after the most simple operation on these cysts. An instance in which the symptoms were very alarming, occurred in a patient lately under my care in Addenbrooke's Hospital.

G. S——, a tailor, aged twenty-three, living at Newmarket, was admitted on July 14th, suffering from well-marked jaundice, and with a painless enlargement of the liver. The upper limit of dulness was at the fourth rib, and the lower border of the liver could be felt a hand's breadth below the ribs. In order to clear up the diagnosis, a hypodermic needle was inserted at the eighth interspace in the mid-axillary line, and half a drachm of clear hydatid fluid drawn off. The patient hardly felt the puncture, but a few minutes after he was seized with extreme faintness and dyspnœa, his face became livid and pale, and his lips blue; he vomited two or three times, and the pulse failed at the wrist; his extremities became cold, and the heart sounds were almost inaudible. Stimulants were given and a sinapism applied over the heart, but he remained in this collapsed condition for nearly half an hour. A profuse irritable urticaria then appeared on the abdomen and legs, and on the extensor aspect of the arms. The chest and face were free from eruption, but were covered with a copious sweat. The rash persisted for a few hours, then gradually subsided, and the

Digitized by Google

patient had fairly recovered by the next morning. Rather more than a fortnight afterwards, there being no alteration in the size of the cyst, I was anxious to aspirate; but being apprehensive of a recurrence of the previous urgent symptoms, it was decided, with the hope of averting them, to inject subcutaneously a small dose of atropine before the operation. A fiftieth of a grain was given hypodermically, and fifteen minutes afterwards the aspirator needle was introduced and nineteen ounces of clear hydatid fluid drawn off. The patient had no bad symptoms, although he was in great alarm, and soon afterwards the jaundice disappeared, the cyst contracted, and he left the hospital well.

It occasionally happens that puncture of a hydatid cyst of the liver is immediately fatal, and I remember once to have witnessed such an unfortunate accident. A fatal case was recorded by Mr. Bryant in the Clinical Society's Transactions, vol. xi., in which sudden death occurred five minutes after the operation of tapping a hepatic hydatid. Three cases are mentioned in Dieulafoy's treatise on Medical Aspiration, in which the patient was seized with intense dyspnœa, and urticaria soon after tapping these followed by the appearance of an erythematous rash or urticaria the following day, with rise of temperature and sore-throat, were observed. I am not aware that these complications have occurred after puncturing other tumours of the liver or in suppurating hepatic abscesses, and the assemblage of symptoms closely resembling those sometimes met with after eating shell-fish would point to the conclusion that the contents of a hydatid cyst contains some poisonous substance which obtains entrance to the system at the time the cyst is punctured. In the hope of determining this, I presented some of the fluid from the cyst after aspirating my patient, and asked Professor Roy the same day to inject it into the peritoneal cavity and veins of some animals. This he kindly did with me, with the following results:—

1.—An injection of 6 cc. of hydatid fluid was made into the jugular vein of a guinea-pig, previously chloroformed. This was followed by some increased frequency of respiration, and the heart's beats were observed to be slowed. A further dose of 8 cc. was given, with the same result. Very slow recovery ensued from the narcosis. The animal was killed within about one hour.

2.—An injection of 6 cc. of the fluid was made into the peritoneal cavity of two guinea-pigs, but no obvious effect followed within the half-hour during which they were watched. Both died during the night.

3.—Fairly large dog (cross from a Colley). Chloroform narcosis was continued during the whole of the experiment. Cannulæ were fastened in the jugular and carotid, the latter being connected with the kymograph. Blood-pressure equal to 140 mm., mercury. Pulse 68; respiration 24 per minute. 12 cc. of fresh hydatid fluid were slowly injected into the vein. In about five minutes the blood-pressure, which showed variations in height, after the injection, was found to be 135 mm. (hydrarg.). Pulse 70; respiration 37. Ten minutes later 14 cc. of hydatid fluid were injected into the jugular. No marked change resulted. Twenty minutes after the first injection 20 cc. of hydatid fluid were injected into the jugular, causing the blood-pressure to sink gradually during the five minutes following the injection from 137 mm. to 63 mm. (hydrarg.). Pulse slowed to 33; respiration slowing down to 17 per minute. As the animal appeared to be dying, a small dose of sulphate of atropine was injected into its vein, which was followed by a gradual but continual rise of blood-pressure until it remained at about 125 mm. (hydrarg.), although during the rise 40 cc. of hydatid fluid were injected at an interval of about five minutes between the injections. The pulse rose to 72 and respiration to 28. The animal was killed. The chief characteristics of the necropsy were the enormous congestion of the liver and the free flow of urine from the cut surfaces of the kidneys.

Professor Roy remarks: "It may be concluded from this experiment, so far as is possible from a single experiment, that there is in hydatid fluid some substance which has a powerful effect on both the heart and the respiratory mechanism. From the first two doses but little effect on the rate of the heart beat was produced, but on giving a larger dose the slowing of the heart from 70 to 33 per minute is very striking. The acceleration of the respiration by the first dose and its great slowing by the dose of 20 cc. of hydatid fluid are also remarkable. The great fall of the blood-pressure after the third dose shows that the fluid from hydatid cysts contains some substance which can affect the blood-pressure in the systemic arteries to a very serious extent. The marked change in the rate of heart beat, the respiration, and the blood-pressure after atropine seems of much interest as well as of practical importance." The hydatid fluid may enter a wounded vein at the time of puncture, or escape into the peritoneal cavity and be subsequently absorbed, and the rapidity of onset and urgency of the symptoms would be the indication. In the post-mortem account of the fatal case recorded by Mr. Bryant, it was found that immediately inside the hydatid capsule the trocar had transfixed a very large vein, which on subsequent dissection was found to be the trunk of the portal vein, and it was supposed that, after withdrawal of the trocar, hydatid fluid escaped into the portal vein and acted as a fatal poison. It may be questioned whether there is not a greater liability, where the close method of tapping is employed, for the fluid to find entrance into one of the dilated veins, which are sometimes found in the fibrous atrophied liver tissue round the cyst, should one happen to be wounded; and whether the treatment by incision advocated by some may not be found safer.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

INDIARUBBER TUBING IN THE BLADDER; SUCCESSFUL REMOVAL.

By WALTER FOWLER, M.A., M.B., F.R.C.S.,
LATE CASUALTY SURGEON, QUEEN'S HOSPITAL, BIRMINGHAM.

THE case published by Dr. Henry O'Neill in THE LANCET of Oct. 30th, 1886, reminds me of a somewhat similar one that came under my care in the Queen's Hospital, Birmingham.

J. G——, aged thirty-two, was admitted on Oct. 17th, 1885, with the following history:—For the last nine months he had been in the habit of passing about six inches of indiarubber tubing from a baby's feeding bottle down his urethra. Three days before admission, while indulging in this habit, the tube slipped from his grasp and disappeared from view. Since then he had complained of pain in the hypogastrium, painful micturition, very red urine, and diarrhœa, and had also had several shivering fits.

On admission there was evidence of severe cystitis. A No. 9 catheter was easily passed into the bladder.

October 18th.—Under chloroform I introduced a No. 12 steel sound, and then a No. 14 after incising the meatus. I then passed a small flat-bladed lithotrite; and, after three or four unsuccessful attempts, I managed, by reversing the blades of the lithotrite, to pick the tubing up off the floor of the bladder, and extracted 8½ in. of tubing such as the patient had described. In the evening he had a rigor and a temperature of 106°, which speedily yielded to ten grains of quinine.

On the 19th and 20th he only complained of a slight discomfort on passing urine, and on the 21st was discharged well.

Old Burlington-street, W.

MENORRHAGIA A FREQUENT SYMPTOM OF PYONEPHROSIS.

By JAMES OLIVER, M.B., F.R.S. EDIN.

IN the human female the reproductive and urinary organs are evolved from the same fœtal structures—the Wolffian bodies. When fully formed, these bodies occupy nearly the whole extent of the abdominal cavity of the fœtus, and constitute a pair of symmetrical organs in structure closely analogous with that of the permanent kidney. Whenever in the animal economy we find organs developed from a common primordial structure, we can invariably prove the perpetuation of a direct nerve communication, whereby impressions originating in one may be forthwith transmitted to the others of a like structural evolution. By acute irritation of the renal and uterine nerves we are able to produce experimentally, through an existing nerve anasto-

Digitized by Google

mosis, a temporary paralysis in the lower limbs—a so-called reflex paraplegia. In the Planaria the primordial liver consists of nothing more than a few cells scattered along a tract of the intestinal surface, which secrete efficiently for the requirements of the organism. As we ascend the scale of animal life, however, we find these cells by agglomeration and multiplication forming a distinctly projecting nodule from the perivisceral wall of the bowel into the perivisceral cavity, and eventually culminating in the production of that large and apparently independant organ—the liver. It is therefore a gland which, secreting into the intestinal canal, is developed from the coats of the gut. The existence here of a free nerve inter-communication is evidenced by the fact that the passage of a slightly acid fluid into the duodenum determines forthwith a copious secretion of bile, whilst that of an alkaline fluid produces little or no effect. Menorrhagia is a symptom frequently associated with pyonephrosis in the early days, and more especially when this disease appears on the left side of the body. It is the manifestation of a mere augmented and prolonged functional activity of the uterus and Fallopian tube, determined in some occult manner by the condition of the renal organ, whilst the periodicity of the flow itself is undisturbed. In such cases I have failed during life to detect any evidence of disease in the generative tract, and have twice verified this fact by a careful examination of the body after death, the uterus, Fallopian tubes, and ovaries being perfectly healthy.

Montague-street, Russell-square, W.C.

PREGNANCY COMPLICATED WITH OVARIAN TUMOURS; TAPPING, DELIVERY, AND SUBSEQUENT REMOVAL OF CYSTS.

By H. F. BAILEY, M.R.C.S., L.S.A.

ON June 5th last I was called to a lady, aged twenty-nine, whom I was to attend in her first confinement. This was about a fortnight before term. I found the abdomen excessively large, and both legs œdematous, blue, and mottled. Palpation revealed fluctuation with distinct thrill, and percussion resonant flanks, with dulness over the rest of the abdomen.

The diagnosis was left ovarian cyst, and, as the tumour was very tense and the patient evidently in imminent danger from rupture of cyst, I tapped about two inches above the umbilicus and removed two gallons of ovarian fluid. Five days later labour came on, and with forceps a healthy female child was born. Lactation was permitted for three months, but the tumour again filling rapidly, the child was weaned.

On Sept. 14th I operated, aided by my partner, Dr. J. N. Miller, Mr. Cooper giving methylene. On opening the abdomen by a four-inch incision, not only was there the left cyst as diagnosed, but the right ovary was the seat of a second tumour, a very dense-walled dermoid cyst weighing 2 lb. I removed the left cyst in the usual way, tying the pedicle by transfixion with Chinese twist and returning it. The tumour of the right ovary was next removed in like manner, and its pedicle also returned. Only one adhesion of omentum required ligature and division. After thorough sponging of the cavity, the incision was closed with silk sutures passing through the whole thickness of the abdominal wall, a Keith's tube inserted, and the wound dusted with iodoform and dressed with Gamgee pads and strapping. The tube was emptied of coloured serum every six or eight hours for a couple of days, and then removed. The dermoid cyst contained epithelial matter and much hair, the whole mass having the appearance and consistence of mortar; the cysts and contents weighed over 25 lb. Recovery was uninterrupted; the evening temperature on the day of operation was 100°; pulse 88. The next day the pulse and temperature were normal, and remained so.

Dr. Fenwick begs for information as to the relation of pulmonary phthisis to ovarian disease. In this case careful inquiry failed to elicit any family history of phthisis, but the patient's parents were first cousins. I suppose the right cyst had remained nearly stationary in size for years, and that gestation determined the rapid growth of the left.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. GEORGE'S HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF THE VAULT OF THE SKULL; PARALYSIS OF THE RIGHT ARM; TREPHINING; RECOVERY.

(Under the care of Mr. PICK.)

THE following belongs to the class of head injuries about which the rule as to operating is simple. The exact locality of the cerebral hemisphere on which there was pressure was doubtful, owing to the large area of bone depressed; but the centre of this area was easily ascertained by reference to Reid's base line. For the notes we are indebted to Mr. Bull, surgical registrar.

G. W——, aged sixteen, a milk-carrier, while delivering milk at some area steps was struck on the head by a falling ladder. He was picked up insensible. On admission (April 7th, 1886) he was unconscious, and bleeding from the nose and mouth. There was a semicircular scalp wound about two inches long over the left parietal bone, and at the bottom of this there was a ridge of bone and a depression about a quarter of an inch in depth. The extent of this depression could not be ascertained, as it passed beyond the full length of the scalp wound. There was slight twitching of the right arm. He vomited some blood, and became conscious four hours after admission. Next day he was restless and irritable. He answered questions, but was drowsy at times. There was slight paresis of the right arm, but no marked paralysis. He was able to move his legs, and had entire control over his sphincters. The bleeding from the nose and mouth had ceased. The wound was dressed and was looking quiet. Next day, forty-eight hours after the accident, the lad was more drowsy, and unless roused he lay quietly on his back. There was marked paralysis of the arm, and the grasp of the hand was very feeble.

After consultation, Mr. Pick (ether having been administered) made an incision across the wound, and reflected the soft tissues. A piece of bone measuring about 3 in. by 2 in. was depressed and wedged below the non-depressed part. The centre of this area was 2½ in. behind the left external auditory meatus, and 3 in. above Reid's base line. A crown of trephine was removed, and after a ridge of bone had been sawn off by a Hey's saw Mr. Pick was able to prise up the depressed bone to its proper level. There was no injury to the dura mater. No ligature was required. A drainage-tube was inserted, the flaps united with silver sutures, and wet carbolised gauze dressings applied.

The patient passed a good night, and was cheerful and conscious next day. His temperature was irregular for a few days, and the wound was foul for four days. At the end of the first week the paralysis began to diminish, and from this time he slowly improved. The wound did well, and in five weeks the lad was sent to a convalescent hospital, on May 12th. At this time there was slight paresis of the arm and hand. He remained in the country five weeks, and on returning was found to have completely recovered the use of his hand and arm.

GENERAL LYING-IN HOSPITAL.

CASE OF CERVICAL EMPHYSEMA FOLLOWING PARTURITION; REMARKS.

(Under the care of Dr. R. BOXALL.)

FOR the following notes we are indebted to Dr. W. G. Holloway, house-physician.

Mrs. S——, aged nineteen, a well-developed but somewhat delicate-looking primipara, was admitted towards the end of the first stage of labour on August 26th, 1886. Full dilatation of the cervix was reached at 10.20 A.M., and the head passed slowly through the pelvis in the first cranial position. It remained two hours on the perineum, and was eventually

Digitized by Google

expelled without artificial aid at 1.50 P.M. The labour pains were very strong, and towards the end became almost continuous. The patient meanwhile screamed violently. The child, when born, weighed 6¼ lb. The placenta was expressed a quarter of an hour after the birth of the child. The uterus subsequently contracted well.

About three hours after delivery the patient herself was aware of a soreness in the neck and upper part of the chest. It began about the left sterno-clavicular articulation, and thence spread upwards and to the opposite side of the neck. Next morning (27th) a puffy swelling was observed at the root of the neck over the manubrium sterni; it was a little tender on pressure. The skin retained its natural colour. At the apex of both lungs, and especially the left, the percussion note was hyper-resonant and the breath sounds feeble. The patient had a slight cough, but no disturbance of breathing. The heart sounds were normal, but at the base were masked by crackling.

On Aug. 29th, during the physician's visit, the following notes were made:—Slight fulness is apparent about the lower part of the neck on either side, but especially the left. The respiratory movements are rather less marked at the left than at the right apex. Over the puffy area emphysematous crackling is easily distinguished by the finger. It is most marked over the manubrium sterni, but does not extend below its junction with the body of the sternum. It can be felt on either side immediately below the clavicle, extending as low as the upper border of the second rib and outwards as far as the coracoid process. It is more prominent on the left side, extending backwards as far as the edge of the trapezius (where it appears to end abruptly) and upwards to within an inch of the mastoid process, but is less distinct and only brought out by deep palpation. In the anterior triangle it again becomes distinct, extending upwards quite as far as the ramus of the jaw and across the middle line to the opposite side. On the right side of the neck it is as distinctly felt in the anterior triangle as on the left side, but cannot be felt in the posterior triangle. No crepitation can be felt under the trapezius, over the mammæ, or down the front of the sternum below the junction of the manubrium and body. Over both anterior and posterior triangles on the left side, and over the anterior on the right, a high-pitched hyper-resonant note is readily produced. The percussion note below the clavicle on the left is slightly higher pitched than on the opposite side. Over the whole area above described superficial crepitation sounds are audible. These are especially numerous on first applying the stethoscope to the surface, and are readily brought out by shifting its position, and are produced, though to a less degree, by the inspiratory movements. In addition, over the pulmonary cartilage they accompany each systole of the heart. No corresponding sound is heard over the aortic cartilage, though no emphysematous crackling can be felt; nor can any sounds be produced by pressure of the stethoscope below the junction of the manubrium with the body of the sternum; crepitation sounds are audible, synchronous both with each inspiration and with each systole of the heart, and extending as far down as the xiphi-sternal articulation, on the right side to the border of the sternum, and on the left a finger's breadth beyond it. In the neck, over the whole area affected, slight pectoriloquy is audible, and the voice assumes somewhat an ægophonic character. The skin still preserves its natural colour. The soreness is diminishing.

Aug. 31st.—No emphysematous crackling can now be felt below the right clavicle, and only very little above it. Over the manubrium and in the supra-sternal notch it is still distinct, and also in the left supra- and infra-clavicular depressions. It is disappearing from below the ramus of the jaw on the left side.

Sept. 1st.—The fulness about the neck has subsided; the hollows are more apparent. Slight emphysematous crackling is still present on the left side in the posterior triangle, and very little over the situation of the sterno-mastoid, but is still distinct at the sterno-clavicular articulation, in the supra-sternal notch, and immediately below the clavicle. On the right side it has disappeared from below the clavicle and from the anterior triangle of the neck, but can be indistinctly felt over the middle of the sterno-mastoid and along the anterior border of the trapezius.

2nd.—The emphysematous crackling has entirely disappeared from the right side, and on the left is limited to the situation of the sterno-clavicular joint and infra-clavicular depression. The crackling sounds accompanying the systole of the heart have also disappeared. The soreness has gone.

3rd.—No trace of emphysema can be detected.

8th.—Mother and child discharged well.

No special treatment was adopted. The temperature remained normal throughout; the pulse varied from 72 to 80, and the respirations from 20 to 24 per minute.

Remarks by Dr. R. BOXALL.—Few cases of cervical emphysema, the result of bearing down during labour, though not very rare (about 1 in 2000 deliverances), have been fully reported. Dr. F. H. Champneys, in an elaborate scientific inquiry on this subject,[1] refers to some twenty cases or more reported by various observers. As the result of experiments made on still-born fœtuses, the same observer concludes that "the cause of emphysema of the neck during labour is rupture of the lung tissue—the air escaping near the root of the lung, passing beneath the pulmonary pleura into the anterior mediastinum, and so beneath the deep cervical fascia into the neck"; and further, that "the air emerges from the thorax along the great vessels, but may not become superficial till it has travelled higher up." The clinical facts of the case quoted above are entirely in accordance with Dr. Champneys' observations. It seems highly probable that air escaping at the root of the lung found its way into the anterior mediastinum; hence the crepitation sounds, synchronous with both inspiration and with the heart's systole, audible over the front of the sternum, where no air had escaped into the tissues superficial to the bone. The air travelling upwards along the pulmonary artery would give rise to similar sounds, heard over the pulmonary cartilage with each systole of the heart; thence travelling onwards and directed upwards by the deep cervical fascia, the air entered both anterior triangles of the neck, and on the left side (where it commenced, and which throughout was more affected than the right), passing beneath the sterno-mastoid, inflated the posterior triangle, and on either side passed over the clavicle as low as the upper border of the second rib and corresponding part of the sternum. Subsequently a little air appears to have found its way also beneath the right sterno-mastoid into the posterior triangle of the same side. In the primiparity of the patient, the severe expulsive pains, the onset of the emphysema soon after labour (often during the second stage), its proclivity for the region of the supra-sternal notch, the absence of disturbance to the respiratory function and of the other serious symptoms beyond the disfigurement, together with the invariable tendency to absorption of the air by the end of a week or ten days, this case, though much less severe in character than many, agrees with the majority of those previously recorded.

NEWCASTLE-ON-TYNE INFIRMARY.

TWO CASES OF SUPRA-PUBIC LITHOTOMY; REMARKS.

(Under the care of Dr. HUME).

THE following are reported on the ground that the position of the supra-pubic as an alternative to lateral lithotomy, as well as some of the details of procedure in the first operation, being still unsettled, it is desirable that the record of cases should be as full as possible.

CASE 1.—T. M——, aged thirty, was admitted on Sept. 4th, 1886, suffering from the usual symptoms of stone in the bladder. These symptoms had been present for twelve months; during the last two months the urine had been turbid and micturition very frequent. At the time of admission the urine was alkaline and muco-purulent. The stone was readily detected by the sound, and seemed to give a hard ring. Measured with the lithotrite it was found to be an inch and a quarter in what was thought to be its shorter diameter; but on account of the sensitiveness of the bladder some little difficulty attended this examination. It was determined not to crush but to remove the stone by the supra-pubic method as an alternative to lateral lithotomy. The operation was performed on Sept. 9th. The rectum was first distended by Petersen's bag, into which were thrown twelve ounces of water. A like quantity of corrosive sublimate solution (1 in 2000) was then injected into the bladder, causing it to rise half way to the umbilicus. An incision three inches long was made above and over the margin of the pubic bone and the dissection carried down to the bladder wall. The plexus of veins in the overlying

[1] Med. Chir. Trans., vol. lxvii., 1884.

Digitized by Google

fat and in the wall of the bladder was large, and required careful separation with the finger-nail and a director. A sufficient surface being cleared, a sharp hook was fixed in the wall and a puncture made. Into this the right index finger was insinuated, and by the side of it the index of the other hand. The stone was then caught with ease between the two fingers and lifted out. On the collapse of the bladder the peritoneal reflection came into view. A drainage-tube was placed in the bladder, and the opening into the viscus was not sutured. Two stitches were placed in the upper part of the wound in the abdominal wall. The after-treatment consisted in retaining the patient alternately on one side and the other, and in the use of salicylic wool to absorb the urine. The patient's progress was satisfactory. The temperature on the evening of the operation was 101°; on the following day it was 99° in the morning and 101° in the evening, from which time it fell, and continued a little above normal. The tube was removed from the bladder on the fourth day, and a soft catheter in the urethra, which had proved quite useless, was discontinued. Urine was passed by the urethra on the fourteenth day. The quantity so passed gradually increased as the wound closed. This, however, proceeded slowly, and was not complete till Oct. 21st. The stone was a uric acid calculus, with phosphatic coating, measuring an inch and a half in its long diameter.

CASE 2.—J. G——, aged sixty-four, was admitted on Oct. 28th, 1886. Had symptoms of stone for four years. With the sound an irregular stone, giving a very clear metallic ring, was detected. It was thought to be an oxalate of lime calculus of considerable size. The patient's prostate was markedly enlarged, and on account of this fact, as well as the character of the stone, the supra-pubic operation was chosen. The operation was done on Nov. 2nd, the details being precisely the same as in the former case. But the veins in front of the bladder were larger and more engorged, as was to be expected; and their walls seemed friable, so that they were torn even with the gentlest handling. Bleeding was thus a troublesome feature of the operation, and some time had to be spent in arresting it. The peritoneum was not seen. The after-progress was satisfactory; but the wound granulated slowly, and till its complete closure on the thirty-seventh day after the operation no urine was passed by the urethra. A few days afterwards the patient returned home in good health, with the wound soundly healed, and entirely free from urinary symptoms. The stone was a mulberry calculus, weighing 6 drs.

Remarks by Dr. HUME.—In the first of these cases a mistake was made as to the character of the stone. It might have been dealt with readily by lithotrity. But, looked at in comparison with an ordinary case of lithotomy by the lateral method, the point which it chiefly offers in contrast is the length of time taken in healing. The supra-pubic wound is at a great disadvantage for healing, in point of position and drainage, compared with the wound in perineal lithotomy. Several cases of primary union after the supra-pubic operation have now been recorded, but these, I believe, have all been in children. In them the abdominal position of the bladder, leaving it even when collapsed in direct relation to the wound in the external parts, and also the natural rapidity of the healing process in early life, render union by first intention probable, and therefore to be aimed at. But in the adult, the bladder, when its contents have all escaped, lies at the bottom of a deep hole, and it is difficult to suppose that in such a wound primary union can be other than the rarest event. And when the attempt to secure it fails the accurate suturing of the external wound will tend, as Sir H. Thompson has pointed out, to increase the risk of urinary infiltration. One may therefore look on it as probable that in the adult the supra-pubic wound will continue to be treated as an open wound, and that slowness in healing will be an unimportant drawback—but still a drawback—to the operation. The second case was typically one in which, according to the views now gaining acceptance, the high operation would be selected. The stone was a hard one, large for lithotrity, in an elderly patient with enlarged prostate. In this condition of the prostate the risk of hæmorrhage in the lateral operation is considerable, and there is a tendency in these cases for cystitis or other chronic urinary trouble to be left behind. The first of these dangers is certainly smaller in the high operation, and it may prove also that the tendency to after-troubles is less marked.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Suture of Divided Nerves.—Physiological Effects of Massage.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. The discussions on both papers were lengthy, and the meeting was prolonged till 10.30.

Mr. J. BLAND SUTTON read a case of Suture of the Median Nerve ten weeks after division, with recovery of function. This paper contained the details of the case of a porter, who through the bursting of a soda-water bottle sustained a deep wound of the wrist. The median nerve had been completely divided, and the parts supplied by it were deprived of motion and sensation below the point of section. Ten weeks after the accident the ends were found by dissection, the cut ends vivified and united by suture. Sensation began to return in five days. The most important feature in the case was the ease with which the ends of the severed nerve were found by following the rules which had been gained by studying the effects of neurotomy in horses. A list of previous cases of secondary nerve suture accompanied the paper. The time taken in the restoration of function may vary from one day to a year.—Mr. HOWARD MARSH said that the operation indicated by the author had been practised a great many times with success at St. Bartholomew's Hospital, both by himself and colleagues. — Mr. T. HOLMES said that it was doubtful whether the fibrous band alluded to by Mr. Sutton was even generally present. In cases where there had been considerable laceration the operation proposed would be very difficult, and any such guide in human subjects would probably be absent. It was only in a few cases that the nerve could be clearly defined. But the operation was urgently needed in any case of division of nerves. In a case of division of the musculo-spiral nerve, in which many months had elapsed before the secondary suture was performed, complete restoration of function ultimately took place. Where the division had been recent, perhaps the function of the nerve would be restored soon. The simplicity of the injury that divided the nerve would certainly have some influence on the rapidity of restoration of function.—Mr. BOWLBY said that he agreed with Mr. Holmes that as a rule there was no definite band of fibrous tissue uniting the nerve ends, and this was especially the case when there had been much suppuration following the original accident. The operation was comparatively easy in some cases, but in others the difficulty in finding the lower end of the nerve was very great. In order to arrive at any conclusion as to the result of an operation it was necessary to follow cases for a sufficient length of time, even for years. If there was no sloughing or suppuration the final result was generally satisfactory. In Mr. Sutton's case there was not enough information to decide whether the success was complete. He would like to hear more about the state of the muscles. It was evident that in cases where the injury was an old one not only the nerve but muscle had to be remade. The first sign of restoration was a return of voluntary power, and this might precede the return of electrical reaction by months, even a year. He was convinced that the lower end of the nerve could be regenerated without being brought into contact with the upper end of the divided nerve. Thus it might happen that union of divided ends, even after a long time had elapsed, would be followed by very rapid restoration of function. There was no danger of tetanus following primary or secondary sutures of nerves, and as cases of improvement after secondary suture had been recorded as long as fourteen years after injury, the operation should never be refused.—Mr. R. BARWELL related a case of division of the ulnar nerve in a girl aged sixteen, in whom he sewed the two ends together with strict antiseptic precautions, and with the result of rapid and finally complete restoration of function.—Dr. W. H. MURRAY said that in Mr. Barwell's case there was the reaction of degeneration in the muscles supplied by the divided nerve, but the abductor indicis retained faradaic irritability.—Mr. J. W. HULKE referred to a point of practice which had not been touched upon. If there were so wide a separation that it was difficult, if not impossible, to bring the two ends together, what should be done? Foreign surgeons had united them by

Digitized by Google

sheep's sciatic and dogs' sciatic nerves, and apparently with success. A method of side-splicing the divided nerve, and bringing down this so as to join the two ends, had also been practised. Cylindrical decalcified bird's bone had also been used. The Germans reported successful results in such cases.—Mr. W. HAWARD remarked on the great variation in the time that elapsed between operation and restoration of function. This variation was doubtless due to many circumstances, some of which he considered. Considerable suppuration about the original wound might cause the central end to undergo an inflammatory change, and interfere with restoration when secondary nerve suture was attempted. Again, suppuration attending the operation for union would also interfere with the result. In a case of neuroma of the median nerve, requiring removal of an inch of the nerve, function was restored in five days. This was doubtless due to accurate apposition, but soon after erysipelas set in, and the function of the nerve was gradually lost again, and two months elapsed ere it was re-established. The value of shampooing, friction, and exercise in promoting restoration to health was referred to.—Mr. B. SUTTON, in reply, said that his patient could perform the delicate operation of writing. He considered this a sufficient test of restoration of muscular function.

Mr. SYMONS ECCLES contributed a paper on the Physiological Effects of Massage (communicated by Dr. Lauder Brunton, F.R.S.). Four distinct manipulations are briefly described, and their immediate effects on the human tissues and functions, as observed by the writer in a series of experiments on healthy persons, are noted: *Effleurage* stimulates the skin muscles, produces dilatation of the superficial vessels and insensible perspiration, excites the skin reflexes, and, acting through the cutaneous nerves, increases the rapidity of the circulation and heart's beat. *Pétrissage* forces the lymph out of the muscles, increases the velocity of the blood-current through the part, temporarily decreases the size of a limb, and increases its muscular power. The pulse-rate is reduced, especially in abdominal kneading. *Massage à friction* produces the same local effects as *pétrissage*, and is peculiarly applicable to joints. *Tapotement* excites muscular contractions. The immediate and remote effects of massage as a combination of the above-named manipulations are: that the texture of the skin is improved, the sense of locality is increased, the general body temperature is raised, and the free surface temperature of a part under massage is higher than that of the rest of the body, while abdominal massage decreases the surface temperature of the extremities. A course of massage of one month's duration increases the body weight, the appetite, muscular strength, and ability to sleep and work well.—Dr. HERMANN WEBER thought the paper of great value. Medical men should themselves superintend and instruct in the treatment, which has often been wrongly used, as in cases of rheumatic fever, acute joint inflammation, acute sciatica, and other affections.—Dr. W. S. PLAYFAIR said that the paper was one of great value. He had taken, however, more interest in the forms of the disease in which massage could be used than in massage itself. As one remedial agent in a certain class of cases—neurasthenia—it was most important, but not more important than other methods of treatment, such as removal of unwholesome domestic surroundings. He fully recognised the importance of scientifically studying the physiological effects of massage. Many patients put on several pounds a week. In many cases the total weight of the body has been doubled in six or eight weeks. The proper selection of cases for massage was very necessary. In a few uterine cases he had seen good, but not very remarkable, results. Reference was made to a case of destructive disease of one lung regarded as hopeless, in which 6 st. weight was put on in the course of some weeks. This hyper-feeding in phthisical cases was well worth further investigation. He believed that any hysterical apeptic could by this treatment be made in the course of two weeks to eat, assimilate, and digest more than a private in the Life Guards could in a similar space of time. It was perfectly ridiculous to suppose that two years were necessary to acquire the masseur's art. One who has not the aptitude never would learn it. But it may be learnt in a month.—Mr. W. HAWARD thought that Dr. Weber's suggestion that medical men should have charge of cases was highly necessary. In lateral curvature of the spine and infantile palsy massage was most valuable.—Dr. DOUGLAS POWER said the patient referred to by Dr. Playfair showed evidences of extensive disease in the lung. Cases in which such a treatment could prove valuable were few in number. The phthisis must be one-sided and past the stage of active process, and in that of "elimination" with hectic, not continued fever. The patient was unable to take sufficient food, and suffered in consequence. It would be extremely valuable in bringing a patient through this eliminative period of disease. Writer's cramp was another affection favourably benefited by massage. Medical supervision was most necessary. He had known a nurse to induce hæmaturia by rubbing, contrary to instructions, an abdominal tumour.—Dr. ARTHUR GAMGEE said that there was a difficulty in acquiring all the methods of application of massage. A thorough anatomical education was necessary in treating infantile paralysis by massage, in which disease no method of treatment was so valuable. In Scrivener's palsy it was of great value. Massage could modify the condition of internal organs. A case of severe gastric symptoms was related, following on consolidation of lung, which had subsided under treatment at the Riviera. The gastric dilatation and functional albuminuria disappeared, and the patient gained three stone in weight. In many cases of phthisis massage and attempted hyper-feeding would fail.—Mr. ECCLES, in reply, said his observations dealt with healthy persons alone.

MEDICAL SOCIETY OF LONDON.

Phosphatic Diabetes.—Wound of Common Femoral Vein.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. RALFE introduced to the notice of the Society a patient suffering from Phosphatic Diabetes, and read particulars of twelve others. These he arranged in groups according to the classification of Professor Teissier, who first gave a systematic account of the affection. Group 1. Excessive elimination of phosphoric acid associated with nervous derangements; three cases. Group 2. Excessive elimination of phosphoric acid associated with phthisis; three cases. Group 3. Excessive elimination of phosphoric acid alternating with saccharine diabetes; three cases. Group 4. Excessive elimination of phosphoric acid running a distinct course, like saccharine diabetes, only without the sugar; five cases. All the cases, with the exception of two, were young adult males. The symptoms common to all were great emaciation, aching rheumatic pains in loins and pelvic regions, dry, harsh skin, with tendency to boils, and ravenous appetite; in some cases cataract develops. In the majority there was polyuria; in others the urine was normal in quantity, with a high specific gravity. The urea was increased in some cases slightly, in others to a greater extent; but the great feature of all the cases was the very considerable and constant elimination of phosphoric acid, with or without increase of the other constituents of the urine—a feature which distinguishes it from insipid diabetes on the one hand and azoturia on the other, with both of which it has been improperly confounded. The pathology, Dr. Ralfe thinks, depends not so much on increased metabolism of nervous matter as on defective nutrition, so that the tissues are not able to utilise the phosphorus brought to them, and consequently a greater amount passes through the system daily. In those cases, in which an excessive excretion of phosphoric acid replaces saccharine diabetes, it is probable that acids like oxy-butyric-glycollic, &c., formed by imperfect oxidation of the sugar, dissolve out the earthy phosphates from the tissues, which appear in excess in the urine. As regards the prognosis in these cases, it is most unfavourable in the first two groups; country air, massage, cod-liver oil, may for a time do good, but the patients rapidly fall back, and either are carried off by some acute attack proving fatal in their exhausted condition, or drift on into phthisis, or into diabetes mellitus. The prognosis of the last two groups is much more favourable: of the three cases recorded in Group 3, two got completely well; the third still suffers from saccharine diabetes, but it remains in a mild form.—Mr. W. A. MERREDITH and Mr. A. P. GOULD made some remarks. In reply to Mr. B. Carter, Dr. RALFE said that there was only the volumetric method, uranium nitrate being the agent used to precipitate the phosphates. Care must be taken that a specimen of the mixed twenty-four

Digitized by Google

hours' urine is used to estimate the daily discharge of phosphates.

Mr. A. P. GOULD read a paper on Wound of the Common Femoral Vein, which will appear in full in a future number of THE LANCET.—Mr. J. H. MORGAN spoke of a case of perforating bullet wound of the sternum, that led to thrombosis of the left innominate vein and pyæmia.—Mr. MARMADUKE SHEILD doubted whether the septic processes were directly due to the wound of the vein with the cat's-meat knife. He thought iodoform should have been freely used.—Mr. GOULD, in reply, said the wound went right across the front of the vein and admitted the finger easily. Iodoform had been dusted around the wound, but not on it. He could not help thinking that the septic poison was introduced at the time of the infliction of the wound.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on Dec. 3rd, James Carter, F.R.C.S., in the chair, the following communications were made:—

Abortion.—Dr. BOXALL read a paper on this subject, and exhibited the fœtus and appendages from a complicated case of miscarriage. During the tenth week of gestation, and as the result of over-exertion on the part of the patient, hæmorrhage set in and miscarriage threatened. The patient kept about for six weeks, but during the succeeding five weeks she was laid up, and ergot was given persistently. The hæmorrhage, however, continued, and her general health suffered. Meanwhile neither the patient nor her medical attendant had suspected the persistence of pregnancy, especially as the menstrual periods had continued regularly during the early months of gestation. An early miscarriage was supposed to have occurred at the onset of the bleeding, and the patient was thought to be suffering from subinvolution consequent upon it. Careful examination, however, detected a feebly-acting fœtal heart, and the uterus was found to reach as high as the umbilicus, and to be partially distended with blood-clot. Two days after this examination the fœtus appears to have succumbed. The product of conception with a great quantity of clots was expelled within the week—i.e., at the end of the fifth month of gestation. It was then apparent that the placenta, though normally situated, had become partially detached; the lower portion had consequently atrophied, while the upper half had undergone a compensating hypertrophy. As regards the causation of miscarriage, the author, referring to the action of ergot on the pregnant uterus, pointed out that, though under certain conditions ergot is a powerful oxytoxic, the drug, being incapable of initiating uterine contractions, is in itself unable to produce premature labour or miscarriage; moreover, that, apart from the various affections peculiar to the pelvic organs of the female, the cause of miscarriage is far more frequently the result of accident than is generally admitted; but, on the other hand, with respect to the syphilitic taint, miscarriage, and especially early miscarriage, is not so generally the direct effect of the syphilitic virus as is supposed, and certainly not to such an extent as to warrant a diagnosis of syphilis from one or more miscarriages when other evidence is not forthcoming.—Dr. W. DUNCAN thought the case reported was a good illustration of the importance of making a careful abdominal examination. He agreed with Dr. Boxall in thinking that early abortions were not nearly so frequently the result of syphilis as is stated in books; but at the same time he had seen cases in which the systematic employment of anti-syphilitic remedies, both before impregnation and during the whole period of gestation, had been attended by the happiest results. Dr. Duncan considered that absolute rest in the horizontal posture, with exhibition of opium provided there were pains, was the best treatment for threatened abortion; but if there were no pains whatever, and hæmorrhage only, he had found that the administration of five or ten drops of the liquid extract of ergot every three hours was of the greatest service.

Cystic Ovaries removed for Dysmenorrhœa.—Dr. WILLIAM DUNCAN showed the ovaries, studded with cysts, which he had removed from a young woman, aged twenty-three, on account of intense dysmenorrhœa, from which she had suffered ever since the onset of the catamenia. She had been subjected to various treatment in different hospitals—viz., blisters to ovarian regions, division of the cervix, introduction of stem pessaries, puncturing the cervix, &c.,—and all to no effect. Dr. Duncan kept her in the hospital for a couple of months, with the daily use of the hot douche; but at the end of that time he recommended abdominal section, having first carefully explained to the patient and her mother what it was proposed to do. Six months subsequently she was perfectly well and absolutely free from any pain. The various conditions which demanded the operation (removal of ovaries and tubes) were then discussed. Dr. Duncan considered that it was perfectly justifiable in (*a*) chronic disease of the ovaries and tubes, especially where there is a history of antecedent pelvic inflammation and a prolonged course of other treatment has proved of no avail, and (*b*) in excessive metrorrhagia due to uterine myoma which is threatening the patient's life, and where the menopause is not likely to ensue for some years. Dr. Duncan disapproved of the operation in hysterical epilepsy.

Hæmatocele from a Ruptured Graafian Follicle.—Dr. WM. DUNCAN showed a specimen consisting of a left ovary with a hæmatocele due to a ruptured Graafian follicle and limited by a piece of omentum. The right ovary contained a cyst about the size of a walnut, which had been ruptured. The patient from whom they were removed had been under Dr. Duncan's care in the out-patient department of the Middlesex Hospital for about a year. She was a married woman, aged twenty-six, with three children, the last two years old. Since last confinement she had suffered from pelvic pains of the usual kind, accompanied by menorrhagia and much dysmenorrhœa. On examination, an elastic, elongated swelling, about the size of a tangerine orange was felt to the left of the uterus, and it was thought to be probably a dilated Fallopian tube. The condition locally remained exactly the same during the whole time the patient attended the hospital, but her general health was much deteriorated. She was advised to submit to operation, to which she consented. Abdominal section was performed by Mr. Bland Sutton, who had no difficulty in removing both ovaries and tubes, together with the hæmatocele and surrounding omentum. The patient made an uninterrupted recovery.

ACADEMY OF MEDICINE IN IRELAND.

Placenta Prævia.

A MEETING of the Obstetrical Section was held on Nov. 26th, 1886.

Dr. FLEMING read a paper on the Etiology of Placenta Prævia, and then went on to enumerate the various ideas as to the source of the blood, giving as the most feasible that of Schroeder—namely: 1. That uterine contractions impel the blood from the place from whence the placenta has been separated. 2. That from the separated portion blood circulating through the chorion villi becomes lost. 3. That unguarded examination may lacerate the placental tissue and so cause fœtal hæmorrhage. The separation of the placenta is most satisfactorily explained as follows:—1. Owing to its formation the placenta cannot adapt itself to the extension of the organ. 2. It is unable to retract with the cervical zone during labour, the membranes being still intact. With regard to the treatment, until within recent years the obstetrician's choice was limited in the early stage, before the os was much dilated, to the following methods:—1. Plugging the vagina, which is ineffectual, and increases the risk of sepsis. 2. Forcible dilatation, version, and immediate extraction—fraught with extreme danger to the mother, as it increases tenfold the risk of post-partum hæmorrhage, owing to laceration of the soft parts. 3. Forcible dilatation and extraction by instruments; this method is, of course, open to the same objection as the last. 4. Separation of the entire placenta; this certainly controlled the hæmorrhage, but inevitably destroyed the child. Dr. Fleming then drew attention to the methods adopted in the Rotunda Hospital for several years past. 1. The membranes are ruptured if the presentation is normal. This acts by allowing the placenta to retract within the lower segment, and by causing the presenting part of the fœtus to act as a plug. This is sufficient in a large number of cases. 2. Intero-external version is performed, a leg is brought down to act as a plug, and expulsion by natural efforts is waited for or aided very cautiously when the os is sufficiently dilated. Expulsion may not take place for a considerable time. The advantages claimed for this treatment are—(*a*) it abolishes the use of the tampon and lessens the risk of sepsis; (*b*) it allows early operation before much blood has been lost; (*c*) it arrests hæmorrhage; (*d*) it enables the patient to rally, gives the os time to dilate, and lessens the risk of post-partum

Digitized by Google

hæmorrhage from lacerating the cervix or vaginal soft parts. 3. In some cases—when everything favours extraction, such as a well-dilated os, and head low down—delivery is sometimes practised with forceps; and, in other cases, it is found necessary to diminish the calibre of the head by perforation and extract rapidly. With reference to the statistics of the cases occurring in the Rotunda Hospital for the past three years, ending Nov. 3rd, 1886, 4514 cases were delivered during this period, and in this collection twenty-three cases of placenta prævia were observed in which there was a maternal mortality of four deaths, three of which were complicated with other serious affections, such as pleuro-pneumonia, sloughing fibroid tumour, and multiple fibroid, preventing contraction subsequently; and one patient was in a collapsed state when admitted. Out of these twenty-three cases eleven infants were lost.

A short discussion, in which Drs. More Madden, Byrne, Kidd, and Mason joined, followed the reading of the paper.

WOLVERHAMPTON AND DISTRICT MEDICAL SOCIETY.

AT the meeting on Thursday, Dec. 2nd, 1886, Dr. S. A. Smith, in the chair,

Dr. EVANS showed the spleen and kidneys from a case of typhoid fever characterised during life by extremely high temperature and treated by cold packing. The organs contained numerous infarcts of various ages. The spleen contained an abscess with ill-defined walls.

Mr. GOUGH read a paper on the Use of Axis-traction Forceps in Midwifery. He described the object, mechanism, method of application, and special advantages of these forceps, and showed that their superiority was not merely confined to the simpler forceps cases, but was of the greatest value in face, brow, and occipito-posterior cases, and occasionally where the after-coming head is arrested at the brim in breech cases. He felt sure that as the old-fashioned straight forceps gave way to the double-curved instruments, so would these eventually be superseded by axis-traction forceps.

Reviews and Notices of Books.

Lectures on Medical Pathology. By H. GAWEN SUTTON, M.B., F.R.C.P. London: Baillière, Tindall, and Cox. 1886.

WE must be grateful for any contribution that tends to present our conceptions of disease in a new light, for there is no denying that our pathological ideas are much restricted by the habit of dwelling upon the proved facts of morbid lesions rather than on the functional derangements which underlie them. Therefore a book like the present is of great value both for what it contains and for what it suggests, awakening thoughts upon trite subjects and presenting familiar facts in a new guise. These lectures, moreover, which have been published from stenographic reports, possess a freshness and a spontaneity which distinguish them very agreeably from the cold formalism of the set treatise. Dr. Sutton is not only a physician, but a philosopher, and, if such a combination be allowed, a poet also. At any rate he exercises freely the imagination of the one mingled with the reasoning of the other. And the whole is welded by the practical mind of the physician, who deduces from the facts of pathology the lines of sound treatment in disease. The lectures traverse a wide field, but they form a connected whole; the same thought runs through them of the nature of disease, and the student is constantly reminded of the influences which act on the organism from without as potent factors in the derangement of health. There is not a page that is not readable, and often one meets with a phrase or sentence that deserves to be recorded as an aphorism, embodying in a few words the sum and substance of a pathological idea. It seems to us that such a work is not one to be dealt with by the captious pen of the critic. It is rather to be accepted with gratitude for the thoughts it contains and the facts on which they are based; and he would be bold who would venture to dispute the latter, however he might differ from the former. The simplest and best course, then, for us to take will be to select, almost at random, a few passages, so that our readers may judge for themselves of the style and matter here presented:—

"By pathology is meant 'a knowledge of suffering and disease.' Then comes the question: 'What is disease?' The great power of nature, unhindered by human ignorance, is always acting 'easy'; this is seen beyond dispute as we study the human body in the construction of the joints, serous surfaces, the heart and vessels; but we in our ignorance hinder the working, and bring about uneasiness, disease, incapacity—and that is the origin of pain." (Page 1.)

"There are many causes of disease; we can never say there is one cause of disease; therefore it is exact to say 'This disease has arisen in these conditions.' As much as possible in thinking about pathology, endeavour to get rid of the word 'cause.'" (Page 3.)

A striking statement in these days of etiological research!

"Blood-circulation is carried on by light and heat, and both are rhythmical." (Page 6.)

"Experience has shown beyond all question that acute inflammation does not supervene in the healthy body. What are the facts which have led to this conclusion? It has been noticed for many years that when death results from acute inflammation there has been antecedent disease, and the exceptions are so few that we cannot but consider that in these we have overlooked the antecedent disease." (Page 10.)

Again, in a few words—but the whole passage is too long to quote—the author sketches the nature of phthisis, and brings into prominence the contending views of its pneumonic or tubercular basis. "The best way," he says, "of regarding phthisis is to recognise that there are external and internal morbid actions taking away the health and substance of the body." (Page 38.)

Here is a remark on bronchitis which illustrates the doctrine held by Dr. Sutton upon inflammation, as quoted above:—

"I know nothing about bronchitis produced by cold in healthy people. Some would say, 'Don't you find primary bronchitis in children?' When I have found bronchitis in children, I have usually been able to trace rickets, struma, or tubercle. Idiopathic bronchitis I know nothing about. Further, 'Does not bronchitis usually prevail in the wet and cold weather of spring and autumn, and is it not produced by those conditions?' Yes, no doubt that is so; but it is in persons who have clear evidence of other disease." (Page 71.)

And many will confirm the truth of this statement—viz.: "Usually persons recover from acute pneumonia, if there be no antecedent tissue degeneration of the lung, extreme blood-poisoning, or violence." (Page 82.)

The lecture on Heart Disease opens with some good advice as to the dealing with persons who have valvular mischief, but in whom the heart is acting with perfect ease and regularity. "So long as the heart is able to carry on the circulation and breathing, whatever sign of damage we may find in the heart, we must avoid discouraging the patient." (Page 84.) Elsewhere, too, we are constantly meeting with shrewd practical remarks which are well worth bearing in mind. Take, for instance, the following, with reference to dietetics and dyspepsia:—

"I used to be in the habit of saying people ought to 'eat properly'; that they should only eat every three or four hours; they should not eat between meals; they should eat and live by rule. But year by year many poor creatures complained dreadfully of their stomachs, of its sinking, and they became so miserable that their days were almost unbearable. The big bell of Westminster tolled hourly on—that is, properly, and their times for eating were regulated accordingly. But as I grew older I looked at the animals, and they were eating and eating, and evidently whenever they could. I learnt at last to thank Heaven that I and others had been made as animals, and with use of reason. Let people eat when it is necessary, let them take food when they want it.

Digitized by Google

The stomach proceeding with healthy digestion is an immense encouragement to the human mind." (Page 123).

We could multiply quotations from this truly fascinating book, but must for obvious reasons bring them to a close in the hope that those we have given may send many to peruse and think over the pages of the work themselves. To show, however, the poetic side of the author's teaching, we may conclude by a quotation from the lectures on Kidney Disease, when, after speaking of œdema and its association with impoverished blood, he goes on to say:—

"Again, let us recall that removing œdema by heat, when œdema was most extreme, has demonstrably on the whole been a failure ending in death. So we have been brought to see that colour in the human circulation, as in the vegetable circulation, is significant of power, simply speaking, of immense power; and we have to recall that colour is due to light, and that the blood owes its colour to light; and that the activity of blood, and the greatest activity of respiration, with its influence on serous circulation and general nutrition, prevail and are manifested when light-energy is most powerful on the earth—in daytime and in spring. And it is beyond question that in anæmia there is failure of respiration in consequence of the corpuscles of the blood being deprived of colour (light) energy." (Page 170.)

And he goes on to point out how plant and animal life is dependent upon light, in passages of much power and beauty, so that one is tempted to say if this be fancy it is fancy controlled and founded on actual scientific fact.

The Refraction and Accommodation of the Eye and their Anomalies. By E. LANDOLT, M.D. Paris. Translated under the Author's supervision by C. M. CULVER, M.A., M.D. With 147 Illustrations. Pp. 600. Edinburgh: Young J. Pentland. 1886.

THIS is undoubtedly the most exact and the most complete treatise on the difficult subject of the refraction and accommodation of the eye that has hitherto appeared. We have every reason for commending the efforts of Mr. Hartridge and others to familiarise students with this branch of ophthalmic practice, but their works are at most rudimentary and are intended only as introductions to its fuller study; but in the work before us we have as precise and complete an exposition as it is possible to give in the present state of science, and there are probably few amongst those who are regarded as professed ophthalmologists who will not derive advantage from a careful perusal of Professor Landolt's well-written and thoroughly practical work.

In bygone times it has been sufficient to enable a man to take a high, if not the highest, rank as an ophthalmic surgeon that he should have had, and should have availed himself of, the large opportunities afforded by a special hospital to acquire a practical knowledge of the principal diseases of the eye, and some degree of expertness in the performance of the ordinary operations. In future something more than this will be demanded of the accomplished ophthalmologist. He should be well grounded in mathematics, and especially in that branch which deals with optics; and he should be perfectly familiar with all that physiology has to teach, which, as the last edition of Funke's Physiology shows, is not a little. He may then hope to deal successfully with some of those forms of defective vision which otherwise present insuperable difficulties to the mere empiric. If there were any additional reason to be assigned for the special study of physiological optics, it would be found in the statement made by Professor Landolt, that at least two-thirds of the patients who consult an oculist suffer from optical disturbances.

The volume before us is divided into three parts: (1) the physical portion; (2) the theoretical portion; and (3) the clinical portion. The first portion deals with refraction, the nature and action of lenses, the formulæ for their refraction, and the dioptrics of the eye. The second portion treats of the mechanism of accommodation, its measure and amplitude, the nature of the chief defects of refraction, and the methods in use of determining the refraction and accommodation of the eye, a special chapter being devoted to astigmatism. The last part is occupied with the more practical side of the subject, with the therapeutics of the chief defects of vision, and the physical means by which they may be corrected. The large number of illustrations, which are excellently drawn, adds greatly to the value of the work. As might be expected, all recent physiological data recorded in the Archives of Ophthalmology and the various ophthalmic journals are well and accurately given, and the author has specially dwelt upon the relations existing between accommodation and convergence.

In conclusion, it is only requisite to state that the translator—Dr. C. M. Culver, of Albany, U.S.A.—has performed the work of translation in a very creditable manner, and that the English presents few or no indications of French peculiarities or idioms, though, from the time that has been occupied in the accomplishment of his task, Dr. Culver must have worked with remarkable assiduity.

OUR LIBRARY TABLE.

Experimental Chemistry. By Dr. STÖCKHARDT and C. W. HEATON. New Edition, revised. London: G. Bell and Sons. 1886.—This book is intended as a guide in the study of experimental chemistry under difficulties. The difficulties consist in the student's not having elaborate and expensive apparatus. The work has been for many years before the public, and has unquestionably proved of service to those students who, in spite of limited means and opportunities, are anxious to acquire some experimental knowledge of chemical science. Mr. Heaton, in producing a new edition, has retained the old methods of Dr. Stöckhardt's principles. Many new details have been introduced in the revised edition. Although written in a popular style, there is nothing that is not in harmony with orthodox chemistry. The first two chapters give a good outline of chemical physics freely illustrated by simple well-described experiments. The third chapter gives an account of the fundamental laws of chemistry, and explains clearly the atomic and molecular hypotheses. The other three-fourths of the book deal with chemical elements—non-metallic, metallic, and organic. The book is neatly got up, and is of convenient size for holding in the hand. It has been carefully edited.

Outlines of Lectures on Physiology, with an introductory chapter on General Biology, and an appendix containing Laboratory Exercises in Practical Physiology. By T. WESLEY MILLS, M.D., L.R.C.P. Pp. 200. Montreal: W. Drysdale and Co. 1886.—This work contains the headings of the lectures delivered by the author for the five past years in the M'Gill College, and will prove serviceable to the students attending Dr. Mills' lectures, but are of comparatively little service to others. We give an example which will allow our readers to judge for themselves. Under the head of gastric secretion Dr. Mills has the following:—"How obtained. Fistulæ. Flow only during digestion. Physical and chemical properties of the secretion. The ferment is pepsin. The acid reaction is owing to HCl present to the extent of 0·2 per cent. The HCl is free. The presence of butyric, lactic, and other acids is traceable to fermentation. Quantity of gastric juice; variations during digestion.

St. Thomas's Hospital Reports. New Series. Edited by Dr. GULLIVER and Mr. CLUTTON. Vol. XV.—The longest and perhaps the most intesting article in this volume is an outline of the history of Art in its relation to medical science, the substance of an introductory address delivered at the Medical and Physical Society of St. Thomas's Hospital, in Oct., 1885, by Mr. William Anderson. There are also further records of surgical experience by Mr. Le Gros Clark; medical cases in which two or more aneurysms were present, by Dr. Sharkey; some cases of neuroraphy or nerve-suture, by

Digitized by Google

Sir William Mac Cormac; osteotomy of the femur for the relief of deformity caused by ankylosis of the hip, by the same surgeon; obscure nervous affections in children, by Dr. Hadden; sanitary science, by Dr. Ed. Seaton; cocaine in dental practice, by Mr. C. E. Truman; some aspects of the vaccination question, by Dr. Robert Cory; results of pre-prostatic puncture of the urethra in forty-six cases in which the operation has been performed in the hospital during the past few years, by Mr. G. H. Makins; cases of perforation of the vermiform appendix, by Dr. W. H. G. Mackenzie; surgical cases, by Mr. Charles Ballance; nerve-stretching for neuralgia, by Mr. Bernard Pitts; neurectomy of second division of fifth nerve, by Mr. H. H. Clutton; museum report, by Mr. Shattock; and reports of the obstetrical, medical, surgical, and ophthalmic departments, by Drs. Cory and Hadden, and Messrs. W. H. Battle and G. D. Johnston.

Alpine Winter in its Medical Aspects: with Notes on Davos Platz, Wiesen, St. Moritz, and the Maloja. By A. TUCKER WISE, M.D. Third Edition. Pp. 138. London: Churchill. 1886.—This appears to be merely a reprint of the second edition, published last year, with the addition of the meteorological observations taken in the Maloja by Dr. Wise from the 7th November, 1885, to the 27th March, 1886, and a few unimportant alterations in the description of the summer attractions in the neighbourhood of the Maloja. We cannot commend the insertion at the end of the book of four pages of laudatory notices of the previous editions, culled from the newspapers.

Illustrated Lectures on Ambulance Work. By R. LAWTON ROBERTS, M.D. Second Edition, with Illustrations, pp. 179. London: Lewis. 1886.—This is a new edition of Dr. Roberts' excellent work. He has added to it a brief sketch of Military Ambulance Organisation, based on materials furnished to him by Dr. Evatt and the Army Medical Regulations. We regret to say that we do not think this has in any degree added to the value of the book, which was originally drawn up as a practical handbook for the use of the working classes, to enable them efficiently to give immediate help to the injured in cases of accident. If all the extraneous matter were cut out and a cheap edition published for the use of the working portion of the population, for whom the lectures were originally prepared, it would form a valuable addition to the works on the subject of first aid to the wounded.

Ambulance Lectures, to which is added a Nursing Lecture. By JOHN W. H. MARTIN, M.D. With Illustrations. Pp. 120. London: Churchill. 1886.—This addition to the list of published lectures on ambulance work seems fairly adapted to the purpose for which it was originally intended, of providing "a reference book of immediate aid to the injured," but we would scarcely accept it also "as a guide to those intending to give such lectures." The lecture on Nursing might be improved without much trouble. In describing the method of changing the upper sheet in a bed, instructions are given how to slip in the clean sheet, but not a word as to the removal of the dirty one. Nor is anything said as to the noiseless method of putting coals on the fire by means of small paper bags. We wonder where the author found the statement that the ancients "named from 4 to 5 A.M. the 'Horæ Fatæ,' or hours of fate."

Dictionary of National Biography. Edited by LESLIE STEPHEN. Vol. IX. London: Smith, Elder, and Co.—This volume contains biographical notices extending from Canute to Chalmer. Its contents show no falling off in accuracy and completeness, so far as by a critical examination we have been able to discover, from those of the previous volumes, of which we have on all occasions spoken with praise. When completed the Dictionary will be well-nigh invaluable.

"Our Young Ladies," by Miss LILLIE HARRIS (London, Walter Scott), contains much useful and pertinent advice to the class of readers for whom it is intended. There is much sound sense in the suggestions offered to young persons of the gentler sex, who would do well to take to heart the somewhat sharp, though not unkindly, criticism which pervades the pamphlet.

POST-MORTEM IRRITABILITY OF MUSCLE.

To the Editors of THE LANCET.

SIRS,—Perhaps the following short account of post-mortem irritability of muscle, observed in a young Hindoo two hours after death, might be of sufficient interest to merit insertion in your columns.

A young Hindoo, aged twenty, was admitted into our wards on Feb. 28th, 1886, and died on Oct. 31st of phthisis pulmonalis. He was a remarkably thin and weakly-looking individual; but although he had a decidedly phthisical aspect, and suffered from cough, general emaciation, and diarrhœa, no dulness was perceptible on percussion of the chest walls. The post-mortem examination revealed a large vomica with infiltrated edges, situated at the root of the left lung, which sufficiently accounted for our inability in detecting any marked alteration on percussion. Numerous small abscesses were also found throughout the substance of the left lung. The intestinal walls were of a dull clay colour. A most peculiar phenomenon in connexion with the voluntary muscles, however, more especially attracted our attention. About two hours after death had taken place, one of our students, who was inspecting the body, percussed the pectoral region, and, to his great astonishment, noticed that the muscles responded most energetically to the stimulus conveyed by the percussing finger, and contracted very promptly. On examining the muscles, I was able to produce most vigorous contractions of the biceps and flexor muscles of the arms, the pectorals, the sterno-cleido-mastoids, the masseters and temporals, and also of the rectus femoris and other muscles of the lower extremity. The biceps and pectorals, especially, responded very promptly, and the contracting muscular fibres of the biceps in some instances rose to certainly half an inch above the level of the quiescent portion. The muscular substance itself was very soft and doughy to the feel, and of a pink colour. Although I have very frequently seen a stimulus call forth fibrillary muscular contractions in emaciated persons suffering from phthisis, I have never before observed the same phenomenon in such a remarkable degree of intensity on the body of a person in whom life had already been extinct for two hours, and I should be much interested to know if this post-mortem phenomenon is common in cases in which the patient has very gradually succumbed to a chronic exhausting disease. Perhaps I should also add that the temperature at the time these observations were made was 90° F., and that the time of the year was what is here called the "dry season."

I am, Sirs, yours truly,

JOHN H. SPITZLY, L.R.C.P., M.R.C.S. Eng.

Military Hospital, Paramaribo, Surinam, Nov. 30th, 1886.

"UNUSUAL CASE OF ORBITAL TUMOUR."

To the Editors of THE LANCET.

SIRS,—Under this heading Mr. T. H. Bickerton in your issue of Dec. 11th, publishes a very interesting case of orbital tumour, much resembling one fully described in "Erichsen's Surgery" (last edition). The tumour, however, a malignant sarcoma, was removed by Mr. Heath, and again enormously developed, penetrating the ethmoid, frontal cells of frontal bone, nares, and pharynx, the patient (a relative of my own) dying at the age of twenty-one, having suffered from the age of four years when several polypi were removed from the nose. Previously to death, proptosis of the right eye amounted to about three inches, and of the left about five inches, having the appearance of an eye fixed on a tumour the size of a cricket-ball. Sight was perfect in the right and fairly normal in the left—a remarkable feature, considering the necessary enormous amount of lengthening of the optic nerve. The brain was clear even at her death.

I remain, Sirs, yours truly,

W. C. ROCKLIFFE,

January, 1887. Ophthalmic Surgeon, Hull Royal Infirmary.

THE LANCET.

LONDON: SATURDAY, JANUARY 15, 1887.

ANY complete or accurate account of the cholera epidemic of 1886 will be impracticable until official reports on the subject have been issued by the Governments of the countries concerned. But the statistics issued from time to time from official Italian sources have proved during the two previous years to be in the main correct, and, in so far as they have erred, it has not been in the direction of exaggerating the extent of the previous prevalences. The 1886 returns, which we are now able to summarise, may therefore be taken as affording a fairly true account of the diffusion of cholera in Italy. As regards Austria-Hungary the matter is different, for whilst reasonably regular returns were received from some parts of the empire, only the vaguest rumours were made public as to the extent of the disease in many large provinces. Subject to the limitations here indicated, it will, however, now be possible to give some general account of the diffusion of cholera in Europe during the third year of the epidemic of 1884–86.

During the close of 1885 and at the commencement of 1886 cholera was lingering about the southern portion of Spain and the north of France, but in neither of these countries did it exhibit any tendency to spread as the spring and summer advanced. From Italy there was no cholera news during the early months of last year, and it was not until the middle of April that the public learnt for the first time that fifteen deaths had occurred in the important port of Brindisi, and that the disease was rapidly extending. Bari, a neighbouring port town, was next attacked, and very soon it was found that cholera was also prevailing in the city and province of Venice, and that it was extending towards the Austrian frontier. Including the province and the city of Venice, 235 cholera deaths had occurred before the end of May. With the months of June and July the disease steadily spread, a number of additional places were attacked in the south; and in the north, whilst the infection was persistently maintained in the province of Venice, it had also become widely diffused in the provinces of Ferrara, Padua, Bologna, Vicenza, and Ravenna; it also clung with special tenacity to a number of places lying on the low lands near and to the south of the mouths of the Po. In these districts the disease gave evidence of further extension during the month of August, although to the south, at Bari, Brindisi, and in the province of Leece, there were signs of abatement. But at the same time extension also took place in the south, and at Barletta, San Marco in Lamis, and Acquaviva the disease prevailed with great virulence. The disease also made its way into the vicinity of the Bay of Naples, but its progress there was fortunately not great. Even its extension into the city of Naples was each time controlled, and it is to be hoped that the Neapolitans may be led to see how even one great sanitary improvement, such as the provision of a fine service of water, probably saved the southern city from renewed disaster. In all there had by this time been about 546 cholera deaths in Italy.

Then came the beginnings of a general abatement of th disease throughout the kingdom, and in the main it may b said that the epidemic still remained confined to the sam northern and southern districts which had been invade earlier in the year. As October set in a further diminutio became evident, and this continued into November, excep in so far as a sudden and somewhat violent outbreak a Genoa is concerned. The movement of troops from infecte localities into the northern port is alleged to have brough about this extension, which caused nearly 115 deaths befor it ceased. Forming a rough estimate of the total extent o the disaster in Italy during 1886, it may be stated that no less than 15,700 persons were attacked with cholera, an that nearly 6500 died.

In Austria-Hungary cholera appeared in the province o Trieste very soon after the disease had established itself i the province of Venice, and during the month of July th malady had already caused a very considerable mortality in Trieste and its neighbourhood, and at Fiume. In th provinces of Trieste and Istria the disease was maintaine throughout the whole course of the epidemic, the principa places attacked being Trieste city, Fiume, Pola, Isola Rovigno, Grado, Gradisca, and Gorizia. But the disease als made its way into Croatia and Dalmatia, and a continuou mortality was for a long time maintained in the Croatia villages, the only available statistics as to which were statements of total deaths during specified periods. During the month of September the important town of Raab became infected, and owing to its situation fears were at one time expressed for the safety of Vienna on the one hand and Buda-Pesth on the other. The outbreak at Raab ceased with a total of 24 deaths, but Pesth was very soon invaded, the mortality being steadily maintained there from the middle of September to the third week in November, when over 1200 persons had been attacked, and nearly 500 had died. The extensions to Vienna were fortunately quite unimportant, and they were in each instance at once checked. Whilst the disease was still in progress in the provinces in the north-east of the Adriatic, the province of Carniola was attacked; and at Szegedin, in the heart of the empire, a serious outbreak involving some 200 lives took place. Later on, and quite into the month of November, scattered outbreaks were occurring, and the disease spread into Galicia to the north and across the Servian and Roumanian boundaries to the south and east. Accurate statistics as to this epidemic are at present quite unobtainable. It may, however, be stated that in the city and province of Trieste nearly 700 fatal attacks occurred, and that it was in this neighbourhood that the disease most persistently maintained itself. Quite up to the close of the year cholera was still heard of in various parts of Austria-Hungary, and its reappearance there next summer is by no means improbable.

It only remains for us to refer to a statement made that during the later portion of the epidemic in Venetia the disease, as then observed, bore little or no resemblance to true Asiatic cholera, although it was so regarded in official places, all deaths being included under the heading of cholera. How far this may have been due to the fact that with an abatement of cholera another fatal

Digitized by Google

disease, having a diarrhœal character, had occurred in the province, or that during the final stages of an epidemic which had prevailed in Italy during portions of three successive years true cholera had lost its essential characteristics, and was, under the circumstances of Europe, lapsing into an ill-marked form of disease, we cannot as yet say. We believe that a report on the subject will soon be forthcoming, and it will be looked for with considerable interest by those who desire to learn all that can be ascertained concerning the etiology of cholera in Europe.

A GREAT many circumstances conspire to make the question of medical providence on the part of the working classes one of unusual interest at the present time. The question is always one of deep interest to our profession. Other professions can be largely dispensed with by the poorer classes. Not so with ours. Poverty only increases the medical wants of its victims, rendering them more liable to many infectious diseases, as well as to many seasonal ones, than those who are more comfortably situated. As medical men, we are sought for by the poor, by night and day. And, for love or for money, we have to obey the summons. And there is no fear of getting so much money for our services by any scheme yet propounded, that we shall be able to dispense with that great kindliness which has hitherto done so much gratuitously for the poor. But there are special reasons why we should at present consider the question deeply. Our gratuitous services are not appreciated as much as if they were the subject of a proper contract. The poor themselves are said to be demoralised by not being required to pay what they can for medical services. The hospitals are said to be impoverished, directly and indirectly, by doing for the poor what medical practitioners should be paid for doing. Medical practitioners complain bitterly of their patients and their occupation being taken away by the abuse of the Out-patient Department of hospitals, special hospitals, and dispensaries. There are ample reasons for believing that the working classes can and should pay much more to the medical profession than they do. One of these reasons is to be found in the fact that many working men make excellent private patients—reasonable in their demands, grateful for attention, and honest and prompt in the payment of their bills. They pay with cheerfulness bills which mock the pittance with which industrial medical societies have lately starved rather than paid their medical officers. Another proof of the ability to pay is the readiness with which the working classes will expend large sums for quack medicines which take their fancy or excite their faith, to say nothing of the enormous sums they waste, and worse than waste, on drink. All these considerations and many more unite to give this question an urgency which it has not had for years. It is receiving a corresponding amount of attention. As our readers know, a committee was lately appointed to study it in all its bearings, and it has already had one or two sittings (the last on Tuesday) under the presidency of Sir SPENCER WELLS. Two or three papers on the subject are before us as we write. One, on the "Wants of the General Practitioners of the Day," an abstract of an address to the West London Medico-Chirurgical Society by its president, Dr. F. H. ALDERSON, may be read in THE LANCET of Oct 30th, 1886; another, the Sturge Prize Essay, on the "Causes of the Financial Depression in London Hospitals, &c.," by Mr. NELSON HARDY, will be found in the *Philanthropist* for January. A third paper is by Dr. MAUNSELL, whose experience of Friendly Societies' provident medical institutions has been great, and whose paper is entitled "Summary Views on Medical Aid." DR. MAUNSELL found it difficult to work under the hard and exacting conditions now popular with such societies; but, to his credit be it said, he has not allowed his experience to embitter him, or abate a most kindly interest in the reasonable settlement of this question.

We wish we could see in any of these papers a sign of the settlement of the questions now agitating the profession. Mr. HARDY looks chiefly to a better understanding between hospitals and provident dispensaries, in virtue of which hospitals shall decline most of their out-patients, relegating them to one or other of a list of provident dispensaries that is to be kept on the premises. There is something to be said for this recommendation, and it would tend to help the dispensaries. In acting in this direction, though perhaps not to the extent indicated by Mr. HARDY, the hospitals would excite much public gratitude and create a claim for more liberal support. But we do not see that it would greatly diminish their financial depression. It is notorious that hospitals do not spend much money on out-patients. Mr. HARDY himself does not estimate the direct expenditure in this way as more than £15,000 a year, which would not go far to meet the deficiency which so harasses their treasurers. He despairs of any adequate attention to this great question from Governments which are influenced mainly by what will bring parties into office and keep them there. But he has hopes that the Royal Family, especially in the Jubilee year, may bring their great influence to bear on the problem, and relieve the hospitals of an incubus that cripples them sadly Her Majesty the QUEEN has never been insensible to suffering, especially among the poor, and if hospitals have not had so much direct help from her as they sorely need, it is probably largely because their wants have not been brought adequately under her notice. We should be sorry to see the Jubilee misused or abused to endless indirect purposes, but of metropolitan charities that deserve to profit by it in this glorious year we place hospitals far above all the rest. One of the best features in Dr. MAUNSELL'S treatment of the subject is his clear recognition of the unsatisfactory working of many so-called provident experiments, notably those by the great Friendly Societies acting in combination and exacting enormous labour for the lowest possible remuneration, with the result of having to appoint chiefly young men in urgent want of employment, who generally resign before long, exhausted or offended by the nature of their work and the ungenerous treatment of their employers. It is fairly to be doubted whether the medical profession on the whole was not better off before any of the provident experiments were in vogue than at the present moment, when providence seems another name for shabbiness.

IT is singular and not without instruction to note how the pathological ideas of one generation, after being discarded and rejected, are often revived and flourish under a new guise. The progress of discovery seems to bring to light these older notions, and to prove how near the truth

Digitized by Google

they were in spite of the disadvantages under which their promulgators laboured. It has been reserved for these latter days to restore the Hunterian doctrine of inflammation, allowance being made for wider knowledge of morbid processes, to its pristine condition. That doctrine for a time dominated pathology, but it came to be modified and ultimately replaced by ideas based upon the facts of cell life and nutrition. An approximation to the teaching of JOHN HUNTER was made when COHNHEIM dwelt on the share taken by changes in the bloodvessels as the essential feature of the inflammatory process; but it was not until the full force of the presence of micro-organisms in relation to inflammation was appreciated that the real truth underlying HUNTER'S views came to be again recognised. Dr. KARL ROSER of Marburg has drawn attention to the bearings of the new teaching upon the old in a monograph which is devoted to a clear and concise criticism of the teachings of JOHN HUNTER and of subsequent pathologists (*Entzündung und Heilung*, Leipzig, 1886). His essay forms a complete vindication of HUNTER'S prescience, and it is gratifying to note how thoroughly the German surgeon has familiarised himself with the teaching of our great countryman. The keynote of the essay is to show that HUNTER was correct in asserting that repair by primary union runs its course without inflammation, and that inflammation is not only totally distinct from the reparative process, but is to be regarded as a secondary complication—a disease which retards rather than promotes repair. For a century, says ROSER, has HUNTER'S teaching upon these subjects been misunderstood or wholly forgotten [with, it must be added, one notable exception—Sir J. PAGET], even by those who have claimed to be his exponents; and the doctrine of inflammation has been by so much confused and perverted. The result has been the greatest diversity of view upon the subject. Some hold that callus is the result of inflammation; others that inflammation is absent in the repair of simple fractures, but occurs in compound fractures from the infection of the wound. Even COHNHEIM, who discriminates between infective and traumatic inflammations, does not detach "repair" from "inflammation." The reason for this confusion lies, it is held, in the neglect of the study of the etiology of inflammation. Too much attention has been bestowed upon the *process*—too little upon its *cause*. It would seem that a mere anatomical definition is inadequate. To attribute the whole series of phenomena to changes in the vessel wall, as COHNHEIM and SAMUEL did, tends to both unnecessarily limit the process and to unnecessarily widen it. It confines it within the limits of vascular supply; it extends it beyond the limits of actual inflammatory change. VIRCHOW was nearer the truth in rejecting the lesion as the essential factor, and replacing it by the "irritant." If by "irritant" we mean "microbe," we get the key to the etiological definition, and the solution, according to ROSER, of the disordered action known to us as inflammation. Practically, the acceptance of this view, which draws a sharp line of demarcation between the reparative process and the inflammatory, is of considerable value. It introduces into inflammation, as its essence, the principle of infectiveness, and of destructive processes dependent on the action of external living agents. It leaves the healing process as the natural outcome of the nutrition of the tissues—a restorative process to be fostered and guarded from the invasion of those external agents which would excite inflammation in the healing wound and derange the normal course of its repair. Union by first intention occurs in the protected clean wound; it is non-infective and non-inflammatory. Healing by second intention is complicated by the intervention of inflammation; the wound has become infected. This is the modern interpretation of HUNTER'S doctrine, and the standpoint which must be assumed in regard to repair and inflammation. The old terms have lost their former significance, but the facts they described, when considered by the light of modern discovery, seem naturally to fall into place. Fifteen years ago HÜTER and KLEBS were the first to point out the importance of infectiveness—i.e., the intervention of micro-organisms in the inflammatory process; but naturally such teaching could not conform with views like COHNHEIM'S.

In pursuing the subject further, Dr. ROSER shows that HUNTER does not say much regarding the causes of inflammation. He refers to local or constitutional tendencies as altering the blood and interfering with primary union, and does not consider that air itself could excite inflammation. And we now know that he was right; for if air be thoroughly aseptic, it is innocuous (ZAHN). Again HUNTER distinguished between inflammation and suppuration. We now know that both are due to the presence of micro-organisms. OGSTON found that all acute abscesses contained micro-organisms, but did not detect them in cold abscesses; but since KOCH'S discovery of the bacillus tuberculosis, renewed investigations have resulted in the detection of micro-organisms in the walls of cold abscesses (SCHUCHARDT and KRAUSE). It was pointed out by COHNHEIM that inflammation and suppuration can be excited by irritants injected into bloodvessels; but it is a question whether such results can be regarded as inflammatory apart from the presence of micro-organisms. HUNTER even conceived of pus being of vascular origin, and was in this sense as much a precursor of COHNHEIM as he is of LISTER; for ROSER points out that the Hunterian distinction between inflammation and repair is precisely that which governs the Listerian methods. As regards other points in the inflammatory process in which HUNTER'S observations and opinions have been verified by the germ theory, reference is made to the fact of inflammatory œdema and the allied process of serous inflammatory effusions. It is doubted whether in either case it is essential for the micro-organism to be present at the actual seat of effusion; but we confess to a difficulty in accounting on this view for the inception of, say, a simple pleurisy. The progress of bacteriology, which has demonstrated the presence of microbes in the pneumonic lung and in the valvular vegetations of endocarditis, will doubtless in time clear up this and similar difficulties; but the essential principle that inflammation owes its origin to micro-organisms is likely to prevail. Another question of interest is the fact of heightened temperature of an inflamed part. Without entering into this question, which has been much debated, and is discussed with tolerable fulness by ROSER, it may suffice to mention that according to this writer the phenomenon depends upon two factors. The one is the old and generally accepted fact of the increased vascularity of

Digitized by Google

the inflamed area; the other is that it is due to the vital activity of the microbes themselves. Here, however, we are in the presence of theoretical considerations, which are of less importance than the recognition of the essential facts which the practice of antiseptic surgery has done so much to demonstrate—viz., that repair is *not* inflammation.

THE report of the Statistical Committee of the General Medical Council, to which we referred in our last week's issue, contains some tables which are peculiarly interesting just now in reference to the movement for granting degrees to the London medical student. The figures given therein trace most accurately the career of those who commenced their professional education on their registration as medical students during the period 1871-75. We regret that there can be no statistics for the next quinquennium, although comparatively few of those who began in 1875-80 will still be without a registrable qualification, if they can ever expect to enter our ranks. The report deals with 6403 students who were placed on the Students' Register during the five years 1871-75, and classed as follows: England (London 2009, or 31·38 per cent.; provinces 1111, or 17·35 per cent.), 3120, or 48·73 per cent.; Scotland 1717, or 26·82 per cent.; Ireland 1532, or 23·93 per cent.; abroad 34, or 0·53 per cent. It thus appears that one-half of the medical students of those years began their education in England. Of the 3120 English students, 349 began in other places of study and pupilage than the large metropolitan and provincial schools, or, in other words, 1 in every 9 was placed on the register either as a pupil at a provincial hospital or as being with a general practitioner. In Scotland only 7, and in Ireland 73, thus began their medical education, and in this respect the English student would have no mean advantage. Commencing professional education in the country and not at a university is practically unknown in Scotland. Out of the total 6403 students, 4472 have registered one or more qualifications, whilst 1931 (30·16 per cent.) have failed to find a place on the Medical Register. The failures are thus distributed: England 858, or 27·50 per cent.—viz., London 528, or 26·28 per cent.; provinces 330, or 29·70 per cent.; Scotland 532, or 30·98 per cent.; Ireland 526, or 34·33 per cent.; abroad 15, or 44·12 per cent. The largest percentage of medical students has qualified who commenced in London, those who commenced in the provinces come next, then Scotland, then Ireland, and lastly those who begin abroad, of whom less than one-half ever obtain a British diploma. Of the 4472 registered practitioners 607 only took a single qualification, and of these no less than 256 became M.R.C.S. Eng. and 99 L.S.A. Lond., and are now presumably practising on one of these qualifications only. Single qualifications are very much less common among Scotch and Irish students. Recognising that the education of the student is practically completed when he obtains a double qualification, we are next told in what division of the kingdom each of the 3865 doubly qualified practitioners began their education, and what proportion migrated into another division for one or both qualifications. The 3865 began thus:—London, 1250; provinces, 603; Scotland, 1099; Ireland, 896; abroad, 17; of these only 7 per cent. in Scotland and 11 per cent. in Ireland remain with a single qualification. The migrations are very clearly placed before us by the following statistics—viz., to England, 20 out of 1185 Scotch students, and 53 out of 1006 Irish students; to Scotland, 464 out of 1481 London students, 419 out of 781 provincial, and 494 out of 1006 Irish students; whilst to Ireland there only crossed 21 from London, 58 from the provinces, and 12 from Scotland who obtained a qualification. If the analysis be carried still further, it will be seen that of these students of 1871-75, 45 from Scotland and 31 from Ireland have become M.R.C.S.Eng.; 41 from Scotland and 19 from Ireland, L.S.A.Lond.; whilst only 4 from Scotland and 3 from Ireland have taken the L.R.C.P. Lond. Of those who went to Scotland for qualifications, 275 from London, 227 from the provinces, and 232 from Ireland became L.R.C.P. Ed. (against 257 Scotchmen); 98 from London, 119 from the provinces, and 228 from Ireland became L.R.C.S.Ed.; whilst 40 from London, 35 from the provinces, and 27 from Ireland qualified at the Faculty of Physicians and Surgeons of Glasgow. The only real attraction in Ireland to those on this side of St. George's Channel is the L.K.Q.C.P.I., which was obtained by 64 English students (Liverpool and then Manchester being the only schools practically represented), and by 10 Scotch students, chiefly from Edinburgh. Of English students 354 qualified at the London College of Physicians, and 502 at the Edinburgh College.

In addition to the question of relative difficulty of examination, we cannot lose sight of the fact that the use of the title of "Doctor" by the licentiates, although not really claimed, was tacitly permitted of the Scotch and Irish Colleges, and is used to-day by very many of these practitioners of 1871-75 on their visiting-cards and door-plates. The feeling of the authorities of the London College against this unfair appropriation of a title was very strong, and most explicitly laid down. The recent combination of the Colleges both in England and Scotland has made a marked difference in the number of London students who now seek the L.R.C.P. Edin., and it will still further affect it.

With regard to the migration for a degree, the figures are no less instructive. The students who entered during the quinquennium 1871-75, and obtained a double qualification, have moved from one place of study to another to gain an M.D. degree as follows:—From London to Durham, 11; to Edinburgh, 8; to Aberdeen, 17; to Ireland, 10. From the provinces to Durham, 3; to Edinburgh, 14; to Aberdeen, 2; to Ireland, 4. From Scotland to the University of London, 2; to other English or Irish Universities, 0. From Ireland to English or Scotch Universities, 0. The only students, therefore, who migrated in search of a degree were English students, and these, with the exception of those going from provincial schools to Edinburgh, were mainly from London. The Aberdeen degree of M.B. could then be taken after one year's residence, and this explains why so many students took a long journey into the north. Aberdeen now demands two years' residence, as do Edinburgh and Glasgow, and the number of London students who now go there, as to Glasgow, is practically *nil*. Durham has come to the rescue, and a year at Newcastle-on-Tyne is for the students of the past decennium a sufficient residential qualification for its degree. The last calendar of this University shows that this short period is an efficient attraction to our average London students, for out of 52 graduates at the M.B. examination in December, 1885,

Digitized by Google

and June, 1886, 34 hailed from London and 2 from Birmingham, whilst only 16 were trained at home. Only 36 candidates passed at the recent M.B. examination at the University of London; so that practically Durham now guarantees the efficiency of as many London men in a year as does the University of London itself. Students from every medical school in London are included in the Durham list, whilst only seven schools are represented at their own University. The uselessness of the University of London to the majority of London medical students could not be more conclusively shown.

DR. STURGES has made out a good case. He strikes hard against the medical ignorance of teachers, guardians, and friends of children. A year or two ago a book was published by a schoolmaster who advocated the appointment of doctors to head-masterships. This no doubt was going too far in the right direction. To all our public schools there are attached medical officers. The Association of Medical Officers of Schools has already done much to place before its members certain codes of rules for uniform observance, especially in the matter of infectious diseases. A not unimportant part of the duties of medical officers of schools should be, and doubtless is, care for and consideration of the hygiology of the nervous system.

We do not suppose that Dr. STURGES' arguments are founded on statistics favourable to the view of the pathology of chorea of which he has been a consistent and ardent advocate. Our contributor cannot be suspected of having so grouped his statistics as to defend his own positions. Yet we might urge that the school, far from being a cause of chorea, was really a preventive of it. We might quote many authorities to show that schooling secured immunity from chorea, or rather that mental training was conducive to the health and nutrition of the cerebral cortex—which last-mentioned organ would certainly not be objected to by Dr. STURGES as the primary focus of the "fidgets and restlessness." We have conceded that there is truth in the author's arguments. The whole fault, however, does not lie in the schooling any more than the whole truth lies in the notion of *school-made* chorea. Eight of the twenty-one cases of chorea attributed to schooling may have been at least partly due to insufficient ingestion of food. The brain may have been forced on inadequate diet, and, likely enough, defective supply of fresh air, or, what is the same thing, overcrowding either at home or at school. Again, we must take account of the family and personal history of each case. In the eight cases inherent instability of the nervous tissues may have been derived from ancestors or acquired from actual disease. Even if all this be granted, still the schooling may have been a not inconsiderable item in the actual production of the affection. The whole causation, so far as external environment goes, is indeed fully familiar to and rightly recognised by Dr. STURGES. Family rows, drunken violence, home cruelty, semi-starvation, the perils of the street, may undoubtedly cause chorea in the presence of the predisposing physiological (or is it pathological?) condition of the cerebral cortex.

The evil comes, as is wisely remarked, from the fact that teachers do not differentiate their material in respect of temperament, mental activity, bodily health, and home circumstances. Mental dulness and wayward behaviour are mostly ascribed to wilfulness and wickedness. Perhaps in nine cases out of ten the teacher thinks that "caning" may arouse mental activity and abate abnormal irritability of temper. When dulness and irritability supervene suddenly about the period of examination, it may not seem unlikely, from the teacher's point of view, that a boy or girl may shirk work and prove troublesome from simple idleness and wilful dislike. The teacher ought to remember that the examination may pervert temper and increase dulness, and this altogether apart from the child's control. The necessity for proper food, clothing, and air being admitted, surely the remedy lies not in teaching the teachers, who have already enough to learn, but in providing competent medical officers to inspect the children from time to time, or to be called in consultation whenever any case of irritability and fidgetiness attracts attention.

Annotations.

"Ne quid nimis."

THE WIMBLEDON SCARLATINA EPIDEMIC.

IN accordance with the announcement which we made last week, the Local Government Board have instituted an inquiry into the epidemic of scarlet fever at Wimbledon and Merton, and it is satisfactory to find that the inspector appointed to this duty is Mr. W. H. Power, who is so well known in connexion with similar investigations. It is now believed that the first announcements somewhat exaggerated the actual number of persons attacked; but since the inquiries, which will show what was the actual amount of disease, have only just been properly organised by the sanitary authority, it would be premature to express any opinion on this point. In the meantime we would point to the fact that the incidence of the disease has been shown to be directly connected with a local milk distribution, the milk coming from a dairy-farm, and being distributed by a tradesman whose only connexion with the farm was that he procured his supply of milk there. The actual means by which the milk became infected is not yet quite cleared up. At first sight, it appeared that it might have been due to an actual case of scarlet fever, for the disease appeared in the families both of the dairy-farmer and of the milk-vendor. The precautions which were taken at the dairy-farm seem to have made it all but impossible that the infection could have emanated from the lad who lay ill there under the closest isolation; and as regards the case in the milk-vendor's family, it appears that milk which was delivered by his men without ever having come near to his premises conveyed infection just as much as that which passed through his premises. Probably the actual dates of these two cases of scarlet fever will go to show whether there is any chance of their being regarded as causes of the epidemic, or whether they were merely two attacks having the same cause as the epidemic as a whole. And this consideration leads us to say that suspicion already attaches to the cows themselves. True, they were examined and declared to be healthy, but examination such as that which sufficed to detect the disease which some time since led to the distribution of scarlet fever from the Hendon dairy will be wanted in order to set this question at rest. It is, however, noteworthy that the epidemic is an exceptionally mild one. Now, this mildness of attack will probably prove to be one of the leading characteristics of scarlatina passing directly from the cow to the human subject by means of milk. When Dr. Buchanan, in his report for 1882, first drew attention to the fact that

Digitized by Google

evidence was gradually accumulating to show that milk carrying scarlatina actually possessed the power of propagating that disease at the very moment when it was received into the pail, and that the cow herself suffered from a disease having strong analogy with scarlatina in the human subject, it was the occurrence of certain mild epidemics of that disease which had led to this conclusion. The fact that there is a cow disease having the effect foretold has since been proved, and the mild epidemic at Wimbledon and Merton may be another example of it.

THE LATE LORD IDDESLEIGH.

THE sudden death from syncope of Lord Iddesleigh, which occurred on the 12th inst. at the official residence of the Prime Minister in Downing-street, under, we may say, dramatic circumstances, although startling to those around his lordship, had not been unforeseen by his immediate friends, and had been anticipated by his medical attendants. The incidence of symptoms pointing to such a termination of the life of so eminent a statesman and so distinguished a public servant may be dated from 1882, on Nov. 23rd of which year the following reference to the matter was made in our columns:—"We regret to learn that Sir Stafford Northcote and Mr. Childers have both broken down in health, and have been ordered abroad for change and complete rest. We are not surprised at it. The work which has devolved upon the former as leader of his party during the last session, and the late hours which were the rule of the House, the very short intervals of relaxation, and the renewed work and worry of the autumn session, would be sufficient to use up the physical strength of even a younger man." The circumstances attending Lord Iddesleigh's decease will doubtless, ere these words are read, be known to our readers, but may be briefly summarised as follows. Lord Iddesleigh left his residence near Exeter on the 11th inst. and came to London, first to make final arrangements with Lord Salisbury with respect to the transfer of the seals of the Foreign Secretaryship and afterwards to attend a meeting at the Mansion House. During his visit to town he was the guest of Earl Fortescue, and on the evening of his arrival appeared to be in good health and spirits, and talked with his usual animation. On the following day (the 12th) he visited the Foreign Office to take leave of the permanent officials, and spoke most cheerfully to his late colleagues in that department. His lordship afterwards crossed to 10, Downing-street, and while waiting to see Lord Salisbury he became faint and fell into the arms of Mr. Henry Manners, Lord Salisbury's private secretary, who had hastened into the room at the first alarm. Medical assistance was at once summoned, and Mr. Langston was early in attendance, being closely followed by Mr. Hebbert. On their arrival the case was at once seen to be hopeless. The beating of the patient's heart was imperceptible; he was indeed completely pulseless. He was lying on his back, absolutely pallid, and just breathing. At the suggestion of Mr. Langston, hot-water stupes were applied over the heart and ether was injected into the forearm. There were no evidences of cerebral disturbance, and an entire absence of convulsive movement. The restoratives administered were absolutely without effect, and after two feeble gasps his lordship passed away peacefully and without a struggle. Lord Salisbury was in the room. Dr. Mortimer Granville, who had previously been consulted by Lord Iddesleigh, was also summoned, but did not arrive until death had occurred. An inquest will not be necessary, as Dr. Granville has given a certificate attributing death to gout, cardiac disease, and syncope. The existence of advanced mitral disease with aortic valvular complication had been clearly recognised. The aortic trouble was the immediate cause of death. Few statesmen have been so sincerely honoured and respected by the people of England; and for uprightness of character, candour, and all the virtues which combine to make, in the highest sense of the word, a man, Lord Iddesleigh has left a name which will not soon be forgotten.

A TRIBUTE TO ENGLISH SURGERY.

MR. TEALE'S "Dangers to Health" has long ago reached a fourth edition, and has been translated into several continental languages—Spanish, French, and German. In the matter of the German edition Mr. Teale has been highly honoured. The book so interested Prof. Esmarch on his visit to England that he determined to translate it. But soon after, he tells us in his preface to the German edition he had the honour of an interview with H.R.H. Princess Christian of Schleswig-Holstein on this subject, and she at once offered to translate the work into German, which she speaks as well as she does English. Esmarch's preface gives an interesting account of the difficulties which arose in getting any German publisher to undertake its publication owing to the cost of the pictures, and from the fact that Germans buy fewer books than the English and French, and thateven German doctors take small interest in these questions, German architects still less, and German landlords least of all. He was wellnigh in despair, till on going to the last International Medical Congress in Copenhagen, and being the guest of a noble Danish merchant, Herr Augt. Gamél, he and his brother, Herr Arnold Gamél, on hearing from Esmarch the difficulties of getting the book published, undertook to place the necessary sum at Esmarch's disposal. This is a very pleasant illustration of the uses of an International Medical Congress. We congratulate Mr. Teale on the honour conferred on his book, by having a Princess for translator, a preface by Esmarch, and such enlightened co-operators as the brothers Gamél. The sound commonsense of English surgery is thus seen to be appreciated and will find imitators, as the antisepticism of Lister has in every country where men wish to advance in health and civilisation.

LONDON MORTALITY IN 1886.

A SUMMARY of the facts published in the Registrar-General's fifty-two weekly returns for 1886 shows that the rate of mortality in London during the year was equal to 19·9 per 1000 of the estimated population in the middle of the year. This rate slightly exceeded the rate in 1885 (which was 19·6, and lower than that recorded in any previous year), but was 1·8 below the mean annual rate in the ten years 1876-85. In the twenty-seven large provincial towns dealt with in these weekly returns, having an aggregate population rather greater than that of London, the mean death-rate last year was 21·8, and 1·9 higher than the rate in London. Previously to 1883 the London death-rate had never fallen below 21 per 1000, whereas in the four years 1883-86 the rate was successively 20·5, 20·4, 19·6, and 19·9. The death-rate in London last year from the principal zymotic diseases was 2·7 per 1000, and was almost identical with that which prevailed in the preceding year. The two most striking features in the mortality statistics of London in 1886 were the comparative immunity from fatal small-pox, and the further considerable decline in the mortality from scarlet fever. Only 5 deaths from small-pox were registered in London during last year, against 893 and 890 in the years 1884 and 1885. Only twice previously since the Registrar-General's Returns were first issued in 1838 have the annual deaths from small-pox fallen below 100; they were 57 in 1874 and 46 in 1875. The deaths from scarlet fever last year were 688, and lower than in any previous year on record, excepting 1841 and 1873, when they were 663 and 645

Digitized by Google

respectively. Allowing for increase of population, however, the mortality from this disease was lower both in 1885 and 1886 than in any previous year of which we have record. The marked decline in the death-rate from this disease in recent years is especially noteworthy; it was 1·13 per 1000 in the ten years 1861–70, fell to 0·60 in the following ten years 1871–80, and during the first six years of the current decennium it further fell to 0·42 per 1000. It may be pointed out that this fall in scarlet fever mortality has been coincident with the existence and increasing use of the isolation hospitals of the Metropolitan Asylums Board. With regard to the other zymotic diseases, it may be stated that the fatal cases of measles and diphtheria last year had declined, while those of whooping-cough and diarrhœa showed an increase upon the numbers in 1885. The 701 deaths referred to fever included 618 from enteric fever, 13 from typhus, and 70 from ill-defined forms of fever; these numbers did not materially differ from those in 1885, but the deaths from typhus were fewer than in any year on record. Infantile mortality, owing to the greater fatality of infantile diarrhœa, showed an increase last year, and rose from 156 and 148 per 1000 registered births in 1884 and 1885 to 159, which was higher than the recorded rate in any year since 1878, when the hot summer raised it to 164. On the whole, the mortality statistics of London last year afforded renewed evidence of constantly improving sanitary condition, and bear most favourable comparison with those of any of the other large European cities.

NASAL TREATMENT OF WHOOPING-COUGH.

A DEFINITE idea has of late gained ground as to the nature and origin of whooping-cough. The idea may or may not be pathologicallly correct; but the treatment founded on it is decidedly of a rational description. What is more to the practitioner, this treatment is said to prove remarkably successful. Correctly speaking, the idea is compounded of at least two factors. One of these is fully as familiar as whooping-cough is common. Micro-organisms are the cause of the affection. The microbe effects an entrance into the economy from a special site, and that site of entrance is the soft tissues of the nasal fossæ. The rational therapeusis is founded on formulæ of an equally explicit character. Antiseptics or germicides will destroy the living germs. They should be used early, and their sites of action are the nasal fossæ. The number of remedies already recommended is sufficiently striking. The method at present in greatest favour appears to be insufflation. Convenient contrivances of different designs for effecting the insufflation may be met with in great variety at the surgical instrument makers. A clumsy but successful insufflator may be contrived by rolling a spill of paper, inserting a little of the powder to be employed at the end that enters the nostril, and supplying the motive force by the parent's or operator's puff of breath. But the puff-balls or regular insufflators are effective and not costly. Iodoform, salicylic acid, and boracic acid are the three antiseptics that appears to be most in vogue. They should all be very fine, almost impalpable powders. Nasal douches are very effective if they can be managed, as in older and not too nervous children. The most effectual douche of antiseptic kind appears to be the 1 in 500 corrosive sublimate. Care is to be taken that no appreciable quantity of this solution is swallowed. Some practitioners employ simple nasal douches in the earliest stages—say, a drachm of Condy's fluid or of common salt to the pint of water. And this is done as much to mechanically wash away secretions with contained contagia as to destroy the germs. Weak solutions of tincture of iodine and of alum are also used. These lotions may be syringed into the nasal passages, or the children may be induced to snuff the lotion up from the palm of the hand. Older children may be taught to take the powders as "snuff." Repeated applications of any of these methods are necessary to ensure thorough topical treatment in the early stages of the catarrh. The antiseptic agents may also be applied, as in young infants, by means of camel-hair brushes charged with ointments, lotions, or glyceroles. It is necessary to clear away all secretions and scabs first, by syringing or anointing with oil. The agent is then directly applied to the bare congested surface of the mucous membrane. An ointment of half a drachm each of iodoform and eucalyptol to an ounce of vaseline is highly commended by some. The boroglyceride may be used in similar fashion, also lotions of corrosive sublimate. Any of the antiseptic solutions may be atomised by the steam- or hand-spray, and inhalations effected through the nostrils. It is doubtful whether the theory of this fashionable method is correct; but supposing it should be, it is equally dubious whether the good that results may not be from the mere treatment of the catarrh as such, apart from its supposed cause. A pledget of cotton-wool or a chamomile flower placed in the nostril to prevent the access of air alleviates the symptoms of an ordinary rhinitis. So it may be with the various applications, the principal of which we have mentioned. Cocaine is now widely used as a 4 or 5 per cent. solution painted on to the nasal and pharyngeal mucous membranes, not only in whooping-cough, but in simple or severe catarrhs.

THE DEGREE FOR LONDON MEDICAL STUDENTS.

AT the last meeting of the Medical Society of St. Mary's Hospital, Mr. A. J. Pepper, M.S., President, being in the chair, the following resolution was proposed by Mr. Edmund Owen, and seconded by Mr. J. J. Clarke: "That, in the opinion of the Medical Society of St. Mary's Hospital, it is expedient that a Degree in Medicine be placed within the reach of the general run of London medical students; and that this Society ventures to express the hope that this may be accomplished through the conjoint influence of the Royal Colleges of Physicians and Surgeons." To this several amendments were proposed, and fully discussed by members of the hospital staff and by the students, but at the conclusion of the debate, which had to be adjourned to a second meeting, the original resolution was carried at a late hour, amidst much enthusiasm, by an overwhelming majority. This is probably the first occasion on which the London medical students have collectively expressed their opinion on this question.

LONDON HOUSE DRAINAGE.

A COMPLAINT has been made by Mr. D. J. Ebbetts against the Commissioners of Sewers of the City of London, to which, no doubt, the attention of this body will be directed. Mr. Ebbetts, in a paper which he styles "a protest," while giving credit to the Commissioners for the efficiency with which the roadways are scavenged and the sewers constructed, says they neglect to exercise any supervision over the manner of construction of house drains, that the builders of new houses are required to deposit at the City office a plan of the proposed house drains, but that the Commissioners limit their action to determining the size of that part of the drain which enters the sewer, and to constructing it as far as the wall of the house; but beyond this they do not concern themselves. The interior drainage and its ventilation, the use of proper fittings, the avoidance of pan-closets and D traps, are not deemed matters for supervision; and hence the City is wanting in one of the most important details of sanitary administration. In the rest of London, as distinct from the City, ample powers are given to the sani-

Digitized by Google

tary authorities to enforce all regulations which they may think fit to make, but, with very few exceptions, the subject is generally neglected, and certainly the principles embodied in the Model Regulations of the Local Government Board, which are largely recognised by provincial sanitary authorities, are disregarded. London so far as house drainage is concerned is deplorably careless, and Mr. Ebbetts' allegation shows that the City cannot claim any exemption from this condemnation. It is, however, only fair to note that building operations in the City are so costly and so well executed, that probably in new houses nearly all that is necessary is done voluntarily by the owners. Much difficulty stands in the way of any London improvement owing to the numerous authorities in whom are vested the right to control house drainage. The Society of Medical Officers of Health have always endeavoured, so far as the duties of health officers are concerned, to reduce to a minimum the disadvantages attendant upon this division, by taking counsel of each other, and we would gladly see a conference held between Metropolitan surveyors with the object of determining a uniform plan which would be accepted by all the local authorities. There appears to be no other method of attaining this object except that of transferring to the Metropolitan Board of Works the duty of regulating and supervising the planning and arrangement of the drainage of newly-built houses.

THE INEQUALITY OF THE PUPILS IN VARIOUS DISEASES.

DR. PASTERNATSKI, who has been working in Professor Chudnovski's clinic in St. Petersburg, has published in the *Vrach* an account of a number of observations he has been making on the inequality of the pupils in various diseases, thus carrying out a suggestion made by his chief in a work on the methods of examining medical patients, published in 1883, in which he expressed an opinion that careful examination of the pupils would lead to interesting results. Dr. Pasternatski examined a number of methods which have been proposed, but did not find any of them suitable for his purpose, and ultimately a much simpler plan, suggested by M. Follin, was adopted. This consists in bringing a catheter gauge card close to the eye, and comparing the size of the pupil with the apertures in the card. By this means the size of the pupil in millimetres can be ascertained with a degree of accuracy sufficient for the purpose. It is important to make the observations in the shade, for the difference, when there is any, between the diameters of the pupils increases as the light is diminished. The best method of conducting the examination is to close the eye which is not being observed, for this causes a slight increase in the diameter of the pupil of the latter, as was indeed remarked by Hippocrates. It was found, for example, in a case in which this was tested, that when both eyes (being in the shade) were fixed on an object at a distance, the diameter of the right pupil was 5½ mm., and that of the left 6 mm.; when, however, the eye not under examination was covered up, the diameters increased to 6 mm. and 6½ mm. respectively. As to the diseases in which inequality of pupils has been observed, Dr. Pasternatski quotes a number of cases mentioned by continental physicians; also one of aneurysm shown by Professor Gairdner to the Edinburgh Medical Society; as well as two reported by Professor Finlayson in THE LANCET of January 3rd, 1885, in both of which aneurysms were found at the necropsy. His own observations gave the percentage of cases in which inequality was found in various diseases as follows: Croupous pneumonia 85, heart diseases and aortic aneurysm 61, pleurisy 52, chronic catarrhal pneumonia 33, acute articular rheumatism 25, catarrh of the respiratory passages 18, scurvy 16, typhus 16, recurrent typhus (relapsing fever) 15, abdominal typhus (enteric fever) 13. Inequality of pupils was also found in half the cases of catarrhal and hepatic jaundice and renal colic. The largest percentage occurred in croupous pneumonia, and study of the cases showed that the position and stage of development of the disease has a remarkable effect upon the pupils. At the very commencement the pupil on the same side as the affected lung is, as a rule, larger than the other. The difference generally increases with the lung inflammation, reaching its height on the third, fourth, or fifth day; before the crisis the difference decreases, sometimes even disappearing. Afterwards, during the stage of resolution, a difference is again manifest, the pupil on the affected side being now contracted. Not only do the pupils in pneumonia differ in size, but also in sensibility to light. Speaking generally, the author's observations lead him to believe that inequality of pupils is most frequently met with in those internal diseases which not only affect the system generally, but which, like pneumonia, pleurisy, and hepatic and renal colic, are definitely localised as well. It is also very usual in heart diseases and aneurysm, but comparatively rare in scurvy and infectious diseases such as typhus, and when it does occur in these it is generally consequent on some complication.

UNREASONABLE CHARGES AGAINST POOR-LAW MEDICAL OFFICERS.

WHEN a Poor-law medical officer has to go nine miles to see a patient, and goes as often as is necessary, it is hard to be found fault with. This was Mr. Gordon Laing's case at Barnstaple. Fortunately, he was able to satisfy the Board that he had been very attentive, and that both the patient and his wife had thanked him for being so. The case of Mr. A. B. Munro of Bradford is similar. He is a district medical officer of many years' standing, and makes "a hobby," as all good Poor-law medical officers do, of having their parish patients attended to as well as their private ones. Mr. Munro complains that the guardians have taken for granted depositions in the coroner's court forwarded to them which "would have been denied on oath and disproved." This is a short way for guardians in dealing with their medical officers, but it is a very unjust one. The Caistor Board of Guardians have had what one of their number characterised as a "storm in a teapot" over the great question whether their medical officer, Dr. Cameron, should "initial on Wednesday or Saturday each alternate week, or after the expiration of Saturday as the close of the week." Surely this is a question which a body of gentlemen could discuss quietly, even if the officer in question be, as one of them said, a "dogged Scotchman" with his own notions of the time for initialing books.

SANITARY CONDITION OF FLORENCE.

The Times has recently given publicity to a number of statements seriously reflecting on the sanitary condition of Florence. It is impossible in the midst of much which is contradictory to discuss this subject, but certainly English people will be slow to visit this city until a thorough inspection has shown that the alarm is groundless or that a remedy has been found for the alleged insufficiencies. The outcome of the discussion is that Dr. Baldwin of Florence is raising a fund to provide Florence with the advice and assistance of an English expert, and has himself liberally contributed to the expenses which would be thus incurred. We trust that those who are interested in its welfare will not relax their efforts, and that through an impartial statement of facts the municipal authorities may be enabled either to acquit their city of the reproach which now attaches to it, or to render it a safe resort for the many who desire to enjoy its beauties.

PREMATURE BURIAL.

MUCH has been said and written concerning the danger of premature burial, and the subject has even become to some nervous persons the persistent horror of their lives. That a few authenticated cases have occurred in which the still living body has been by some strange oversight consigned to the grave we are not disposed to deny. It is probable, however, that the number of such cases has been exaggerated. Too much has possibly been made of the evidence of movement in corpses which have been exhumed. A critic writing on this subject throws the whole responsibility for live burials on our professional brethren. This is a sweeping and certainly an unfair judgment. He accuses them solely on the ground that in many cases they do not, in order to certify death, proceed to make an examination of the supposed corpse, and suggests that certificates of death might be fraudulently obtained by unprincipled attendants on the sick as a preparatory step to murder. Now, this is one of those arguments which, however they may sound in theory, have little, if any, practical meaning. Medical men, we admit, do not always think it necessary to view the body of a deceased patient before certification. In many instances there is no need that they should do so. They have been in regular attendance; have ascertained the nature of disease; have gauged its probable issue; and, finally, have seen the actual approach of death, which in a few hours' time has occurred, and of this they are assured on the testimony of persons whom they know to be well principled and judicious. Surely they are entitled in all the circumstances to accept the statement as true. Where there is doubt either as to the signs apparent or the character of informants, it is the duty of every practitioner to inspect the body of his patient, and any departure from this rule must, we are sure, at all events in this country, be very exceptional.

DEAF-MUTE CHILDREN.

IN August, 1885, Lord Salisbury addressed a circular despatch to Her Majesty's representatives at Paris, Berlin, Rome, Vienna, Brussels, Berne, the Hague, and Washington, requesting them to procure a return showing the number of deaf-mute children in the countries where they resided, and the nature and amount of public aid given towards their education, distinguishing between the sums contributed in each case by the State, province, and commune. From the returns which have been received and recently issued as a Parliamentary paper it appears that in France there are sixty institutions for such instruction, and information was obtained respecting thirty-six. Three of the institutions—at Paris, Bordeaux, and Chambéry—are under the immediate authority of the Minister of the Interior; one is for the benefit of Protestant children, seven are styled "institutions régionales," seven are departmental institutions, one is communal, eighteen are private enterprises, but the majority possess departmental or communal scholarships. In Germany, at the last census in December, 1880, there were 2906 deaf-mutes between five and ten years of age, and 4469 between ten and fifteen years of age. At that date Prussia possessed twenty-four deaf and dumb asylums. There appears to be no uniform system adopted throughout the country for the support and management of its deaf and dumb institutions, but it is left to the provinces to manage their own establishments in the most advantageous manner. The Royal Deaf and Dumb Institution in Berlin is the only one to which the State contributes directly. It receives pupils from all parts of the empire, and trains teachers for the provincial institutions, this last being a duty which devolves upon the State. In Italy, the greatest number of deaf-mutes are between twenty and fifty years of age. Up to the present time thirty-four establishments for their education have been opened. Half of them are charitable institutions under Government supervision, three are State institutes, and the remainder private ones. Eleven of them receive aid from the Treasury, and others are pecuniarily assisted by the provincial and communal administrations, as well as from private sources. According to the returns furnished by the Ministry of Public Instruction, there were in Austria at the census in 1880, 637 deaf-mutes under five years of age, 3390 from six to ten years, 3939 from eleven to fifteen years, and 3489 from sixteen to twenty years of age. The institutions, which number sixteen, receive considerable grants from provincial funds, while several are, moreover, assisted directly by the State. In Belgium, the proportion of deaf-mutes to the rest of the population appears to be increasing. In 1876 only 2070 were returned as deaf-mutes, while on Jan. 1st, 1883, there were 2934 so afflicted. There are ten private institutions under Government inspection and control, and the expenses are, generally speaking, shared between the provincial common fund, the commune the province, and the State, the latter contributing a sum equal to that granted by the provincial authorities. In the United States, as ascertained by the census of 1880, the number of deaf-mutes was 33,878, 18,567 males and 15,311 females, or 0·067 per cent. of the whole population. In the fifty-three public and eleven denominational and private schools for the education of the deaf, tuition is free or practically free, to rich and poor alike, and in general the only expense incurred by the parents is for clothing and cost of removal.

LORD FRASER ON MEDICAL EXPERTS.

ON January 7th a case was tried in the Court of Session, Glasgow, before Lord Fraser and a jury, in which a horse-dealer claimed damages for injuries sustained by an accident on the Caledonian Railway. The defenders admitted their liability, and the only question to be determined by the court was the nature and extent of the disability the pursuer was suffering from. The arm was injured, and was further affected by crutch-paralysis, but the medical witnesses agreed that the lesions were only of a temporary character. The point on which there was so wide a discrepancy of opinion referred to the leg. Drs. Littlejohn, Joseph Bell, and Cameron contended that "the leg was permanently injured through rupture of a muscle, and that the muscle had in consequence lost its contractility." On the other side, Drs. Dunlop, Heron Watson, and Macleod asserted that the injury was of a temporary character, and that the loss of continuity of the muscular fibres would be restored by the natural reparative process. Dr. Dunlop, surgeon to the company, went further, and, in face of the contention that the man could not get his foot to the ground, submitted that the best thing the pursuer could do would be to ride at a gallop on horseback. It is not altogether surprising that to a lay individual the difference exhibited by the medical men on the two sides as regards their respective views of the merits of the case should appear greater than warranted by the apparently simple nature of the injury, and Lord Fraser must be held quite within his rights in passing the strictures he did upon what he termed "extraordinary contradictions and statements." But the practical surgeon knows it is often difficult to determine the exact nature and the extent of an injury to a muscle. Of course, there are some cases in which the signs are too obvious to be misunderstood—e.g., where there is extensive or complete rupture of a muscle, such as the biceps brachii. The mere fact of considerable muscular wasting is not of itself necessarily of great import. Injured muscles waste from disease, as well as from traumatic disturbance of their innervation. The case under discussion reminds us of Sir James Paget's lecture

Digitized by Google

"On Cases which Bone-setters Cure." It is well known that a man may be a helpless cripple from lesion or displacement of a muscle or tendon, and that forcible passive movement and vigorous exercise may, in a surprisingly short period, restore the function of the part. We are not calling into question the *bona fides* of the medical witnesses on either side, but we wish to explain that the divergence of their evidence may have arisen—and probably did arise—from the fact that they could not accurately tell the amount of laceration the muscle had undergone. It certainly was an unfortunate incident that the opinions should have been grouped as they were, those of the surgeons appearing for the pursuer being arrayed against those of the witnesses for the defenders. We have frequently asserted that in all cases of criminal action the medical experts should be appointed by the court of assessors; and we believe that it would be of unmixed good to the community and to the medical profession if the same practice obtained in civil trials.

THE FINANCIAL POSITION OF THE UNIVERSITY OF CAMBRIDGE.

IN his address made to the Senate of the University of Cambridge on resigning his office on Monday last, the Vice-Chancellor, alluding to the financial difficulties of the University, remarked: "We need that it should be proclaimed through the length of England that instead of our University being a wealthy body we are hampered on every side by the want of funds. We want money for our library; we want money to build museums; we want money to build lecture rooms; we want money for laboratories; money to build examination-halls. The increased numbers of our students show the estimate in which our teaching staff is held; surely we may appeal to the wealth of England to enable us to accommodate these numbers suitably, to enable them to partake, in the, to them, most convenient fashion, of the instruction which our professors convey. I conceive that we want at present at least £100,000 placed at the disposal of the University to carry on our work. Judge, then, of the sorrow with which I mentioned that our income falls short by nearly £25,000 a year of that which it was calculated it would be in 1886."

THE FRENCH CENSUS.

THE first official publication of the results of the French census taken on May 30th last has just been issued, and shows the population of France to be 38,218,903. The previous census in France was taken in December, 1881, when the number was returned as 37,672,048; the increase, therefore, during the four years and five months intervening between the two censuses did not exceed 546,855, whereas in the five years of the preceding intercensal period the increase had been 766,000. It is worthy of note with regard to the small increase of population in France in recent years that the recorded excess of births over deaths in the four years 1882-85, with due correction for the additional five months of 1886, was only 395,568, implying that between the last two censuses the balance of immigration over emigration was no less than 151,287. It is known that in recent years the annual number of emigrants from France does not exceed 5000, but it is now apparent that the immigrants to France in recent years must have averaged nearly 40,000 per annum. It appears that the population of Paris has increased but 75,000, whereas from the increase of the population of the Seine department it is evident that the suburbs of the city have grown far more than the city itself. The increase in the population of Lyons, Marseilles, Bordeaux, and Lille, was in each case proportionately larger than in Paris; and in the 53 towns having a population exceeding 30,000 the aggregate increase exceeded 300,000. As in England, the towns in France have mainly increased at the expense of the rural districts; but in France this has caused (which is not the case in England) an actual decrease in the population of the rural districts. In 32 agricultural departments of France the recent census shows a decrease of 110,000 in the population. Of the 87 departments, 58 now show an increasing and 29 a decreasing population, the numbers at the previous census having been 53 and 34 respectively. The increase of population in Brittany (mainly rural), which has a birth-rate considerably exceeding the general rate in France, stands out in conspicuous contrast with the marked decrease of population in the rural portion of Normandy. In still greater contrast is the rate of increase of population from excess of births and deaths in England and France. In the year 1885 the excess of births over deaths in England was equal to 13·5 per 1000 of the population, while in France in the same year it was but 2·1 per 1000.

CHANGE OF COLOUR OF THE SKIN.

A CONTEMPORARY recently drew attention to the decease of a coloured woman at Michigan, whose case seemed to have strangely perplexed the public, and was believed to be without a parallel. When well advanced in years a white patch appeared on the leg; others followed, increased and coalesced until most of her body became white, the face being the last to change colour. From the accounts, it is evident that the case was one of leucoderma, a disease well known amongst whites, but peculiarly frequent in the dark-skinned races, though the relative frequency has been doubted by distinguished authorities, and the impression attributed to the more striking character of the affection. Erasmus Wilson gave its frequency in London as 1 in 400 cases of skin disease, and in another place as 1 in 294; according to Kaposi, it is in Vienna 1 in 500; but Garden, in India, met with 1 in 362 cases of skin disease, and the Bombay inquiries into leprosy disclosed a great number of these cases.

TOTAL ABSTINENCE LODGES AND MEDICAL PRESCRIPTION.

THE public has been very much shocked by a recent County Court trial in which a certain benefit society, bearing the concise name of the "Benjamin Hatfield Lodge of the Original Grand Order of the Total Abstinent Sons of the Phœnix," appeared as refusing the representatives of one of its deceased members the sum due to them on his account, on the ground that he had in his last illness, arising from cancer of the bowels, on the advice of all his medical attendants, taken medicinal quantities of alcohol. The judge, who spoke very strongly against the Lodge, was compelled to yield to the defence on a legal point, the deceased having taken back his subscription. It is behaviour like this that constitutes the intemperance of teetotalers, and estranges so many reasonable people from them and the cause they advocate. We are glad to find that even good teetotalers like Dr. Kerr, whose letter we insert elsewhere, feel as indignant at this Lodge as does the public. In the last extremities of cancer and exhaustion, to deny a poor creature the advantage of a little wine or brandy, ordered by a medical man, is a piece of senseless cruelty, and the sooner all total abstinent benefit societies disown such views absolutely and entirely, the better for them and the cause of temperance. There has been far too much interference of late with the functions of medical men. We shall never fail to point out that their responsibilities are very great. But they are theirs, and must be left with them, not shared by every teetotal prophet who thinks himself an equal authority in medicine and morals.

REMARKABLE MAGISTERIAL DECISIONS UNDER THE FOOD AND DRUGS ACT.

AT the Sheffield Town Hall a druggist was recently summoned under the Sale of Food and Drugs Act, at the instance of the Health Committee, for selling tincture of opium which was not of the nature, substance, and quality of the article demanded. The deputy town clerk conducted the prosecution. Dr. Sinclair White, medical officer of health, proved that he personally purchased at the defendant's shop three ounces of tincture of opium. The sample was duly divided, and a portion submitted to the borough analyst, Mr. A. H. Allen, who certified that "the proportion of opium in the sample was less than one-third of that contained in the tincture of opium of the British Pharmacopœia, while the proportion of alcohol was somewhat more than one-half the proper quantity." The stipendiary magistrate said that no doubt the action of the Health Committee was very laudable, but he was of opinion that if a preparation *contained any opium and any alcohol whatever* it could be legally sold as tincture of opium, and he accordingly dismissed the case. At the same time and place a shopkeeper was summoned under the Act for selling paregoric elixir, which, according to the certificate of the analyst, was "wholly destitute of opium, the most important ingredient of paregoric elixir." Mr. Allen, Dr. White, and Mr. G. E. Newsholme, President of the Sheffield Pharmaceutical and Chemical Society, gave evidence in support of the prosecution, and adduced various authorities to show that opium was an essential ingredient of paregoric elixir. Mr. Allen stated that the existence of paregoric without opium was as impossible as that of whisky without alcohol. If the preparation had no opium in it, it had no right to be called or sold as paregoric. For the defence a druggist was called, who said that he supplied "paregoric elixir guaranteed free from opium" to shopkeepers, so that they might not infringe the Pharmacy Act, they having no licence to sell poisons. He could not name any ingredient of a medicinal value that the paregoric supplied by him contained. The stipendiary said that the name "paregoric" failed to give him any definite impression, any more than "soothing syrup." The prosecutor pointed out that, for all the defence amounted to, they might simply sell coloured water and call it paregoric. The magistrate said he did not see that the law prevented it, and dismissed the case. Mr. J. F. Burnett, F.C.S., in a letter to the *Pharmaceutical Journal*, states that he was present in court during the hearing of these cases, and can testify that the reports are not in the least exaggerated, but are, on the contrary, somewhat underdrawn. These decisions seem to us to be so extraordinary that an application will doubtless be made for a case for the higher court, and we accordingly reserve our comments.

THE MEDICAL HISTORY OF CEYLON.

AN interesting paper, giving a sketch of the medical history of Ceylon, has been communicated to the Ceylon branch of the Royal Asiatic Society by Dr. Vanderstraaten, the sketch being divided into a review of the Singalese, the Portuguese, the Dutch, and the British periods. The Buddhist doctrines early led the rich and wealthy to make some provision for the destitute and the maimed, and thus hospitals and medicine-houses came to be established. Native practitioners of medicine also sprang up, and the system received impetus from the example of some of the kings of Ceylon who, by practising medicine, made it a noble calling. Portuguese priests and others brought in more modern notions, and during the Portuguese period some considerable progress was made. The habit of betel-chewing is spoken of by the author as wholesome, and the Singalese at that time attributed their long and healthy lives to its use; men and women could also be seen who had not lost a single tooth. But small-pox was an invincible disease, and was regarded as an "affair of God." During the Dutch period the Leper Asylum at Hendda was established in 1708, but the medical records of this period are very scanty in their information. During the British period 221,082 persons were vaccinated between 1802 and 1812, and this effort was so successful that for eleven years no small-pox occurred in the island. A striking contrast is shown between the state of the island in 1803, and at the present time. At the earlier date, of seventy-five men, together with the usual complement of officers, all fell victims to the climate except three, during a march from Colombo to Cattadina; whereas Dr. Kynsey is now able to report that the average annual mortality for the whole army is only 9 per 1000. Dr. Kynsey has published some very valuable information as to the sanitary condition and mortality in Ceylon, which taken together with Dr. Vanderstraaten's review of the earlier conditions affecting the island form an interesting chapter in the medical history of Ceylon.

THE WALTER MOXON MEMORIAL.

A GENERAL MEETING of the friends of the late Dr. Moxon will be held at the Royal College of Physicians on Tuesday, Feb. 1st, at 5 P.M., to determine the form of memorial best suited to perpetuate his memory. At this meeting Sir William Jenner, who has consented to act as president of the fund, will take the chair. Among those who have already given their names in support of this object are the President of the Royal College of Surgeons, Sir William Gull, Sir James Paget, Sir Andrew Clark, Sir Thomas Acland, Sir Henry Acland, the Registrar and Treasurer of the Royal College of Physicians, the President and Treasurer of Guy's Hospital, Professor Humphry, Sir William M'Arthur, Dr. Pavy, and Mr. Bryant. We understand that upwards of a hundred gentlemen have already expressed their wish to join in this memorial, and we have been requested to state that previously to the meeting Mr. Clement Lucas will receive the names of those desiring to contribute.

HOSPITAL WANTS AND THE QUEEN'S JUBILEE.

IF the Jubilee of the Queen is to bear all the burden that is proposed to be put upon it, it will be heavily weighted. The editor of the *Hospital* supports the suggestion of *The Times* that the occasion be used for raising a million, to yield £40,000 a year, to meet the deficiency in the income of the metropolitan hospitals. We certainly think that this suggestion is much more to the point than many which have been made. But Her Majesty's own views have yet to be ascertained. She herself and her own personal claims are entitled to first consideration. But it is to be hoped that she will show her sympathy at a time of unprecedented trial for these admirable institutions, which receive no State aid, and which do for the sick poor what in nearly all other countries is done for them by the State.

SYPHILITIC BONE AFFECTIONS AND PRECOCIOUS GUMMATA.

THE Transactions of the American Dermatological Association for 1886 contain some interesting discussions on syphilis. Dr. R. W. Taylor finds that, like certain osseous and nervous lesions, malignant syphilides in general, and many other affections, the gummatous syphilide may occur as early as the second month of infection, but usually in the third or fourth month and beyond that time; that there are three clearly marked forms of these precocious gummata: first, an early general and quite copious form; secondly, a more localised form, which may invade several regions of the body,

Digitized by Google

and is usually symmetrically distributed, but sometimes is confined to one region, particularly one side of the face or scalp and the roof of the mouth; and thirdly, a form in which more or less severe neuralgiæ precede and accompany the eruption, which in many particulars possesses points of resemblance to simple erythema nodosum, but is a direct outcome of the syphilitic diathesis. In a further discussion, Dr. Taylor stated that he believed, from a careful gathering of the paternal history, that dactylitis occurs in about an equal number of syphilitic and non-syphilitic children. With regard to "syphilitic Pott's disease," he did not think it would prove to be so rare as would appear from hitherto published evidence.

THE FOOCHOW HOSPITAL FOR WOMEN AND CHILDREN.

THE first annual report of this institution, which is in connexion with the Woman's Foreign Missionary Society of the Methodist Episcopal Church, has just been published. Although the report now before us is the first one that has been published, the hospital was founded so far back as 1877. It comprises on the first floor a drug-room, dispensary, waiting-room for patients, four small rooms for native assistants and medical students, and a surgery; and on the second floor three wards, affording accommodation for about twenty patients. The number of out-door patients treated from September, 1885, to July, 1886, the period dealt with in the report, was 4832, and of in-patients 218, this last number being an increase of almost 100 per cent. on the figures for any previous year. More accommodation is greatly needed, especially for patients who are able and willing to pay for their treatment, and the executive contemplate the purchase of additional land and the erection of another building. Instruction has been given to four native women in medical subjects, and the establishment of a training school for nurses is contemplated at an early date. The report contains a careful analysis of the cases, medical and surgical, which have come under notice, and gives evidence that satisfactory work is being, and has for nine years past been, carried on by the promoters and active officials of this hospital.

THE TYPHOID BACILLUS.

MM. Widal and Chantemesse have succeeded in carrying researches on the bacillus of typhoid rather further than Gaffky, who described it. The centre clear space is not, they say, characteristic, as Artaud supposed, for it is found in other bacilli, especially in those of old cultures; and it is, they believe, the beginning of the death of the microbe. Spores are produced between 37° and 38° C. It does not liquefy gelatine, and is easily cultivated on potato. Gaffky was unable to find the bacillus in the living subject, or to inoculate it. MM. Widal and Chantemesse have found it during life by making a capillary puncture of the spleen, and they have been able to inoculate both mice and guinea-pigs so as to find the bacillus in the abdominal viscera and lungs. In a case where a typhoid patient aborted in the fourth month the bacillus was found in the placenta.

A CORONER ON THE MEDICAL PROFESSION.

ON the 6th inst. Mr. W. Muller, coroner, concluded an inquest at the Town Hall, Glastonbury, on the body of a man who had died somewhat suddenly and in connexion with whose illness the parish doctor, Mr. J. A. Bright, had been accused of neglect. After the evidence of deceased's friends had been taken, the coroner expressed the opinion that there was not the slightest justification for reflection on Mr. Bright's action, although it was very important to have rumours of this kind thoroughly sifted. Medical men were, he remarked, looked upon as "beasts of burden," and he frequently found that people were most exacting as to the work required of a medical man. The jury returned a verdict of "Death from natural causes, probably syncope, or failure of the heart's action."

REMEDIES FOR PROFESSIONAL OVERCROWDING IN BELGIUM.

OUR Belgian *confrères* keep lamenting the overcrowding and the consequent poverty of the profession, and various propositions are brought forward in the medical journals for improving matters. The scheme for obtaining colonial surgeoncies in Algeria having been shown to be impossible, it is now suggested that Belgian practitioners should emigrate to Canada, the United States, Brazil, Australia, the north of Italy, and especially to the Dutch Indies, about which last colony some information is given. It appears that in order to obtain an appointment from the Dutch Government it is not necessary to be a Dutchman. Candidates must be qualified to practise in their own country; they must be under thirty-five years of age and unmarried, and must know German, Flemish, or Dutch. They must be physically suitable for military service in the Indies, and must pass a very short *vivâ voce* examination. Applications have to be addressed to the Colonial Department, the Hague. The emoluments are a bonus of £320 and an allowance at the rate of £112 a year until embarkation; after landing the salary is £288, with an allowance of £29 for forage. On return to Europe after an absence of five years a bonus of £160 is given. In addition to Government pay, private practice is allowed. In Batavia, where new-comers are usually sent, the medical men and lawyers are said always to try to establish themselves near the Chinese quarter, the Celestials paying good fees; the Arabs having, on the other hand, the character of being very parsimonious, while the Europeans, it is reported, scarcely ever pay at all! Another writer, looking to the condition of the profession in Belgium, suggests three main reforms as imperatively required in order to save practitioners from impending destitution: (1) that pharmacists should be forbidden to supply medicines, except on a prescription from a medical man; (2) that proprietary and patent medicines should no longer be sold; and (3) that quacks should be put down. He also thinks that the examinations should be made more stringent, so as to reduce the number of men entering the profession in the future. It is thought by some persons in this country that all our own professional troubles and difficulties would disappear as if by magic if we were to adopt the continental system of non-dispensing practice; but this and a good deal more which is constantly appearing in foreign journals show pretty plainly that our low fees and other troubles are not due merely to the system of practitioners dispensing their own medicines.

INTESTINAL DISPLACEMENT A CAUSE OF DYSPEPSIA.

M. GLÉNARD, a Vichy physician, believing that displacements of the intestine or "enteroptoses" are a good deal more frequent than is generally supposed, and that they are, indeed, a common cause of dyspepsia, has been in the habit of examining the dyspeptic and neurotic patients who consult him by making them stand up, and then going behind them and pressing on the abdominal wall when in a relaxed condition. If this produces a distinct alleviation of the discomfort he considers that enteroptosis is present, and orders a binder, which in these cases gives great relief, only lasting, however, while it is actually worn. A discussion on this subject has just taken place at a meeting of a Paris Medical Society, but M. Glénard did not find many of his colleagues prepared to accept his views.

AN ANTIDOTE FOR ARSENIC AND ACONITE.

IN a recent number of the *Indian Statesman* there appears a communication from Syed Walayet Ali Khan, of Patna, Bengal, on a specific antidote for poisoning by arsenic and aconite. It is described as being the bark of the common goolar tree, generally known to Europeans as the Indian fig. It is administered in doses of from ten to twelve drachms, ground fine, and mixed with water. In severe cases it may be necessary to repeat it at short intervals three or four times, but it is said never to fail. It has been found successful, according to the author of this statement, in every case in which it has been tried. We have consulted Dymock's "Vegetable Materia Medica of Western India," Waring's "Bibliotheca Therapeutica," and other works, but can find no reference to its use for this purpose. It seems strange that it should be an antidote both for arsenic and aconite, as these drugs do not produce the same symptoms, and are not allied physiologically. The matter requires further investigation, and we must admit that we are at present sceptical as to its value.

EXISTENCE OF THE CANAL OF PETIT QUESTIONED.

M. CLAEYS has communicated to the Royal Academy of Medicine of Belgium an account of some elaborate researches he has been making, with the help of all the most improved methods of microscopical manipulation, on the anatomy of the eye, and especially on the construction and attachments of the ciliary ligament. The canal of Petit, he believes, does not exist.

"UNMUZZLED."

SIR CHARLES WARREN'S well-written article on "Dogs in London" must have chagrined the hysterical and depressed the sentimental. We have already doubted the advisability of abrogating the police order just now; but we are pleased to read that Sir Charles recognises the possibility of the necessity for an early renewal of the really merciful and not seriously inconvenient muzzle. We go a step further, and urge its immediate replacement, not only on all London but all provincial dogs. Evidence is forthcoming to show that rabies is rife in the immediate and remote environments of the metropolis. Why should London wait until more dogs and other human victims are sacrificed to the dire disease?

THE QUEEN'S JUBILEE HOSPITAL.

WE are actually threatened with another hospital, as if we had not too many already, and the existing ones had a superfluity of support. As we have said elsewhere, the Jubilee of the Queen may not be without bearing on our hospitals. But we respectfully advise Her Gracious Majesty and all her subjects to have regard to existing institutions, and to those great general Hospitals which have so nobly earned a claim to generosity and consideration.

VACCINE SHIELDS.

WE have been asked to call attention to a new form of vaccine shield. It consists of a piece of spongio-piline, in which is cut a circular hole covered over with transparent goldbeater's skin; to one side of the spongio-piline is added a layer of adhesive mixture, to enable it to be fixed to the arm, so that the vesicles are situated in the central hole, and are surrounded by the spongio-piline. We are unable to recommend its use. In the first place, shields are not required; and in the second, they readily become soiled, and thus potent for septic mischief. Shields, however cheap, in the hands of the poor are frequently lent from one to another, and it is a common experience that they are a constant source of mischief. We may remind our readers that not long since the medical officer of the Local Government Board directed public attention to the dangers attendant upon their use.

SCHOOL SANITATION.

A GENERAL MEETING of the Medical Officers of Schools Association was held in the rooms of the Medical Society on Tuesday, Jan. 11th. The President (W. S. Savory, Esq., F.R.S.) occupied the chair. A paper was read by Mr. Charles E. Paget, medical officer of health for Westmoreland, on the "Arrangement and Construction of School Sanatoria for Infectious Diseases." The paper, which dealt clearly and exhaustively with the subject, and which included a description of some novel and ingenious details of construction, gave rise to a full discussion; and a general opinion was expressed that the public, no less than school authorities, would derive benefit from a more intimate acquaintance with the necessities and the claims of this important branch of school sanitation.

UNIVERSITY OF LONDON.

CONVOCATION will meet on Tuesday next, the 18th inst. at 5 P.M., when Sir Philip Magnus will present a report from the sub-committee for reconstituting the University, and will move its adoption. The Annual Committee will suggest to Convocation the acceptance of "Spiritus intus alit" as the motto for the University. There is no further matter affecting the medical graduates on the agenda paper.

NEW MEDICAL CORPORATION IN SPAIN.

A NEW "college" or medical corporation for the promotion of the study of the medical sciences, from both a practical and a theoretical point of view, as well as for the promotion and protection of professional interests, has been established at Lerida in Spain. It is entitled El Colegio Médico Quirurgico de Lérida.

GENERAL MEDICAL COUNCIL.

PROFESSOR BELL PETTIGREW, LL.D., F.R.S., Dean of the Medical Faculty, has been appointed by the Senatus Academicus to represent the University of St. Andrews at the General Council of Medical Education and Registration of the United Kingdom for a period of five years.

Our Dublin correspondent telegraphs that Sir George Porter, Surgeon-in-Ordinary to Her Majesty in Ireland, has been offered and has declined the post of Crown Nominee for Ireland on the General Medical Council.

THE PATHOLOGICAL SOCIETY.

AT the meeting of the Society on Tuesday next the newly elected President, Sir James Paget, Bart., will deliver an address on taking the chair.

FOREIGN UNIVERSITY INTELLIGENCE.

Lyons.—M. Berne, professor of external pathology, has been obliged by ill health to obtain leave of absence during the present academical year.

Paris.—The candidates for the Chair of Internal Pathology vacated by M. Peter on his appointment to the Professorship of Clinical Medicine at the Hôpital Necker, were MM. Debove, Dieulafoy, Duguet, Joffroy, Lancereaux, Landouzy, Quinquand and Strauss. From these the faculty has selected (1st) M. Dieulafoy, (2nd) M. Strauss, and (3rd) M. Dugu

Digitized by Google

The selections for the Professorship of Anatomy are (1st) M. Farabeuf and (2nd) M. Rémy; and those for the Chair of Physics are (1st) M. Gariel and (2nd) M. Desplats. A new professorship, the chair of which will be filled by Dr. Dubuisson, is about to be established at the School of Law. He will treat of "Mental Maladies" from the point of view of the legal responsibility of criminals affected in their mind.

St. Petersburg.—Prof. Sorokin's term of office has been prolonged for a period of five years.

Odessa.—After a good deal of delay and uncertainty about the establishment of a medical faculty, the Town Council has decided to grant the sum of £900, which is required to enable the university architect to visit and inspect foreign buildings of a similar nature, and to prepare the plans, on the express condition, however, that the Russian Government will promise definitely to authorise the establishment of the proposed medical faculty.

On the 5th inst. the death occurred at Bournemouth of Colonel Sir Francis Bolton, who since 1871 had been the examiner under the Board of Trade of the water-supply of the metropolis. The deceased, who was born in 1831, had for some time past suffered acutely and undergone several operations, which, however, unfortunately proved unavailing to prolong what was undoubtedly a useful life.

THE total number of students in the medical faculties of the German universities is about 300 in excess of what it was last winter session, the largest increase (seventy-six) being at Würzburg. Berlin shows a decrease of eight, and Königsberg a decrease of four.

ANOTHER extensive outbreak of measles is reported. The village affected is called Sebastopol, Monmouthshire, and over 100 children have already sickened. Efforts are being made to stay the spread of the infection by means of school-closing and other precautions.

THE Faculty of Medicine of Paris has conferred the Lacaze Prize of 10,000 fr., awarded every four years for the best work on the treatment of fevers, typhoid in particular, to M. Albert Robin, for his "Leçons de Clinique et de Thérapeutique Médicales."

AT a recent open competition for two colonial surgeoncies in the Phillipines held in Madrid, more than thirty practitioners presented themselves as candidates, several of them evincing, as the Spanish medical press states, proofs of exceptional merit.

A MEETING of the delegates appointed by the Boards of the various Medical Schools to confer on the question of degrees for London medical students will be held to-day (Saturday), at 4 P.M., in the Board-room of the Middlesex Hospital.

CHOLERA is evidently extending in Chili, the disease having appeared at several points in the coast province of Valparaiso, where within the past few days seventy cases and twenty deaths have been recorded.

PROFESSOR ARTHUR GAMGEE, M.D., F.R.S., will begin a course of eleven lecture, on the Function of Respiration on Tuesday, the 18th inst., at the Royal Institution.

THE Commissioners of Sewers have resolved to expend £2300 in sinking wells to supply artisans' dwellings at the east-end of the city with water.

The Lancet Sanitary Commission.

THE SANITARY CONDITION OF ROCHESTER.

No. II.

OTHER local improvements than those we have enumerated deserve recognition. A considerable expense has been incurred to prevent the inundation of that part of Strood which is below high water spring-tide; a well-constructed embankment now protects this part of the district from the flood which had previously detracted from its healthiness. Again, a hospital for infectious disease has been erected, and accommodation thereby provided for the isolation of persons suffering from infectious disease, as well as an ambulance for their removal. But Dr. de Chaumont recently reported the hospital accommodation to be insufficient. At this institution also is the necessary apparatus for the disinfection of clothing and bedding which require this treatment. If the Sanitary Authority of Rochester may therefore claim in several respects to have shown some diligence in protecting the inhabitants of their district against disease, in other respects they have been grievously negligent; and the chief failing, as already pointed out, relates to the existence of cesspools for the retention of excremental filth throughout practically the whole of the district. We have thought it would be well to consider this subject more in detail, and have therefore directed our attention to certain special localities. In these places, we regret to say, we have found houses the condition of which is simply deplorable, and where the cesspool system gives rise to nuisance which should not be tolerated by any authority claiming to do its duty.

Turning out of King-street is Benster-court, in which are situated nine houses; the court is unpaved, and, as a result, the ground is more or less sodden at times of rainfall. Four are small brick houses, each consisting of two rooms of a cubic capacity of 630 ft. In one of these houses live a father, mother, and five children. In this house the family complained of the dampness, and the plaster and floor are broken in places. Opposite these houses, a little over twenty feet distant, is an offensive privy in connexion with a cesspool, and adjoining is a washhouse, the roof and walls of which are broken in, rendering it absolutely unusable. In only one of these four houses are the windows not broken. Another house in the court is in a condition absolutely unfit for human habitation; it appears to have been originally simply a wooden structure; the walls have, however, been partially covered with cement, as if with the object of keeping out the wet, but the cement is broken, and the interior of the house presents a melancholy spectacle. The house is dirty to a degree, and the plaster crumbling; holes in the walls admit but too freely the cold air and wet, in spite of the efforts made to stuff them with flock. The window-sashes have perished, the windows are broken, and the interior woodwork generally rotten. The remaining houses are in better condition, but two of them are but eleven feet distant from another offensive privy, which further serves to pollute the air. Adjoining is a house in King-street, having an unpaved and apparently undrained yard, for the rain percolates beneath the house, and renders it so damp that the inmates complain bitterly of its condition. There is no dustbin; the household refuse is thrown on the ground; and, again, a similar offensive privy and cesspool only ten feet from the house send their emanations into its open windows.

In close proximity to this court is Kettle-court. This place is very imperfectly paved, and the damp easily finds access to the houses. One of them is in wretched repair; the plaster is crumbling, the floor broken, and the paper on the walls hanging in shreds. This is indeed no wonder, for the windows are broken, and the window-sashes so rotten that it is almost impossible to make them hold the glass. The inhabitants complain strongly of the offensive odours which emanate from a privy and cesspool only eleven feet distant, and evidently not without cause. The inmates of another house complain of the offensive cesspool and privy at the rear of a house in King-street, from which they are but ten feet distant. The mother of the family in the King-

Digitized by Google

street house describes the smells as terrible; she states that her husband and children have never been well since they entered the house, suffering from sore-throat, headache, and loss of appetite; moreover, she told the story how on one occasion the wainscoting of the back room of the house gave way, and how through the opening they could see into the cesspool, from which swarms of flies entered the house.

In another part of the town is Ironmonger-lane, where the same arrangements for the retention of filth exist. In an unpaved yard is a large cesspool, which the inhabitants state contains two large cart-loads of filth; this cesspool is in communication with some privies, which stink abominably, and which are almost choked with excreta. Ineffectually covering it is a paving-stone, but the stone is loose and the odours freely mingle with the air. The residents in the court state they can scarcely live here at all in the summer, one woman remarking that at night she was frequently compelled to get out of bed on account of the stench which found its way into her house. For the whole of this court there is no dustbin, the refuse lies piled in a corner, and the washings add to the offensiveness of the soil.

In another court—Nye's Cottages—where there are ten two-roomed houses, the ground is unpaved, the rain-water from the roofs has to traverse a considerable distance before it can find its way to a gully, there is no dustbin, and the house ashes are used for filling up holes in the yard. In the centre is a large cesspool, in connexion with which are four privies, two of which at the time of our visit were almost choked with excreta. The stench from these places can be better imagined than described. As one woman said, "they smell wonderful; in summer, if you only go inside, you come out and retch your very inside out." The cottages are more or less damp; in one which was entered the paper was separating from the walls, although we were told it had only been renewed last April. Here, too, the flooring was broken and the window-sashes were decayed.

Other houses in King-street must be equally condemned. Of four we inspected, in one the plaster in the basement was found to be dropping, and, owing to the flooring being lower than the level of the court behind, the surface water freely entered. Behind it, and but a few feet distant, is a privy, which we were told "smells very badly; smells come in horrid at back windows." In another, owing to a defective roof, the water simply pours into the back room at the top of the house; thence it runs to the back room on the ground floor, and then to the corresponding room in the basement, where the plaster of the ceiling is crumbling. These rooms are not occupied by the family living in the house, nor could they be occupied, for they are unfit for human habitation. The family here also complain of the stink from a privy and surface drain in the rear of the house. This drain apparently empties itself into an adjoining cesspool, and its mouth is merely protected by an ordinary bell-trap. In a fourth house the inmates receive their water from a private well situated in the back yard, which also supplies water to an adjoining house. Within a few feet of it is a cesspool receiving washing water and the water used for the boiling of tripe. At the time of our visit the cesspool was overflowing, and its liquid contents had reached to within seven feet of the edge of the well.

It is needless to multiply these instances further, but they serve well to show the deplorable condition to which a town is brought that does not provide itself with adequate means of drainage. There is obviously but one effectual remedy—the adoption of a sewerage system and the abolition of all cesspools. But this is not all. The sanitary authority are armed with ample means for compelling landlords to maintain houses in habitable condition, and no possible excuse can be found for the state in which many houses in the Rochester urban district are at the present time. For many of the defects such as we have described, the Artisans and Labourers' Dwellings Act, 1868, alone will afford sufficient remedy, and there is no reason why the provisions of this Act should not be duly enforced.

Rochester evidently possesses a medical officer and a surveyor who are warmly interested in the sanitary condition of the town; but the estimation in which sanitary services are held by the local authority may be understood from the fact that the former of these gentlemen receives but fifty pounds a year for duties which relate to the whole urban district. There is, moreover, but one sanitary inspector, and it is obvious that his energies would be sorely taxed in any serious attempt to maintain Rochester houses and localities in proper sanitary condition. Can surprise be felt that Dr. de Chaumont has reported the administration of the Sanitary Authority to be "unsatisfactory and inefficient"? Probably the influence that is most wanted is public opinion, for officers can do little without the support of those among whom they work; but Rochester is a cathedral town, possessing a dean and resident clergy, besides many influential inhabitants. We have had experience elsewhere of the good that may come from such influences being brought to bear upon local authorities, and we would venture to submit that the conditions under which the poor and indeed all classes live have an intimate relation with their moral as well as their physical welfare, and that the neglect we have described reflects upon every resident. We would fain hope that our inspection and the sad story we are compelled to tell of Rochester may awaken a wider interest in matters which so deeply concern its population.

ABSTRACT OF ADDRESS ON

TRANSFUSION FOR HÆMORRHAGE IN MILITARY SURGERY.

Delivered at Woolwich, before the Medical Officers of the Army Medical Department, Oct. 28th, 1886.

BY CHARLES E. JENNINGS, F.R.C.S. ENG., M.S.,
ASSISTANT-SURGEON TO THE CANCER AND NORTH-WEST LONDON HOSPITALS.

GENTLEMEN,—When I accepted the kind promise of Sir Thomas Crawford to arrange for my addressing you this evening, I did so to learn rather than to teach, feeling convinced that what little information I may impart on the subject of transfusion for hæmorrhage will be more than counterbalanced by what I shall learn from you as to the applicability of the operation to the exigencies of military practice. By means of demonstrating a reliable method of transfusing blood and of proving that the simple injection into the veins of other fluids—notably saline fluid, or even water—may be safely trusted as an efficient substitute for the more complex operation, I shall be able to remove from your minds that prejudice against these therapeutic measures, which doubtless exists on account of the defective instruments, which in the past rendered the operation uncertain in its results and almost useless.

It is scarcely necessary to point out that in all cases where either transfusion of blood or intravenous injections of saline fluids is resorted to as a means of combating acute anæmia, the simultaneous or previous arrest of the hæmorrhage must be regarded as a *sine qud non*. There seems no question that saline fluids may be substituted for blood in the human subject with impunity, such substitutions not exceeding an amount which bears a definite ratio to the body weight; but if the loss of blood by hæmorrhage have exceeded this quantity (probably about one-fifth of the entire amount in the body) the transfusion of blood to restore and maintain re-animation becomes indispensable. The important fact remains that life may be jeopardised by hæmorrhage and successfully restored if fluid be injected into the veins *even after the heart has ceased to beat*, in illustration whereof I can refer to a series of experiments which I performed with a view of ascertaining the best plan of procuring resuscitation after chloroform and narcotic poisoning.[1]

The idea of endeavouring to resuscitate animals by establishing an artificial circulation after apparent death was suggested to me by the fact that in 1848,[2] at the St. Giles's Workhouse, Sir Spencer Wells (then Mr. Wells) injected saline solutions into the veins of some cholera patients there, with Mr. Bennett, who was at that time resident surgeon. Sir Spencer Wells has informed me that in one case the injection was performed with considerable difficulty upon a man apparently dead some few minutes after the heart had ceased to beat, but it was followed by a return of pulsation, warmth, and consciousness, and the patient lived for a few hours afterwards.

On Aug. 20th, 1882,[3] I injected 16 oz. of saline fluid with

[3] Ibid., p. 26.

Digitized by Google

a 3 oz. metal syringe into the veins of a patient about to die from the effects of ante-partum hæmorrhage. The cylinder of the syringe had to be detached from the nozzle and refilled several times during the procedure, the nozzle being ligatured within the median basilic vein. In this case reanimation speedily followed the saline infusion. The woman was happily delivered an hour and a half later, and recovered perfectly. The lesson here taught was that 16 oz. of saline fluid proved to be the minimum quantity necessary to restore reanimation.

On Sept. 29th, 1885, I saw a case of uterine hæmorrhage in consultation with my colleague, Mr. Elam, at Forest-gate. The patient was almost moribund, when about 22 oz. of saline fluid were injected into a vein of the arm, and reanimation immediately followed. This lady has recovered completely, and the quantity of saline fluid injected was the minimum amount necessary to effect its purpose.

Another case [4] may be cited where "22 oz. of *simple water* at a temperature of about 100° F." were injected into the veins of a woman moribund from the effects of severe uterine hæmorrhage, which occurred nine days after delivery. Mr. Coates performed the trifling operation, and reports that the result was marvellous. This patient also recovered.

I think, therefore, we are justified in maintaining that the injection into the veins of a fair quantity of fluid will satisfactorily restore reanimation in cases of very acute anæmia where other restoratives have failed, for potent restoratives had been tried and had failed in the cases quoted. The apparatus, whether syringe, irrigating-can, or syphon, designed for intravenous injection, should be one by which *more than a pint of fluid* at least can be expeditiously injected.

Though a description of my method of transfusing blood mixed with saline fluid and of replenishing the veins of the blood-giver with saline fluid, with the results of experiments upon animals, which have clearly shown the safety and utility of the method, has been published long ago, it was only in 1885 that this operation was actually performed upon the human subject.

In December, 1884, J. B——, a widower, manifested the signs and symptoms of progressive pernicious anæmia. Mr. Wm. Wickham, of Tetbury, finding his patient's condition was not ameliorated by a careful trial of the various forms of treatment ordinarily recommended for this disease, sent the patient to me at the Cancer Hospital, in the hope that benefit would accrue from the transfusion of blood. The diagnosis being carefully and accurately established, transfusion was performed on April 17th, the patient and his friends having been previously informed that only transient improvement could be expected from the introduction into the system of fresh blood in the case under consideration. About 14 oz. of blood, drawn from the giver by the apparatus illustrated in THE LANCET (1883, vol. ii., p. 365), were transfused into the left cephalic vein of the receiver, mixed with about 10 oz. of ammoniated saline fluid. About 14 oz. of saline fluid (temperature 75-80° F.) were infused into the right median basilic vein of the donor, this being the vein from which the blood was drawn. The actual transfusion and infusion of saline fluid were entirely painless both to the giver and receiver. No coagula formed in the instrument, no air was injected into the veins, and there were no signs of dyspnœa or cardiac embarrassment. The operation being completed, the man who gave the blood arose, drank a cup of tea, and walked home, a distance of four miles, without inconvenience. The wound in his arm healed quickly, and no bad effects attended the substitution of saline fluid for his blood. With regard to the receiver of the blood, a marked improvement followed the operation; but, a relapse occurring, the man died on April 24th. A necropsy made on the following day disclosed that the morbid changes were consistent with those of oligocythæmia rubra.

In conclusion, I would submit that the cases are rare where it becomes necessary to transfuse blood for acute anæmia, the intra-venous injection of a simple saline fluid, with or without the addition of ammonia or alcohol, according to circumstances, being usually sufficient to restore reanimation. The value of the addition of fresh blood lies merely in its nutritive properties, and if it be considered necessary to transfuse blood, the operation can readily be performed in the manner indicated by any surgeon with the aid of skilled assistants, as in the case, already related, of pernicious anæmia.

[We regret we are unable from lack of space to publish the discussion which followed the reading of the above paper.]

[4] *Ibid.*, p. 67.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.

WE have received the report of the Directors read at an extraordinary general meeting of proprietors and assured, held at the Society's office, Jan. 6th, 1887, on the occasion of the twelfth division of profits. The present prosperous financial position of the Clerical, Medical, and General Life Office must be very gratifying, not only to the shareholders and policyholders, but also to the directors, their actuary and secretary, Mr. Newbatt, and the staff generally. The elaborate and comprehensive report relative to its growth and successful progress is most interesting, and will help to maintain the general confidence in the Society which has lead to these exceptionally favourable results.

The Directors presented to this meeting the report of the quinquennial period which terminated on the 30th June, 1886, and the result of the investigation into the financial condition of the Society at that date.

Dealing with the transactions of the five years, the following facts present themselves: The new assurances—2706 in number, assuring £1,759,771 and yielding £59,280 in annual premiums—were larger by £157,903 in amount assured, and produced £4415 more in premiums, than those of any former period. The yearly revenue progressed in an increased ratio, and reached £316,164 in 1886, as against £286,512 in 1881. Of the total increase of £29,652 here shown, £16,825 arose from premiums and £12,827 from interest. The interest earned during the quinquennium on the whole of the funds, whether invested or uninvested, was at the average rate of £4 2*s.* 2*d.* per cent. per annum, as compared with £4 3*s.* 11*d.* per cent. in the previous five years. Having regard to the continuous decline in the value of money during the period under review, and to the fact that the integrity of the Society's calculations will be maintained by a net earning of 3 per cent., the rate thus actually realised is highly satisfactory. The claims by death were 947 in number and £812,127 in amount. Though both larger and more numerous than in the previous five years, when they amounted to £739,684 on 886 lives, they fell short of those expected by 268 in number and £283,441 in amount. They were, moreover, exceptionally profitable in character, owing to their having fallen on older policies held on older lives. The total expenses, in spite of the growing cost of obtaining new business and of the much larger new business which was secured, were again moderate and well within the provision made for them in the premiums. They were practically identical with those of the last quinquennium when compared with the total revenue, and were but fractionally higher—11·75 per cent., against 11·49 per cent.—when taken as a percentage on the premium income alone. The Assurance Fund, thus favourably affected both by income and expenditure, rose from £2,433,398 in 1881 to £2,715,760 in 1886.

It is stated that the total assurances subsisting on June 30th last were 10,531 in number, assuring, with their bonus additions, the sum of £6,849,646, as compared with 9925 policies, for £6,345,374, in 1881. These assurances, and annuities for £2650 per annum, constituting together the whole of the engagements of the Society, have been the subject of the present investigation.

The value of the assets of the Society being a matter of no less importance than that of the obligations which they have to meet, the securities have all undergone the usual careful examination by the directors. As has been seen, the Assurance Fund on the 30th June amounted to £2,715,760.

Particulars of the valuation, as well as of the various assets of the Society, are set out in detail in annexed schedules, prepared for the Board of Trade pursuant to the

Digitized by Google

Life Assurance Companies Act 1870. From these it will be seen that

The Assurance Fund on June 30th having been	£2,715,759 13 6
And the calculated liability at the same date	2,232,586 8 8
There was a surplus of	£483,173 4 10

Deducting from the last-named sum the Permanent Reserve of £50,000 required to be set aside by Section 32 of the Society's special Act of Parliament, the net surplus becomes £433,173 4*s.* 10*d.*

This surplus is larger by £66,479 5*s.* 5*d.* than any heretofore exhibited.

In furtherance of this policy, which will at once protect the interests of existing members and render the Society additionally attractive to future assurers, the directors propose now to divide £375,000, a sum larger by £30,000 than that divided in 1882 and sufficient to give to the proprietors £12 10*s.* a share, and to the assured the largest cash distribution ever allotted to them, leaving the balance of £58,173 4*s.* 10*d.* to fall back into the Assurance Fund as undivided surplus. This amount thus divided, £312,500, will fall to the assured, yielding a cash bonus averaging 33⅓ per cent.

POOR-LAW INFIRMARIES.

AT the adjourned meeting of the medical superintendents of Poor-law infirmaries held at St. George's Union Infirmary, Fulham-road, on Dec. 18th, 1886, Dr. Lloyd in the chair, the following resolutions were adopted:—

Moved by Dr. Spicer and seconded by Dr. Neal: 1. That it is desirable that the medical superintendents of the metropolitan infirmaries be authorised to call into consultation a specialist of eminence, when the circumstances of any case under their charge may be deemed by them to render such a course advisable. 2. That it is desirable such consultant should receive a fee in each case. 3. That any such consultant called in should be on the permanent staff of a London hospital. 4. To advise in the treatment of cases, and only when they have been called upon to; do so by the medical superintendents.—Moved by Dr. Webster and seconded by Mr. Lunn: 5. That it is desirable, in view of the large amount of clinical material in the metropolitan infirmaries, both in the interests of the patients and of medical science, that one or more qualified clinical assistants be appointed in each infirmary, in addition to the present medical staff.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6090 births and 4690 deaths were registered during the week ending Jan. 8th. The annual death-rate in these towns, which had been equal to 20·7, 21·5, and 25·1 per 1000 in the preceding three weeks, further rose last week to 26·5. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·3 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 15·7 in Sunderland, 17·2 in Derby, 18·4 in Nottingham, and 18·5 in Brighton. The rates in the other towns ranged upwards to 33·2 in Newcastle-upon-Tyne, 34·0 in Leeds, 36·4 in Manchester, and 40·6 in Plymouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 386, 433, and 537 in the preceding three weeks, declined again last week to 475; they included 235 from measles, 81 from whooping-cough, 63 from scarlet fever, 47 from "fever" (principally enteric), 28 from diarrhœa, 21 from diphtheria, and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Nottingham, Brighton, and Leicester; and the highest death-rates in Manchester, Bristol, Leeds, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Liverpool, Manchester, Newcastle-upon-Tyne, and Leeds; from scarlet fever in Norwich, Liverpool, and Bristol; from whooping-cough in Bristol, Manchester, Oldham, and Plymouth; and from "fever" in Liverpool and Preston. The 21 deaths from diphtheria in the twenty-eight towns included 9 in London, 2 in Bristol, 2 in Manchester, and 2 in Preston. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 416, 436, and 573 in the preceding three weeks, further rose last week to 731, and exceeded the corrected average by 221. The causes of 120, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Portsmouth, and Derby. The largest proportions of uncertified deaths were registered in Oldham, Preston, Sheffield and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 26·2 and 25·1 per 1000 in the preceding two weeks, rose to 29·9 in the week ending Jan. 8th; this rate exceeded by 3·4 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·7 and 21·1 in Leith and Perth, to 35·0 in Glasgow and 40·2 in Paisley. The 746 deaths in the eight towns last week showed an increase of 111 upon the number in the previous week, and included 27 which were referred to whooping-cough, 18 to diarrhœa, 17 to measles, 13 to scarlet fever, 12 to diphtheria, 7 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all 94 deaths resulted from these principal zymotic diseases, against 63 and 73 in the preceding two weeks. These 94 deaths were equal to an annual rate of 3·8 per 1000, which was 1·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 15 and 21 in the preceding two weeks, further rose last week to 27, which included 18 in Glasgow, 3 in Edinburgh, and 3 in Paisley. The 18 deaths attributed to diarrhœa showed a further increase upon recent weekly numbers; 10 occurred in Glasgow and 3 in Edinburgh. The 17 fatal cases of measles also showed an increase upon the numbers in recent weeks, 16 being recorded in Glasgow. The deaths from scarlet fever, which had been 13 and 12 in the previous two weeks, rose again last week to 13, of which 9 occurred in Glasgow and 3 in Edinburgh. The 12 fatal cases of diphtheria (only one had been returned in the previous week) included 7 in Glasgow and 4 in Edinburgh. The 7 deaths referred to "fever" showed a decline of 3 from the number in the previous week; 3 were returned in Aberdeen and 2 in Glasgow. The deaths from acute diseases of the respiratory organs in the eight towns, which had been 188 and 179 in the preceding two weeks, rose last week to 213, and exceeded the number in the corresponding week of last year by 81. The causes of 98, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·6, 28·5, and 38·0 in the preceding three weeks, declined again to 31·3 in the week ending Jan. 8th. During the thirteen weeks of last quarter the death-rate in the city averaged 26·7; the mean rate during the same period did not exceed 18·8 in London and 19·5 in Edinburgh. The 212 deaths in Dublin last week showed a decline of 45 from the number in the preceding week, and included 6 which were referred to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 3 to diarrhœa, and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had declined in the preceding four weeks from 23 to 17, further fell last week the to 13; they were equal to an annual rate of 1·9 per 1000, the rates from the same diseases being 2·1 in London and 2·8 in Edinburgh. The fatal cases of scarlet fever, which had been 6 and 11 in the preceding two weeks, declined again last week to 6; while the 4 deaths referred to "fever" corresponded with the number in the previous week. Nine inquest cases and 6 deaths from violence were registered; and 54, or rather more than a quarter, of the deaths occurred in public institutions. The deaths both of infants and of

Digitized by Google

elderly persons showed a considerable decline from the numbers returned in the previous week. The causes of 36, or nearly 17 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

"ARTERIAL PRESSURE."

To the Editors of THE LANCET.

SIRS,—If no other correspondent replies to Dr. Nicholson's letter on the above subject, you will perhaps allow me in a few sentences to suggest to him that the solution of the difficulty which he feels in reconciling the statements which he quotes from Drs. Brunton and Foster is to be found in the distinction between the *large elastic arteries* and the *terminal muscular arterioles*. The blood-pressure with tension referred to in the passage from Dr. Brunton is that which exists in the larger arteries; while, on the other hand, the constriction in the vascular area of which Dr. Foster speaks is the contraction of the muscular arterioles, the effect of which is to lessen the flow of blood through the capillaries of the particular area, and in the same degree to heighten the pressure and tension in the larger arteries which convey the blood to the contracted and resisting arterioles. It would doubtless tend to prevent misunderstanding if, in referring to parts of the vascular system, in most respects so diverse in structure and so opposed in function as the larger arteries and the arterioles, they were always designated—the first "the elastic arteries," and the latter "the muscular arterioles." The large arteries, by their elastic resiliency, aid the heart in propelling the blood onwards; while, on the other hand, the muscular arterioles, in the exercise of their regulating and so-called "stopcock" function, often antagonise the heart and the elastic arteries, and, in proportion to the degree of their contraction, resist the onward movement of the blood. The result, of course, is, as I have before said, that the contraction of the arterioles increases the fulness, tension, and pressure in the associated larger elastic arteries.

I am, Sirs, yours faithfully,

Savile-row, Jan. 8th, 1887. GEORGE JOHNSON.

THE EFFECT OF LIGATURE OF THE FEMORAL ARTERY.

To the Editors of THE LANCET.

SIRS,—I am bound to repeat that the facts, as I find them, do not appear to me to be in accordance with the views set forth by Mr. Holmes; and, further, that the difference is not an insignificant one, for it bears upon a point of practice which is suggested in the paper. Of course the artery is obliterated at the place where it is tied, and Mr. Holmes makes it clear that blood finds its way again into the artery between the ligature and the sac, and therefore that a part of that portion of the artery must remain pervious. But I submit that his description does not convey the idea that in the majority of cases the portion of artery between the clot of the ligature and the sac remains pervious throughout its whole length. This and other facts in regard to the condition of the portion of artery in question, are, I believe, made evident in the paper, to which I hope Mr. Holmes will allow me to refer him instead of taking up your space by repeating much of it here. And if I am silent on other questions raised by him in his last letter, let me assure him that it is not because I am insensible to their interest. My admiration of Mr. Holmes's surgical works, especially of his articles on aneurysm, is so great that this kind of criticism is very distasteful to me. But Mr. Holmes insists on it. I must be allowed, however, with this letter to close my part of the correspondence.

I am, Sirs, yours truly,

Brook-street, W., Jan. 10th, 1887. WM. S. SAVORY.

THE LATE PREVALENCE OF SHINGLES.

To the Editors of THE LANCET.

SIRS,—The following cases of herpes, which have lately come under my notice, present, I think, some features of interest, and may help to furnish some material towards elucidating the etiology of this disease.

A. K., male, aged forty, has been subject to herpes preputialis for the last twelve years. For about eight years previously to the year 1884 the attacks were frequent. Sometimes they occurred at intervals of only a few months, and he does not think that a year ever passed without his having one. The crop of vesicles always occurred, so far as he is aware, on the same spot on the outer aspect of the prepuce. In February of 1886 he had an outbreak of herpes on the back of his left forearm, which was preceded for several days by neuralgic pains felt in the back of the hand. In the beginning of December, 1886, he had an attack of herpes preputialis, which had not occurred for more than three years, and about ten days after this he had also an outbreak of herpes on the left forearm, the crop of vesicles being in the same place as, and resembling in every respect, the eruption which occurred the previous February.

C. K., age about sixty-seven, aunt to A. K., had an attack of herpes in November, 1886, the eruption being over the shoulder-blade and under the arm, followed by much neuralgic pain and general prostration.

The mother of C. K., when about seventy years of age, had a severe attack of herpes zoster.

In considering these cases with reference to the etiology of the disease, the following points may be noticed:—1. The manifest hereditary predisposition to this complaint, in the mother and daughter the attacks assuming the same form at about the same age. 2. The apparent influence of some causes which determine the occurrence of a number of cases at about the same time. At a time when herpes is particularly prevalent C. K. has an attack, while A. K., who may be said to be subject to this form of eruption, has a *double* attack, a thing which has never happened with him before. 3. Connexion with other diseases. Gout: No case of gout on either side of A. K.'s family. Rheumatism: There seems to be almost as little tendency to this complaint, the only case in the family being that of a sister of C. K., a lady of seventy years of age, who has been troubled with rheumatism for the last few years. Scrofula. On the other hand, there is a distinct connexion with this disease. A. K. has had glandular abscesses in the neck. C. K. has had diseased bone in the foot, and suffers from lupus. 4. As to the immediate predisposing cause: A. K. has not been able to connect his attacks with a chill, although he has taken notice of this, his attention having been drawn to this point. He has always connected an attack of herpes with some change in his general state of health, always feeling in better health and spirits after the attack than immediately before. 5. The case of A. K. shows the tendency of herpes, in those instances in which it recurs, to appear in the same situations.

I am, Sirs, yours obediently,

A. W. HARDING, B.A., M.B. Lond.

Ealing, W., Jan. 11th, 1887.

A "NEW" METHOD OF EXCISING THE KNEE-JOINT.

To the Editors of THE LANCET.

SIRS,—Mr. Allingham, in saying that he "was fully aware that Professor Ollier suggested" the operation, scarcely does that surgeon complete justice. He had minutely described it and definitely given his views of the indications for its use. Even in 1883 he had evidently practised it on the dead subject. His description of it is most precise and detailed, and occupies two pages, one of them small print, of the *Revue de Chirurgie*. If, in spite of his great opportunities, he has really not yet done it on the living, it must be because he considers it suitable for only a very narrow range of cases. It is not quite clear whether Mr. Allingham mentions his inability to find a report of my case as a defence for himself or as a reproach to me. If the former, I do not grudge him any defence; if the latter, I reply that when I found I had been anticipated by Ollier, whose article on the subject had even been noticed in your own columns, and that I had nothing to add to his remarks, I was content

Digitized by Google

to exhibit my patient without writing about him. But the third edition of my Index of Surgery contained the following sentence: "Ollier, when resecting for injury, makes a longitudinal incision and saws longitudinally through the patella." When I confess to this reticence, I feel more as if I were boasting than acknowledging anything to be ashamed of. My operation was done on a boy, aged sixteen, on Sept. 11th, 1883, and the following extract is from the notes of Mr. H. H. Taylor, then house surgeon at the West London, now at Brompton Hospital: "Under ether, and antiseptically, a longitudinal incision was made over the joint. The patella was sawn through in the same direction. ..... The patella was wired." I thought at the time that I had done something new, and I should be the last person to reproach Mr. Herbert Allingham for making the same mistake. I have made it a rule to avoid wasting my time in contesting claims of priority, and should perhaps have not begun this correspondence if I did not strongly disagree with Mr. Allingham's estimate of the value of the procedure, which it would now be a graceful act of his to join me in naming "Ollier's." The mistake of crediting your journal with a report which did appear in a contemporary is surely of no significance. With your kind permission, I will, at an early date, publish in your columns a briefly reported series of erasions and excisions of the knee-joint, including the case just mentioned, and then state more fully than I can in this correspondence what experience has taught me about the choice of methods. I remain, Sirs, yours obediently,

Jan. 1887. C. B. KEETLEY.

REMOVAL OF THE UTERINE APPENDAGES.

To the Editors of THE LANCET.

SIRS,—It is only just now that I have seen the report published in THE LANCET for Jan. 1st, of the Leeds and West Riding Medico-Chirurgical Society's November meeting, in which Mr. W. H. Brown is stated to have read notes of a case of removal of the uterine appendages under circumstances calling forth the unanimous condemnation of subsequent speakers. Had I noticed the record sooner I should have lost no time in asking to be allowed to remove the responsibility from Mr. Brown's shoulders to my own, inasmuch as the operation was mine, and Mr. Brown had obtained my full permission to relate the case at the Society's meeting. Unfortunately I was not present that evening, or the remarks which I should have had the opportunity of making might possibly have materially modified the criticisms and consequently the report, which, as it stands in your columns, must convey the impression that Mr. Brown has been guilty of performing an unnecessary and an unjustifiable operation. Moreover—although I am sure Mr. Mayo Robson, who, as secretary, is, I believe, responsible for the published abstract, had no desire to suggest that the operation had been undertaken without consultation—the stress he lays upon his own practice of always having a full consultation (whatever that may mean) before operating will lead many to the erroneous conclusion that in this case so necessary a precautionary measure had been omitted.

I am not concerned at present to discuss the ethics of pelvic surgery. I will only say on that point that, under precisely similar conditions, I should again act exactly as I did in this particular instance; and it may not be superfluous to add that in the case related by Mr. Brown, although as the operator I am prepared to assume my full share of responsibility, no fewer than three unanimous consultations were held with my colleagues, among whom are Mr. Wheelhouse and Mr. Mayo Robson, as well as Mr. Brown.

I am, Sirs, very faithfully yours,

Leeds, Jan. 8th, 1887. T. R. JESSOP.

ALCOHOL AS MEDICINE.

To the Editors of THE LANCET.

SIRS,—A recent remarkable County Court trial has attained a wide publicity. The widow of a member of a Phœnix total abstinence society brought an action against the society for the amount of death claim due on her late husband's decease. The society's defence was that the man had broken his total abstinence pledge (the Phœnix insisting on absolute abstinence without medical exception) by taking some intoxicating wine ordered by his medical attendant. The judge was most righteously indignant at this truly infamous defence, but was compelled to yield to the defence on the ground that the man himself on his sick bed had accepted the return of his subscription and his exclusion from benefit.

On inquiry I am happy to find that this is an isolated society, and is not one of the great Phœnix orders, leaders of which general bodies assure me that their action in such *bonâ-fide* circumstances would have been to pay the widow's claim. We all know the false medical pretences on which people are apt to father their teetotal pledge breaking, and also the loose way in which alcoholic intoxicants are sometimes ordered; but it ought to be thoroughly understood that the temperance cause is not responsible for such shocking, disgraceful, and unjust treatment of a man on his death-bed and his widow in her sorrow.

I am, Sirs, your obedient servant,

Grove-road, N.W., Jan. 8th, 1887. NORMAN KERR, M.D.

*** For the correct name of the particular "Lodge" see an Annotation on p. 139.—ED. L.

PROMOTION IN THE ARMY MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—Referring to your remarks regarding the Army Medical Service, will you permit me to say that your original comment, to the effect that a medical officer could not, by regulation, be promoted to the rank of Brigade Surgeon without having passed the required examination, was, in my opinion, perfectly correct, and your correspondent who took exception thereto wrong. If you will turn to those regulations, you will find that he has, notwithstanding the use of inverted commas, made an important omission. The words are not "promoted for distinguished service," but "medical officers of any grade promoted for distinguished professional service will be exempt from further examination." Moreover, paragraph 8 of the same regulations is that which is applicable to such a case, and it seems clear and specific enough. It runs: "He must, before he can be selected for promotion to the grade of Brigade Surgeon, establish before an examining board, appointed for the purpose by the Director-General, his efficiency in the following subjects"—viz., those of the examination.

I am, Sirs, yours truly,

Jan. 10th, 1887. A MEDICAL OFFICER.

FRIENDLY SOCIETIES' MEDICAL ASSOCIATIONS AND THEIR INJURY TO MEDICAL PRACTICE.

To the Editors of THE LANCET.

SIRS,—Having seen several letters in your valuable paper, complaining of the difficulty of qualified men getting work to do, and the replies stating that it was greatly owing to the employment of unqualified assistants, I must in justice say that I consider it is more due to the springing up of late years of amalgamations of clubs called "friendly societies' associations," and on which head I have a right to speak, having unfortunately for many years been connected myself with one until lately, where the payments of the members and their wives are four shillings, and of children under eighteen two shillings a year, for which small amount visits and medicine are included, and patients seen within a radius of three miles. I do not believe there are any provident dispensaries conducted at so low a rate of payment. We certainly had the honour to have two town councillors, and I do not believe I shall be wrong if I say three belonging to us, also some of their wives and children, all of whom derived the benefits of the association at the same magnificent scale of payment. There were numerous other members in good stations of life in the like category. The secretary, a paid official, an officer under the Local Government Board, also allowed his family to partake of the benefits of the society. The association numbered nearly 4000 members, and to visit, dispense, and attend midwifery there was the large staff of two medical officers, who did not get half the annual receipts or any augmentation of income from increase of members.

All I can say in conclusion is, that I warn young medical men from taking up such appointments, as they lower the

Digitized by Google

status of the profession; and if the salary seems good, it is more than counterbalanced by the enormous amount of work expected and by the insults received.

I am, Sirs, yours faithfully,

Dec. 28th, 1886. SURGEON.

SUPPURATION IN THE APPENDIX VERMIFORMIS.

To the Editors of THE LANCET.

SIRS,—With regard to the query contained in the last sentence of Mr. Barford's communication to you on his most interesting case, I think there can be only one answer, and that is to remove by abdominal section the purulent appendix, and drain the abdominal cavity. Sufficient cases have been put on record to attest the wisdom of trusting to timely and bold surgery such as I suggest, rather than to opium or other medicaments.

I am, Sirs, yours truly,

Nottingham, Jan. 9th, 1887. GEORGE ELDER.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE THROAT AND EAR HOSPITAL.

THE annual meeting of this charity was held to-day, the Sheriff of Newcastle, W. H. Stephenson, Esq., presiding. The number of patients entered for the first time was 1482, while 546 remained on the books from 1885, making in all 2028 cases treated during the year. A most gratifying feature in the past year's work has been the important amount contributed by the patients, the financial statement showing that £233 10*s.* 9*d.* had been handed in by the patients to the dispenser in this way. Advice and medicine had been given 912 times free. No case is refused aid, however poor. The medical report presented the usual features of a special hospital of this nature, but the staff complain of want of room, and it has been decided to appeal to the public for aid to erect a new building. Plans, which have been prepared by Mr. J. C. Parsons, architect of this city, have been approved by the Committee, and immediate steps are to be taken to carry them into effect.

NEWCASTLE HOSPITAL SUNDAY FUND.

The final lists of the Hospital Sunday collections have been published, and show that the total amount collected at places of worship is £2119 12*s.* 5*d.*, as against £1437 5*s.* 3*d.* last year. The amount subscribed at the factories and workshops was £1770 7*s.* 1*d.*, as against £1437 5*s.* 9*d.* The amount raised is £3889 19*s.* 6*d.*, the largest figure ever reached in any year's collection. *The Newcastle Journal*, in commenting on the collection, says, "It is a satisfactory result, no doubt; but in view of the greatly enhanced requirements of the hospital charities, we cannot but feel that more will have to be done. The church and chapel collections are not likely to prove very much more elastic. They have now again very nearly touched the highest amount they have ever reached, and from which they had subsided in former years. If they can be kept up to the amount subscribed last year it will be very well, but we must trust to more liberal and better organised efforts amongst the working classes to expand the fund."

ACCIDENT TO DR. SHERWOOD OF WHITBY.

Dr. Sherwood of Whitby, well known to many in North Yorkshire and beyond as a genial and successful practitioner, had the misfortune, on Dec. 27th, to fall on leaving his surgery, and, his leg being bent under his body, he sustained a fracture of the tibia and fibula. He did not lose his presence of mind, but at once requested the attendance of the Ambulance Corps, which he had himself trained while surgeon to the local Artillery Volunteers, the members of whom, under the guidance of Dr. Tinley, removed him to his private residence, a considerable distance from the surgery where the accident befel him. It required no little care to prevent the bone in transit coming through the skin, the fracture being oblique; but so far, under the care of his friend, Dr. Tinley, he has been saved the trouble of a compound fracture, and is, I hear, doing well.

Newcastle-on-Tyne, Jan. 10th.

EDINBURGH.

(*From our own Correspondent.*)

THE ROYAL SOCIETY.

A PLEBISCITE of the Fellows was recently taken in regard to a proposal to change the hour of meeting from 8 P.M. to 4 P.M. The proposal was negatived, but the minority was so numerous that a compromise has been effected, and a series of interim meetings arranged for the afternoon hour. The first of these was held last week, and Sir Douglas Maclagan, one of the vice-presidents, presided over a gathering of some fifty of the Fellows, the numbers showing that the afternoon hour is not an impossible one, and demonstrating how wide an interest was felt in Mr. Coleman's address upon Processes of Refrigeration. In his address, Mr. Coleman covered a wide area; he dealt first with the purely scientific aspects of the subject, describing the various processes employed and quoting results obtained. Recent French and Russian observers find that atmospheric air liquefies at a temperature of −242° F.; they have also fixed the boiling points of liquid air and liquid nitrogen. Turning to the economic aspects of refrigeration, the lecturer described apparatus for continuous freezing, ether freezing machines, ammonia freezing machines, and compressed air machines. The last are in general use for the conveyance of fresh meat on board ship; they depend for their efficiency on the fact that a great fall of temperature occurs in air that is suddenly allowed to expand after compression. These machines maintain a temperature of from 10° to 20° below freezing point, at which meat can be kept good for an indefinite period. Over two million frozen carcases of sheep have been brought to this country, chiefly from New Zealand and South America. Interesting results, which are quite new, also accrued to some experiments made by Mr. Coleman and Prof. McKendrick as to the influence of cold upon the vitality of micro-organisms. They found that vitality was retained and activity regained by organisms that had been exposed to a temperature of −120° F. for 100 hours. Prof. McKendrick, speaking at the end of the address, said that, much as had been done in developing refrigerating processes, there was still great room for further important advances fraught with great scientific interest and practical benefit.

POLICE CASES AND THE DUTY OF MEDICAL MEN.

A recent homicide by stabbing in a public street in Edinburgh has created some discussion as to medical responsibility in police cases. A week ago, a man was severely stabbed in the region of the chest, whilst quarrelling, in the presence of several bystanders. He was found by his friends to be seriously injured. It is stated that they applied for aid at the houses of two medical men in the neighbourhood. In each case they were told to take the sufferer to the Royal Infirmary. They did so, and upon arriving there he was found to be dead. Some important letters on the subject have appeared in the local newspapers. On the one hand, it is urged that the doctors have been guilty of inhumane conduct in declining to attend the case; on the other, that, leaving out of account the extreme ambiguity of the term "doctor" in the district in question, where herbalists and others receive that courtesy title, the public have only themselves to blame if they find a medical man unwilling to hasten at their call to patch up the victims of riotous and drunken brawls. As a rule in such cases, unless he be requested to attend by the police authorities, a medical man is not only justified, but almost bound in self-defence, to let the injured combatants receive treatment at the police-station or the infirmary, to which they naturally gravitate. In this case the police do not seem to have made any such application, and there is no reason to believe that the medical men in question received any more urgent summons than an indistinct statement from an irresponsible individual. This occurrence has opened another important question, whether there ought not to be district police surgeons in the various wards of the city, to whom application for assistance in street accidents or emergencies might be made, without any risk of attendance being refused. This course is urged upon the city authorities in an able letter by Dr. Peel Ritchie, who agitated in the same direction some years ago, and he

Digitized by Google

is supported by the opinion of several local medical men. There is cause to regret that the discussion of this proposal by the Public Health Committee has not ended in some modification of the present system, which is, that in an emergency the nearest medical man is called by the police authorities, who remunerate him for his services in accordance with a definite scale of payment. The defect in this system is that upon the police devolves the onus of deciding as to the urgency of the case, and they are naturally prone to take the view least at variance with the strict notion of economy that is very properly instilled into the force, and, as a result, mistakes are apt to occur occasionally of the nature of that now described.

EDINBURGH VITAL STATISTICS.

Dr. Littlejohn's annual report for the year 1886 has just been published. It shows a total of 4555 deaths in the year, or at the rate of 17·89 per 1000 of the estimated population. The births numbered 7457, giving a rate of 29·26 per 1000. Of infectious diseases 7623 cases had occurred, classified thus:—Measles, 5843; scarlatina, 1306; typhoid, 224; diphtheria, 212; small-pox, 26; and typhus, 12. Of these 7623 cases 380 proved fatal.

PRESENTATION.

Mr. A. G. Miller, F.R.C.S.E., Honorary Surgeon to the Royal Infirmary, and Lecturer on Surgery in the Extra-academical School, has been presented by his students with an address expressing their respect for him personally, and the high esteem in which they hold him as a teacher.

Edinburgh, Jan. 11th.

DUBLIN.

(From our own Correspondent.)

THE DUBLIN HOSPITALS COMMISSION REPORT.

ALTHOUGH the report of the Commission appointed to inquire into the condition and working of the Dublin hospitals has not yet been published, it is understood that the following recommendations are included in the report. It is suggested that the sum of money hitherto granted by the Government to the House of Industry and other hospitals in the city of Dublin should in future be distributed *pro rata* among the principal hospitals, according to their general public usefulness and the extent of their accommodation for patients. A portion of the report will refer to the system of clinical instruction and the necessity of having special wards set apart in the large hospitals for the treatment of special diseases. The Commissioners do not recommend an amalgamation of the medical staffs of certain hospitals, as was proposed by some of those examined during the inquiry. These are the chief items of interest in the report, and in addition it is believed that an effort will be made to induce the Treasury to increase the Government grant in consequence of the larger number of institutions it is proposed to have the money allocated to in future.

THE SANITARY STATE OF CORK.

A special meeting of the Public Health Committee was held last week, to consider the report lately furnished by Dr. O'Farrell, Local Government Board Inspector, in relation to the sanitary condition of the city. The first recommendation in the report was: "That the street cleansing be improved, and that a complete system of domestic scavenging be undertaken by the Corporation." It was resolved that the executive sanitary officer and other officers should prepare a report as to the best means of undertaking the domestic scavenging to its fullest extent. The next recommendation was: "That the sewers of the city be completed and modernised, and that a map be provided in accordance with the 22nd section of the Public Health Act; that all the main sewers be ventilated at their highest levels, and that they be provided with side entrances, manholes, and not less than twenty ventilators for each mile of sewer." No action was taken on this, it being understood that the map referred to would soon be completed. The third recommendation was in reference to lodging-houses and tenement-yards being kept in a sanitary condition. The fourth recommendation was that a public abattoir should be erected, but this the Committee considered to be unworkable. The other suggestions referred to the disposal of sewage, and the protection of the water-supply from contamination. The seventh and last recommendation was: "That the medical staff officer of health should devote his whole time to the duties of his office." This the Committee unanimously declined to adopt.

CORK WORKHOUSE.

Colonel Spaight (Local Government Board Inspector) in his half-yearly report on the condition of this workhouse, draws attention to the breaches of the rules, and the absence of strict discipline in the management of the institution. In reference to the system of admissions, Colonel Spaight remarks:—"I believe a very great number are admitted for treatment in the hospitals who might well pay for their maintenance. Not only are the ratepayers loudly complaining, but the accommodation in the male hospital is limited, and in such cases the beds are occupied by those who could be provided for elsewhere, to the discomfort and exclusion of those for whom they were intended. As far as I could ascertain, no question is asked or inquiry made as to the means or condition of those admitted." This is a condition of affairs which certainly should not exist, and the special committee to whom the report has been referred will, it is to be hoped, take prompt measures to rectify any irregularities which may be found to prevail.

MERCER'S HOSPITAL, DUBLIN.

I recently referred to Mr. Newcomen's exclusion from this hospital, and have now to add, in reference to the subject, that the Board of Governors, in consequence of a public investigation having been suggested by the press, lately passed a resolution requesting the Corporation to nominate three members to investigate the charges in which Mr. Newcomen is interested. This request of the governors was under the consideration of the Hospital Committee of the Corporation last week, and three members, one of whom is a medical man, were nominated to act.

NORTH DUBLIN UNION.

At a meeting of the guardians of this union last week, applications were received from the medical officers for an increase of salary. After some discussion the following resolution was passed by a large majority: "That all applications for increase of salary by the officers of this union be postponed for twelve months, in consequence of the very distressed circumstances of the union."

Dublin, Jan. 11th.

PARIS.

(From our own Correspondent.)

THE ALLEGED FAILURE IN M. PASTEUR'S INTENSIVE METHOD.

To judge by the crowded state of the public gallery at the Academy of Medicine at a recent meeting, an unusual amount of interest was taken in the discussion on the case of death from hydrophobia recently communicated by M. Peter, and mentioned in my last letter. Although the debate did not degenerate into a positive quarrel, M. Peter was interrupted frequently by protestations from more than one learned academician, and the gallery was all the time against him. Murmurs of disapprobation were heard when he hinted that the *suppressio veri* was not unknown to the directors of the anti-rabic laboratory, and the contradictions of MM. Grancher, Brouardel, and Dujardin-Beaumetz were received with applause. The discussion commenced by a statement from M. Grancher concerning the patient whose case had formed the subject of M. Peter's communication. M. Grancher said that it was affirmed by M. Peter that the patient had received thirty-six inoculations in twelve days; this was not correct, the register of the laboratory showing that nineteen inoculations only had been made, a treatment much less thorough than was necessary in bites about the face. M. Peter had insinuated that the intensive method might give rise to accidents, a possibility which the partisans of the inoculations were perfectly prepared to accept, and with which every new therapeutic method is obliged to reckon. Each of the rare failures brings its lesson, and it would seem that alcoholism, the nervous temperament, and epilepsy are unfavourable, whereas youth is a favourable condition for the treatment. The treatment was now graduated for each patient by taking into consideration the special risks resulting from the bite, and the special susceptibility of the individual. M. Brouardel

Digitized by Google

said that allusion had been made in M. Peter's communication to a child who was said to have died of hydrophobia. This child had been bitten on Oct. 8th by a stray dog. Inoculations were made from the 20th and lasted twelve days. On Nov. 23rd the child was struck by one of his playmates in the loins. He fell ill thirty-six hours later, and died the following day in collapse, with diaphragmatic spasms; there had been no "hydrophobia," but there had been an impossibility to swallow liquids. In this case, the post-mortem examination showed symmetrical ecchymoses at the back of the kidneys, and the urine contained albumen. The inoculation of two rabbits with the child's medulla did not give rise to rabies. The child had, no doubt, died of uræmic poisoning due to albuminuria. M. Dujardin-Beaumetz related his investigation into the case under dispute. His communication threw no light upon the subject. M. Peter's facts do not seem to have been contested, and it is of no interest to record the opposite judgments passed upon them by different observers. M. Peter, in reply, said that he had felt compelled to make known the case related by him to the Academy on account of the danger of the new intensive method, and of the secrecy with which all the deaths following upon it were concealed by the persons concerned. As long as M. Pasteur had confined himself to his first method of treatment, he (M. Peter) had merely looked upon it as inefficacious; but since the modified plan had been adopted the inoculations had become dangerous. A new form of rabies occurred after the so-called preventive inoculations, a form which he would call "canino-experimental," and according to the predominance of action of the canine or Pasteurian virus the predominating symptoms were either those of ordinary or of laboratory rabies. It was precisely because a new, and as yet unknown, paralytic form of the disease was usually met with that the difficulty of diagnosis was so great, and that death was generally attributed to some grave affection of the nervous centres. As regarded the presence of albumen in the urine of the patient examined by M. Brouardel, it was perfectly well known, as had been shown by M. Robin, that albumen is always found in the urine of the dead subject. Since the last sitting of the Academy, notwithstanding the attempt made by the authorities to conceal the facts, M. Peter had, he said, become acquainted with three new cases of "cure" by the intensive method that had terminated fatally. The first was a man forty-seven years of age, at Dunkirk, who was bitten by a mad dog on the 18th of August. He had not been cauterised, an operation which, observed the speaker, thanks to the false security inspired by the inoculations, is at present too often neglected. On the 21st he went to the laboratory, and was submitted to the intensive treatment. On the 29th of December, 112 days after the bite, he first fell ill, and was unable either to eat or drink. In the course of the night he was seized with violent attacks of suffocation. On the 30th there were hydrophobia and convulsions, and the following day he died. The post-mortem examination showed the usual evidence of asphyxia. This, M. Peter considered, was a typical case of ordinary rabies. The second case was at Constantine. A man, forty-six years of age, was bitten on Oct. 12th. From the 20th he was treated by the intensive method. On Nov. 20th pains appeared at the seat of the bite; on the 23rd, pain was felt where the inoculations had been made, and there was sleeplessness. Breathing was impeded by the accumulation of mucus, difficult to expectorate, in the bronchi. There was aversion to fluids. The urine was albuminous. The patient died next morning. The post-mortem revealed intense congestion of the brain, including the cerebellum, and softening. Sections presented a nutmeg appearance. There was serous effusion into the ventricles. The lungs were congested. Here was a case of modified rabies of the canino-experimental kind, showing the inefficacy of the treatment, and the combined effect of the two viruses. The third death occurred at Arras, and a veterinary surgeon had said that the dog in question was not rabid. (M. Vulpian corrected this statement. Further investigation, he said, had proved that the animal really had had rabies.) The sufferer was forty-two years old, and was bitten on Nov. 12th, and underwent the intensive treatment on the 17th. On Dec. 10th he felt great pain at the seats of the inoculations, which extended from the loins up the spinal column. He was nervous and depressed, saying that he felt the same symptoms as at the time of inoculation, and felt very tired. No pain at the seat of the bite or in the corresponding limb. A doctor called in on the 13th thought he was suffering from lumbago, and a few days later changed this diagnosis for myelitis. The symptoms were accompanied later by difficulty of breathing, a feeling of weight in the front of the chest, and spitting. Speech became short and jerky, and was interrupted by involuntary respiratory movements. Convulsions occurred in the face, trunk, and upper extremities, but there were no general convulsions or hydrophobia. Paralytic symptoms set in, and the patient died on the 17th. Although there was no "hydrophobia," M. Peter considered that the case was one of rabies; and from an analysis of the symptoms that it was extremely probable that the onset of the disease was caused by rabbit-derived virus. The *séance* ended after a protest from MM. Trélat and Brouardel against M. Peter's inaccuracies, which, they said, he might have guarded against by consulting the records of the Pasteur Institute.

THE PASTEUR INSTITUTE.

The public subscription for this Institut now amounts to more than 1,500,000 fr., the seventy-fourth, seventy-fifth, and seventy-sixth lists published by the *Journal Officiel* having made up 25,946 fr. The Conseil d'Etat, which had been asked to decree the institute as one of public utility, had adjourned its decision for further inquiry.

Paris, Jan. 11th.

SANITATION AT TOULON.

(From our Special Correspondent).

THE authorities of Toulon have made some slight improvement in the sanitary condition of this most unhealthy town. They profess to have spent £16,000 during the last year in sanitary work. A very large proportion, however, of this sum has been used to defray the cost of filling up a ditch called the "Rode" and in destroying the old fortification which stood close by. The foul deposits at the bottom of this ditch are in many places two yards deep, and the ditch itself measures four yards in width and about 300 yards in length. No attempt has been made to remove the foulness accumulated here in the course of ages. It was thought sufficient to cover it all up with some three feet of earth. Even this would have cost about £20,000 had the earth been brought into the town expressly for the purpose. But by simply tumbling the fortifications into the ditch the work was accomplished for the comparatively small outlay of £5000, or 10*d.* the cubic metre of earth removed. The town of Toulon can now enlarge itself in this direction, and a better current of air is established in the streets that were formerly blocked up at one end by the city wall. But it is to be hoped that trees only will be planted on this covered ditch. They might help to purify the subsoil; houses, on the contrary, if resting on such foundations, would expose the health of their inhabitants to the gravest danger.

This work was hardly terminated before its disadvantage became painfully evident. In times of heavy rainfall the ditch served to carry some of the water away. Now the only remaining ditch in the neighbourhood empties into the port by a covered way and therefore can only carry off a limited amount of water. This brook consequently overflowed, the Rode ditch could no longer relieve the pressure, and extensive floods in the suburbs of Toulon resulted. It is even said that the damage done by these floods equals the cost of filling up the Rode.

Another ditch, called the Égoutier, is now being canalised, and this work will be finished by next April. The earthern banks will be walled up, and the bottom cemented and made concave, so that the water will be able to flow easily and leave little or no deposits. This is the only way of treating these brooks, which remain nearly dry the greater part of the year, and yet at certain times have to bear the pressure of an enormous quantity of water. Most of the towns on the Riviera, Nice and Cannes, for instance, are traversed by several of these small watercourses, and they have always been a source of nuisance. Dirt of all sorts is thrown into the river bed, and there is not water enough to carry it away. With cemented walls and a sharp invert the case is different, and the subsoil is also protected from contamination.

Though less costly, a more important improvement has been achieved with regard to the general cleanliness of the town. It is well known that many houses at Toulon have no closet accommodation whatever. The night-soil is allowed

Digitized by Google

to accumulate in deep earthenware jars, and these were generally emptied in the street gutter, whence the water, which flows plentifully, carried the sewage into the harbour. Now, however, a cart goes round every street of Toulon three times a day. This cart, or rather metallic tank on wheels, receives all the soil from the houses, and anyone now found befouling the gutter is prosecuted. I was assured by the local authorities that before the population could be taught to avail themselves of these tanks it was necessary to prosecute fifty people in a week, and still there are summonses issued daily for infraction of the law.

Again, it is worth noting that the scavenging of the town is now done by men in the employ of the municipality, and is no longer entrusted to contractors. The latter it was found were more apt to think of their profits than of the health of the town. As a result of these changes the water of the gutters falls into the port in a much purer state. As each street reaches the old port it will be noticed that the gutters fall into a sort of tank covered over with a grating or with wooden boards. Here leaves and refuse of all sorts are retained, for the water passes out into the port through iron bars, which act as a sieve. Formerly the water of the gutters was so heavily charged with refuse that from fifteen to sixteen cubic metres were withdrawn daily from these filtering tanks. Now, however, that the scavenging within the town is so much better managed, the amount of solid deposit made by the gutters as they reach the tanks close to the port only amounts to about two cubic metres per day.

In spite, however, of these slight improvements, the town of Toulon remains in an extremely unhealthy condition. Typhoid fever, always present, is more than usually prevalent at this moment. Some of the best quarters are often the most affected. Considerable fear is also entertained lest epidemics should arise from the careless treatment of the soil collected in the town and deposited a little way out in the country, where it is given to farmers for manure. This manure, consisting in part of the dejections of typhoid patients, may, if spread about on fields, contaminate neighbouring wells or watercourses. The depôt is managed in so primitive a manner that not unnatural fears are entertained as to the possible consequence.

Toulon, Jan. 2nd.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major F. A. Turton, from half-pay, to be Surgeon-Major, vice Duke Parke, retired. G. Burnett Currie (Insch, Aberdeenshire) has been appointed District Medical Examiner of Recruits for the Regular Army and Militia, vice Geo. Mackie, M.D., deceased.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned officers:—Deputy Surgeon-General Charles Planck, Deputy Surgeon-General John Brake, and Brigade Surgeon James Fairweather, M.D., all of the Bengal Medical Establishment. The Queen has also approved of the following transfer from the temporary Half-Pay List to the Retired List:—Surgeon Ernest Lawrie Robinson, Bengal Medical Establishment. The undermentioned officer has been granted a step of honorary rank on retirement:—Brigade Surgeon Charles Kelway Colston, of the Bombay Medical Establishment, to to be Deputy Surgeon-General.

ADMIRALTY.—The following appointments have been made:—Deputy Inspector-General Edward T. Mortimer, to the Hong Kong Hospital; and Deputy Inspector-General Charles H. Slaughter, to the Haslar Hospital.

ARTILLERY VOLUNTEERS.—3rd Volunteer (Lincolnshire) Brigade, Eastern Division, Royal Artillery: Edward Sharpley, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Battalion, the King's Own (Royal Lancaster Regiment): Surgeon J. Robinson is granted the honorary rank of Surgeon-Major.

BEQUESTS.—Mr. Crowther Smith of Newbridge House, who died on the 26th ult., has bequeathed £1000, free of duty, to the Wolverhampton and Staffordshire General Hospital, and the same amount, also free of duty, to the Wolverhampton Orphan Asylum.—By the will of the late Mr. George Fielder £500 is, on the deaths of certain relatives, left to each of the following hospitals: Charing-cross Hospital, Middlesex Hospital, Surrey County Hospital, and Seamen's Hospital (late *Dreadnought*), Greenwich.

NOTES ON THE CASE OF THE LATE LORD IDDESLEIGH.

DR. J. MORTIMER GRANVILLE, who was first consulted by the late Lord Iddesleigh on Feb. 23rd, 1886, has allowed us to make the following extracts from the notes taken by him whilst acting as his Lordship's medical adviser:—

Feb. 23rd.—Gouty history on father's side; agitation of right arm resembling paralysis agitans; he is able to hold his hand perfectly still for six or eight minutes. Left arm and right leg tremble very slightly; some deafness, left ear the best. Hears 28,000 vibrations per second with left. Stands well with eyes shut. Patellar-tendon reflex normal. ..... Cardiac dulness nearly normal; mitral also aortic bruits. Breathing rather rough, but free. Pulse characteristic. Two sphygmographic tracings taken decidedly mitral. Manometer: left hand, 44 lb.; right, 40 lb. Extremities cold. Urine passed at same time contains no albumen. Has been living somewhat low, and is mentally and physically depressed. Falls asleep quickly, but starts a great deal, and has once or twice jumped out of bed while half conscious. Never had epileptiform disturbances.

27th.—Sphygmographic tracing shows improvement.

March 15th.—Much better generally, and hand trembling less, assuming more the character of a choreic movement, but much less frequent. Manometer: right hand, 67 lb.; left hand, 55 lb.

May 14th.—Better considerably. Urine of twenty-four hours: sp. gr. 1020; acidity, 3·465; urea, 10 grs. per oz.; uric acid, ·3600 gr. per oz.; no albumen; no sugar.

Notes of case from this point show steady improvement until Oct. 8th, when he had slight attacks of giddiness, but never involving loss of consciousness, and apparently anæmic in character. At this time the physical signs were found to have improved, the heart's action being regular, less laboured, and the bruits less strongly marked. Sphygmograms of this date are less of the mitral type. Urine of twenty-four hours: sp. gr. 1023; acidity, 3·780; urea, 12 grs.; uric acid, ·3087 gr. per oz.; no sugar; no albumen; no excess of phosphates.

Dec. 1st.—Was sent for to see his Lordship after his return from Windsor. Believes himself to be suffering from a slight chill. Much wearied, and complains of undefined pains in abdomen. Heart sounds as before. Not sleeping well the last few nights. Has sensation of cold water running down the back.

2nd.—Much better.

8th.—Slight giddiness when going upstairs after breakfast. Did not lose consciousness or stagger, and expressed his belief that it was owing to the pressure of his cravat. Heart sounds as usual; no irregularity or intermission. Has at no time while under observation had either irregularity or intermission. No albuminuria at any time; no swelling or œdema, and no enlargement of any of the viscera.

This was the last occasion on which Dr. Granville saw his Lordship alive. On the 12th inst., at about ten minutes to three in the afternoon, he was summoned to Downing-street, and found him dead. Mr. Langston, of Broadway, Westminster, had seen him just before he died, and communicated the following statement to Dr. Granville:—"On my arrival Lord Iddesleigh was lying on a sofa, perfectly straight; extremities not drawn; no turning in of the thumbs; no distortion of the features; pupils dilated and fixed; no stertor; skin pallid, cold, and clammy; lips very slightly blue tinged; no venous engorgement; quite pulseless; no cardiac sounds discernible. He gave a gasp, and with an expiratory effort died. Hot flannel stupes were laid over region of the heart, and sulphuric ether in water was applied to the nose and mouth. It was found that he could not swallow." Mr. Hebbert, of the Westminster Hospital, arrived in a short time, after which, at Mr. Langston's suggestion, ether was injected into the left forearm, and Silvester's method of artificial respiration tried, but none of these remedies had the slightest effect. Dr. Granville, on his arrival, applied nitrite of amyl to the nose, but without result. His Lordship evidently died from the aortic valvular complication.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council held on Thursday, Jan. 13th, the Council agreed to purchase the Cobbold Collection of Entozoa, with the accompanying manuscript. This collection was made by the late Professor Spencer Cobbold. One essay has been received for the Jacksonian Prize on the Pathology &c. of the Thyroid Gland.

The following is the result in reply to the questions contained in the Circular addressed by the Council to the Fellows of the College:—

Analysis of the Answers.

Number of circulars sent out	987
Answers received	706
Difference	281
Returned through post for various reasons ...	21
Unanswered	260

From the 706 answers 6 must be deducted as giving no decision one way or the other.

Of the remaining 700 answers, it appears that in reference to Question A—In your opinion should Members of the College be allowed to Vote for Fellows as Members of the Council?

Fellows voting "No"		419
Fellows voting "Yes":		
Answers unqualified	181	
Answers qualified	95	
Total Fellows voting "Yes"		276
Majority of "Noes"		143

And that in regard to Question B—In your opinion should Members of the College be eligible for seats on the Council?

Fellows voting "No"		526
Fellows voting "Yes":		
Answers unqualified	84	
Answers qualified	88	
Total Fellows voting "Yes"		172
Majority of "Noes"		354

It was resolved that the Committee of Charters and Bye-laws be requested to send a further report as soon as possible in reference to the proposed changes in the Charter and Bye-laws.

The resignation of Professor Humphry as a Member of the Court of Examiners was accepted, and the election of a successor will take place at the next ordinary meeting of the Council.

The Council of the Metropolitan Central Branch of the British Medical Association was informed that their letter and accompanying resolutions had been laid before the Council.

A memorial signed by several medical men and men of science, referring to the disposal of the funds received by the Council under the will of Sir Erasmus Wilson, was brought forward and referred to the Committee on the question as to the disposal of such funds.

The following resolution, proposed by Sir T. Spencer Wells and seconded by Mr. J. Hutchinson, was passed by 11 to 8, subject to confirmation at the next meeting: "That—although the Council are not prepared to give effect to the recommendation contained in the first resolution carried at the meeting of the Fellows and Members held at the College on the 4th of November, 1886—the Council are prepared to act upon the second resolution, so far as to appoint a small committee to confer on the subjects of the first resolution with representatives appointed by the Association of Fellows and the Association of Members.

From the above report it appears that 706 Fellows have responded to the questions propounded by the Council in their recently-issued circular: 1. In your opinion should Members of the College be allowed to vote for Fellows as Members of the Council? 2. In your opinion should Members of the College be eligible for seats on the Council? This may, under the circumstances, be considered as a very full poll. The first question has been answered in the negative by a majority of 143. The second, also in the negative, by a majority of 354. We have from the first anticipated what the result would be; but we find cause for considerable satisfaction in the figures actually before us, especially when we consider the very misleading terms of the interrogations. That of a poll of 987 of the Fellows, only a majority of 143 were unfavourable to an extension of the voting franchise to Members of the College, whilst of the 276 Fellows who voted "Yes" 181 answers gave an "unqualified" affirmative reply, affords a remarkable indication of the growth of a liberal and enlightened spirit. This testimony is emphasised by the fact that, in reply to the second question, 172 Fellows (84 of whom returned "*unqualified*" answers) expressed an opinion that Members should be eligible to sit on the Council. Bearing in mind the restrictions as to standing which the Members themselves would impose, and which the Council in polling the Fellows left out of consideration, we cannot but regard the result of this appeal to the Fellows as eminently satisfactory, and as proof beyond all cavil of the sympathy of the Fellows in the reasonable aspirations of the Members.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentleman passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise, on Jan. 6th:—

Strickland, Percy Charles Hutchison, M.R.C.S., Ildersly-grove, West Dulwich.

THE annual ball in aid of the funds of the Scarborough Hospital and Dispensary was held on the 4th inst.

A DEATH from eating tinned salmon is reported from Dent, near Sedbergh, in the North Riding of Yorkshire.

THE distribution of prizes at the Imperial School of Medicine, Constantinople, took place in the presence of a large assembly on the 2nd ult.

HOSPITAL SATURDAY FUND.—Lord Brabazon has consented to preside at the thirteenth annual meeting of this fund, to be held at the Memorial Hall on Feb. 8th.

SUPERANNUATION GRANT.—The Poplar Board of Guardians have decided to grant Dr. S. Gray a superannuation allowance of £67 per annum for life.

ON the 8th inst., at the City and Guilds Technical Institute, Finsbury, a practical examination was held of plumbers from different parts of the country, who desired to qualify themselves for registration.

THE JAFFRAY SUBURBAN HOSPITAL.—Mr Jaffray, of Birmingham, has received from an anonymous donor the sum of £1000 towards the endowment fund of the Jaffray suburban branch of the Birmingham General Hospital.

THE HARVEIAN SOCIETY OF LONDON.—The annual general meeting of this Society will be held on Thursday, Jan. 20th, at 8 P.M., at the Stafford Rooms, Titchborne-street, Edgware-road, on which occasion an address will be delivered by the retiring president, Dr. Hughlings Jackson, F.R.S., after which a *conversazione* will be held.

SEWAGE IRRIGATION.—At a meeting of the members of the Association of Public Sanitary Inspectors at the offices of the Society on the 1st inst., Mr. James Bateman read a paper on "Sewage Irrigation Applicable to Small Areas." A short discussion followed, and the proceedings closed with a vote of thanks to Mr. Bateman.

SMALL-POX AT WALSALL.—At a meeting of the Walsall rural sanitary authority on the 7th inst., it was reported that small-pox had again broken out in the locality. An arrangement has been made with the Town Council to treat non-pauper cases in the borough epidemic hospital at the rate of £1 a week.

A MEDICAL MAGISTRATE.—At the last quarter sessions for Carlisle, Dr. Henry Barnes qualified as a justice appointed by the Lord Chancellor. Dr. Barnes has long occupied a prominent position as a physician in the north of England, and has interested himself in all medical and many public movements. His medical brethren in the north feel pleased at this recognition of his work.

Digitized by Google

ON the 6th inst. a complimentary dinner was given at Manchester to Mr. Malcolm Webb on the occasion of his resigning the post of resident medical officer at the Manchester Royal Infirmary, a position which he has occupied for upwards of two years.

ST. MARY'S HOSPITAL.—On the 12th inst. the annual Christmas entertainment was given to the convalescent patients of this hospital. The dimensions of the board-room proved scarcely adequate to accommodate the large and appreciative audience.

MANCHESTER MEDICAL SOCIETY.—The following gentlemen have been elected office-bearers for 1887:—President: Dr. James Hardie. Vice-Presidents: Drs. C. J. Cullingworth, Julius Dreschfeld, James Ross, and Mr. A. W. Stocks. Treasurer: Dr. C. E. Glascott. Secretary: Mr. F. Armitage Southam.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The Lord Chancellor will preside at a festival dinner at the Holborn Restaurant, on Wednesday, Feb. 9th, in aid of a jubilee fund for opening the whole of the wards in the new building of the National Hospital for the Paralysed and Epileptic (Albany Memorial).

WHOLESALE POISONING.—A large number of people—nearly one hundred in all—are stated to have suffered from food poisoning near Carlisle. After a dinner given at a sale of farming stock last week, all the guests who partook of peas-pudding, served with boiled beef, were seized with pain, vomiting, and other symptoms of irritant poisoning. The poison has, it is said, been traced to washing-soda used in cooking to soften the peas. All the patients are recovering.

TREATMENT OF THE METROPOLITAN SEWAGE.—The Duke of Westminster, in reply to an invitation to attend a meeting of the ratepayers of the metropolis to protest against the expenditure contemplated by the Metropolitan Board of Works for the treatment of the sewage at Barking, has expressed his opinion that the costly scheme of the Board requires a more searching examination than it has yet received. His Grace advises that memorials should be presented to the Board calling attention to the objections which have been urged against the scheme.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The following constitute the members of the Council for the year 1887:—President: Charles S. Tomes, F.R.S. Vice-Presidents: Henry Sewill, S. J. Hutchinson, J. H. Mummery, Andrew Wilson (Edinburgh), Richard Rogers (Cheltenham), and G. C. McAdam (Hereford). Treasurer: James Parkinson. Librarian: Felix Weiss. Curator: Storer Bennett. Editor of the Transactions: Frederick Canton. Hon. Secretaries: R. H. Woodhouse (Council), Willoughby Weiss (Society), and C. J. Boyd Wallis.

THE Royal Colonial Institute held a meeting at Princes' Hall, Piccadilly, on Tuesday evening, when a very interesting paper on New Guinea was read by the Rev. James Chalmers, missionary and explorer. Dr. Doyle Glanville, who was medical officer on the staff of the Royal Commission for New Guinea, and whose pictures and writings in the *Graphic* have from time to time long been familiar to the public, addressed the meeting at some length. After describing the object of the expedition and giving a general outline of its proceedings, he spoke of the London missionary labours in New Guinea in terms of the warmest praise, and concluded his remarks by alluding in feeling terms to the memory of the late Sir Peter Scratchley, who died out there.

THE VIENNA HOSPITAL.—From a statistical report of the great Vienna Hospital, which has just been published, we learn that during 1885, 26,448 patients were treated there. Of these, 13,000 were discharged cured and 4000 improved. Some were removed to other institutions, as many as 1000 being sent to lunatic asylums and more than 500 to the small-pox hospital. There were 2898 deaths. The total number of patients during the last hundred years was 1,654,729, amongst whom the mortality was 237,218, or 14·33 per cent. In 1885, which was the first year of the second century of the hospital's existence, the number of admissions was 8000 in excess of the annual average for the preceding hundred years, and 3300 in excess of that of the preceding ten years, the mortality being 0·95 less than that of the century, and 0·63 less than that of the last ten years.

CANTERBURY DISPENSARY.—On the 5th inst., the fiftieth annual meeting of subscribers to this institution was held, when the report showed that during the existence of the dispensary 76,210 persons had been attended, a proportion of nearly 90 per cent. of that number having been visited at their homes. In consideration of the fifty years' services of the medical officer, Mr. George Rigden, it was recommended by the Committee that he should be presented with £50. The report was adopted unanimously.

SANITARY REGISTRATION OF BUILDINGS BILL.—At the monthly meeting of the Council of the Sanitary Assurance Association on January 10th, a report on the draft Bill was submitted with several clauses redrawn. The Bill was further amended, and ordered to be printed for final consideration at the next meeting of the Council. The new Bill is proposed to be compulsory with regard to schools, hotels, asylums, hospitals, and lodging-houses, while Clause 6 has been made much more stringent in the matter of qualification of persons entitled to give sanitary certificates.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE USE OF COCOA.

THE total consumption of cocoa is 80,000,000 lb. per annum, supplied mainly by the West Indies and South America. France heads the list with 26,000,000 lb.; Spain comes next with 16,000,000 lb.; then follows England, 14,000,000 lb.; and the United States, 8,500,000 lb. In this last country the use of cocoa has increased more than sixfold since 1860, while that of tea and coffee within the same period has not quite doubled.

Mr. Gillett (Paris) will see from a general notice published above that we do not undertake to return MSS. not used.

Mr. Arthur Matthey.—We regret we are unable at present to answer the question.

R. S. W. has not enclosed his card.

"SUICIDE AFTER TAKING CHLORAL."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "A. P. G.," asks, in your last issue, two questions about suicide after chloral, in reply to which I submit the following.

All narcotics, including alcohol, may predispose to suicide, and I presume most practitioners could instance cases tending to prove the fact. I will record one in recent experience. On Dec. 24th, 1886, I was called to see a young Japanese gentleman, aged twenty-one, who had shot himself with a pistol, and who died two hours and a half after my arrival from the wound in the brain with compression. I had never attended him before, but he had been seen by Sir Andrew Clark, and also by another practitioner. Although the symptoms might be accounted for only by cerebral hæmorrhage, I thought it probable that there was the complication of some narcotic, and as the condition of the pupils negatived opium I inquired particularly about chloral. No satisfactory evidence could be obtained at the time, but after death when examining prescriptions that were found, I saw that chloral had been given. As no reasonable cause for suicide could be discovered save occasional depression, but, on the contrary, with position, wealth, &c., there were many things calculated to make life desirable, it seems likely that the narcotics lessened self-control, and the publication of such cases may do some good by cautioning all of us to be careful in their administration. I am, Sirs, yours faithfully,

Philbeach gardens, S.W., Jan. 8th, 1887. J. A. OWLES.

Gemma can claim one guinea for making the post-mortem examination, and one guinea for giving evidence. The number of attendances at the inquest does not affect the fee.

Mr. Lawson Tait.—The Editors are alone responsible for all that appears in the editorial columns of THE LANCET.

"COCAINE IN DENTAL SURGERY."

To the Editors of THE LANCET.

SIRS,—Having seen in your issue of Dec. 18th that M. Georges Vian has only just established cocaine as an anæsthetic in dental extraction, I think it perhaps fair to state that some six months ago I had a tooth extracted in Plymouth, cocaine being injected, with no pain. Since then I have used it frequently, and only in one case were there any toxic effects—viz., in the case of a stoker who had previously, on one or two occasions, fainted in the coal bunkers. A draught of ether and ammonia quickly brought him round. Whether syncope was due in this case to the drug, or to slight shock, the result of the operation, I could not say. Anæsthesia appears to be complete, unless there is much inflammation at the root of the tooth.

In some forms of neuralgia, depending on a local lesion, it seems to be a valuable drug. I just quote one case where its success was very marked. J. M—— complained of intense pain in the lower jaw. The face was suffused on the same side, with injected conjunctiva and swollen lids. He appeared in great pain. I examined his teeth, which were perfect, except for one which had been removed a few weeks previously on shore. As it was just possible that the pain was due to some irritation at the site of the removed tooth, I injected a grain of cocaine into the gum. Visiting him about half an hour afterwards, he said he was quite free from pain. There was no recurrence of it. The following morning the congestion of face, &c. had passed off.

I am, Sirs, yours obediently,
G. F. DEAN, Surgeon, R.N.

H.M.S. *Polyphemus*, Malta, Jan. 4th, 1887.

LIMITS OF THE CHILD-BEARING PERIOD.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if any brother practitioners can give me any definite information on the following question, either from books or personal knowledge. Is there any infallible sign that a woman is past child-bearing? Here is a case in point. A patient forty-seven years of age; last child eight years ago; irregular menstruation for some time past; nothing seen for five months, then scarcely anything, only lasting a few hours. She wishes to marry, but has the greatest objection to another young family.

I am, Sirs, yours faithfully,
December 29th, 1886. M.D.

THE PHYLLOXERA.

THE average yield of the French vintage for the four years from 1875 to 1878, inclusive, was 1,275,000,000 gallons. The last three vintages have decreased at a greater rate than 100,000,000 gallons per year, and now it is reported that in the vintage of 1886 more than one-fifth of the yield was produced from dry raisins and dregs of the first and second press. Although it is beginning to be the fashion to ascribe this decrease chiefly to mildew and other causes, the presence of the phylloxera must be regarded as one of its principal causes. After a variety of researches only one method has been found to effectually kill this insect, and that is by inundation, begun in November and continued for forty days. The vineyard on which this experiment was tried was one of the first to be attacked. In 1867 the wine produced was 925 hectolitres; in 1868, 40; in 1869, 35; in 1870, the first year of submersion, 120 hectolitres. Since that year the quantity produced has gradually increased, until it has nearly reached its normal figures, and the vines have regained their vigour. The Commission appointed in France, which publish every year such a heavy report, have chiefly studied methods for killing the insect underground, and but little practical benefit has attended their action. Had they directed their energies to a policy of extermination above ground very different results might have been attained.

A Member.—Our correspondent, having been suspended on Jan. 1st and having resigned office on the 6th, cannot claim payment of his salary beyond the 6th for deprivation of office which he did not feel disposed to resist. The only case to which the rule applies is where the guardians have suspended the officer and it is referred to the Department for their decision, when it is competent for the Department to allow payment of salary up to the time of removal, of suspension, or confirmation of the same.

Dr. Fraser.—The case seems hard, and the decision is probably wrong, but we fear our correspondent is without redress.

PERSISTENT DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—I should feel greatly obliged if some of your readers who have treated similar cases successfully would give me a few suggestions to help me out of my trouble.

I am suffering from diarrhœa, with griping and flatus, the result, I believe, of superfluous bile from an enlarged and unusually active liver. I cannot say that I have any other symptom specially worthy of note. In 1873 I went to the West Indies, and remained there till January, 1877, faring somewhat hardly as regards food, and in consequence drinking brandy pretty freely, though never to intoxication. During this period I had several attacks of the ordinary intermittent fever of the island, but none of any noteworthy severity. On my return to England in January, 1877, I was suffering from atonic dyspepsia and congestion of the liver. Shortly after my return I got a severe chill, and this brought on a violent attack of ague, which recurred at intervals with gradually decreasing force for upwards of a year. I remained in England until June, 1881, when I returned to the West Indies, apparently in perfect health, the congestion of the liver having disappeared in deference to podophyllin when indicated. I remained in the West Indies until June of last year, living very temperately but working very hard, both mentally and bodily, having many irons in the fire requiring my personal supervision. In November, 1885, I had a severe attack of bilious remittent fever, and in April last an equally severe attack of obstruction of the bowels, followed by a less severe attack of obstruction on my passage home in June. Since that time the diarrhœa has been almost constant. I am unable to take opium in any of its ordinary forms; but from time to time I have had relief from small doses of akolethe, of which I can speak in the highest terms. Still, I do not care to be dependent on any opiate, and I should like to get something more than temporary relief.

I am, Sirs, your obedient servant,
January, 1887. L.R.C.P.

To the Editors of THE LANCET.

SIRS,—I have just seen a letter in your issue of the 18th ult., signed "A. H.," asking advice as to the treatment of an obstinate case of diarrhœa. I would advise your correspondent to examine the rectum, as I have known several instances in which obstinate diarrhœa was caused by ulcers, fissures, or even very slight abrasions of the mucous membrance of this gut, and which at once got well when the rectal ailment was cured.

I am, Sirs, yours truly,
January 10th, 1887. J. I.

BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—The annual general meeting of subscribers to this fund, which was held yesterday, commissioned me to offer you an expression of thanks for the services you have rendered to the fund during the past year, by so freely and generously opening the columns of your valuable journal to the communications addressed to you with regard to the fund, and to express a hope that so useful an indulgence may be continued.

I am, Sirs, yours truly,
Upper Berkeley-st., W., Jan 11th, 1887. EDWARD HAST, Hon. Sec.

Digitized by Google

RIDDELL FUND.

THE following additional subscriptions have been received:—Amount already acknowledged, £50 3s. 6d.; D. P. (per Dr. Dolan), £1 1s.; Dr. Whitwell, £1 1s.; Dr. Fegan, £1 1s.; M.D., 10s.; H. T., 3s. 6d. The list will close on Jan. 19th.

Mr. Easterbrook.—We are not in a position to give a reply. Perhaps a letter to the Rev. Dr. Forrest, of St. Jude's, South Kensington, would elicit the information desired.

J. R. P.—Allen's Commercial Organic Analysis, published by J. and A. Churchill, would probably answer the purpose.

PARISH PRACTICE AND ITS REMUNERATION.

To the Editors of THE LANCET.

SIRS,—I would direct the attention of the profession to the advertisement of the Lampeter Union in your issue of Jan. 8th. No doubt there will be a great rush of the unemployed to secure such a lucrative and easily-worked appointment. For the privilege of physicking the paupers of the parish of Llanfihangelrhosycorn and the adjoining parishes the guardians offer, forsooth, a salary of no less a sum than £30 per annum, and at the same time gently announce the acreage of the district. The area of the combined parishes is stated to be 34,700 acres. The advertisement calls to mind some lines of Albert Smith:—

> "The parish is small—ten miles by sixteen,
> With some commons and gravel-pits scattered between;
> And respecting the cases, to state 'tis p'r'aps right,
> That they always occur at the dead of the night."

I am, Sirs, yours very truly,

Pangbourne, Reading, Jan. 10th, 1887. W. T. FREEMAN.

TOOTH POWDERS.

IN reply to several correspondents, we may say that the amount of precipitated chalk implied in the formula which we gave in our issue of the 1st inst. was 2 oz. (not 1 oz. as was erroneously printed in our last, in answer to Messrs. Habgood and Cooper).

M. J. Knight.—Reynolds' System of Medicine, Pepper's System, Hirsch's Practical Pathology, Dr. D. Friere's Monograph.

EMASCULATION OF FOWLS.

To the Editors of THE LANCET.

SIRS,—I would be very much obliged if any of your readers could give me some information about the emasculation of fowls, and if there is any book which gives directions as to how the operation is performed.

I am, Sirs, yours faithfully,

January, 1887. B. L. T.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Lawson Tait, Birmingham; Sir W. MacCormac, London; Dr. George Johnson, London; Dr. Bristowe; Mr. Jessop, Leeds; Dr. Goodhart, London; Dr. C. W. Dulles, Philadelphia; Mr. F. Easterbrook; Messrs. Arnold and Sons, London; Mr. Rockliffe, Hull; Mr. Hussey, Oxford; Mr. J. Bell, Suez; Mr. Benthall, Southsea; Dr. Campbell, Carlisle; Mr. S. Snell, Sheffield; Dr. F. A. Smith, Cheltenham; Messrs. Burgoyne and Co., London; Rev. W. Homfray, Retford; Messrs. Hopkinson and Co., London; Mrs. Learmonth, Kentish-town; Messrs. Address

DELIVERED AT THE

PATHOLOGICAL SOCIETY OF LONDON

On Tuesday, January 18th,

BY SIR JAMES PAGET, BART., F.R.S.,

PRESIDENT OF THE SOCIETY.

GENTLEMEN,—I thank you heartily for the honour you have conferred on me by electing me to be your president. It is a great compliment that I should still be thought fit to be president of a Society of which the most active members are much younger scientific men, some of whom are studying pathology in subjects and with methods almost unknown to me. If I can be at all fit for the office, it may be because, in my very imperfect knowledge of many of the numerous methods in which pathology is now studied, I can look with full respect upon them all; and, indeed, there are few things in relation to our science of which I am more sure than of this, that every possible method of studying it should be by all possible means promoted. And while I am your president this shall be my object, so far as I may have power.

I hope I shall not prove myself unwise if I do not take for the subject of my address that kind of knowledge in which alone I might claim superiority over my hearers—namely, the personal memories of the far distant past. It would be very pleasant to me to tell some of them, and might be amusing and flattering to those who can compare the best modern knowledge with that which it has displaced. But it may be more useful to think and speak of what may next be done, and how to do it. For every increase of knowledge brings before us a larger and clearer view of the immeasurable quantity which is still to be gained. The more we know, the more can we see, if we will, how much more there is that we do not know.

I wish I could indicate all or many of the ways in which new knowledge is to be gained; but I cannot. It is characteristic of modern pathology that, as it certainly surpasses all other sciences in the variety and complexity of its problems, so it offers work sufficient for the employment of nearly every variety and opportunity of the scientific mind. Pathology, as distinguished from practical medicine, used to be regarded as scarcely more than morbid anatomy; but now there is in it work not only for the anatomist and physiologist, but for the clinical observer, the experimentalist, the minutest microscopist, the statistician, the chemist, the naturalist, the historian, the psychologist, and yet more. I cannot pretend to be all these; and I will not pretend to decide who has done the best work or is most likely to do it in the future. Only, it is certain that complete pathology must be constructed from the works of all these; they are all mutually dependent, mutually corrective; none can alone suffice, and none can safely be neglected.

But, of all the methods of study, there are only two with which I have been much occupied—those, namely, of pathological anatomy and of clinical pathology in active practice. I can therefore speak of the future employment of only these two. But I will hope they may suffice, especially as the greater part of the members of the Society are engaged in them, and because we may justly believe that practice and pathological anatomy, if they be studied with the scientific mind and methods, will still contribute largely to the progress of the whole science of pathology.

I say practice studied with the scientific mind, because practice is often spoken of as if it were altogether distinct from science and inconsistent with it. We hear science and practice spoken of as in opposition, and sometimes as if they were mutually distrustful. I will not deny that strange contrasts of the practical and the scientific may be found among us; but these contrasts are constantly becoming more rare; and it is an excellent influence of this Society that it tends to cultivate the scientific mind and to maintain it in the practical life. For what practice may be depends, in all respects, much more on the person engaged in it than on its own subject-matter. It may be for one a noble profession, for another a vile trade; and in equal contrast it may be a mere useful art practised by one who has neither love nor knowledge of any science, or to the man of scientific mind it may be a thoroughly scientific study as well as an applied science. I could name many living in active practice of whose work a great part is as definitely scientinc as is that done in any other section of biology. And so are the works of many who are gone. For example, I know no reasonable definition of science which would exclude the researches by which Bright attained the knowledge of the disease which bears his name; or which, in a just history of pathology, would separate, as if they were of different merits, the clinical and the experimental researches from which we have our knowledge of the diseases of arteries and veins. Surely, it would be hard to name a discovery in biology which more deserves the name of scientific than does Jenner's discovery of vaccination; and yet it was made in the plainest practical manner while he was a country practitioner. But, observe, Jenner was a thorough naturalist, trained by John Hunter; and I suspect it will be found that all the best advances in clinical pathology, the best not only in their utility but in their fitness for adjustment among the largest principles of our science, have been made by practitioners who were either by nature or by cultivation men of scientific mind. And it is as sure as anything of the kind can be that similar studies by men of similar mind will still attain as good results.

Practice is full of opportunities for science. Let me suggest only one group of them. Reflection on any day's work in practice may convince us that we have been using a good deal of knowledge or belief which we cannot explain by its relation with other knowledge, whether in pathology or any other branch of science. We may have given what are called specific medicines, or have advised some one in the belief that he was predisposed to some disease, or may have talked of functional diseases. Yet I doubt whether in any of these things there are more than unexplained facts; and if there are not, then we may be sure that the facts are very hopeful beginnings for scientific study by those engaged in practice. I may illustrate this by the example of the use of some of the specific medicines, such as that of quinine in malarial diseases, of mercury and of iodide of potassium in syphilis, of arsenic in many cases of psoriasis, or of bromide of potassium in some cases of epilepsy. Here are sure facts, practical and useful, as sure as anything in therapeutics. I would not call them scientific, for, so far as I know, they are isolated facts, and separate from what may be called general laws in biology. They are, indeed, the chief of those facts which, in some minds, bring our clinical pathology into discredit; for, being only useful and not scientific, they are cited as examples of unscientific practice. They are called empirical, and the empiric is deemed equivalent with the quack. Let me say, as in parenthesis, that I think we have here an example of the common fate of words in our language—that if a word acquires a discreditable meaning, its better meaning is gradually lost, and only the worse remains with it. For the empiric and the experimentalist are, I think, synonymous; and yet in pathology the one, having a degraded name, is now deemed a hopeless hindrance to progress, and the other is its hero.

But, however this may be, among these empirical facts modern scientific work in practice may win great riches for pathology. For the medicines I have named are not only remedies, but diagnostic tests; they prove differences among diseased conditions that in other things appear alike. The epilepsy which is averted by the habitual use of bromide of potassium cannot depend on the very same conditions as that which is not so averted; the ulcer which heals under the influence of mercury cannot be of the same kind as that which looks like it but does not so heal. Thus, as we all know, these medicines are tests; and we may guess that each of them detects the presence of some material belonging only to the disease which it cures. Here, then, is work for the scientific practitioner; he may find the material and more, if he will observe the facts in practice much more minutely, and record and collect them, and bring to bear on them as much light as possible from other sections of pathological science. They will yield more knowledge, and his practice will be promoted to a better title than "empirical."

Let me again refer to some facts which I have already mentioned, and which are now accepted in the largest principles of pathology. I remember that during my apprenticeship, more than fifty years ago, in a post-mortem exami-

Digitized by Google

nation of one who had died with dropsy, a young Guy's man cut across one of the kidneys, and said "Dr. Bright, of Guy's, says there is a form of dropsy which is always associated with disease of the kidneys." This was accepted by the practitioners standing by as a singular fact, and nothing more. I should find it difficult to tell now into what, with fifty years of scientific culture, that singular fact has grown. Or, again, could any fact stand more alone than did that of the use of vaccination as first observed by Jenner? And now it may be honoured as the first knowledge attained in all that wide range of pathology in which Pasteur's great work has been done, and to which Power and Klein have lately annexed their admirable discovery of the true source of the milk scarlatina.

There are many more of this group of the facts of which we have better knowledge in practice than we have in morbid anatomy or any other section of pathology. We are sure, for instance, that there are certain conditions which are justly called predispositions to disease; but in what many of these consist we are, I suppose, quite ignorant. There are diseases or disorders which we must be content to call functional, though I suppose none of us would hold that there can be any change in the working of a part without a change in its structure or composition. We know that certain disorders, such as typhoid and scarlet fever, are apt to be followed by certain other disorders, which we call their sequels; but we have not yet shown the changes of which the sequence is a necessary consequence. We know that different morbid conditions may be combined, as in diseases which we may call hybrid or mongrel; we can recognise many of these combinations during life; they are things to be "attended to," as we say, in treating cases; but of the allied varieties of morbid changes of structure or composition, and of the lessons they would teach, we know, I think, at present very little.

How may these defects be remedied? Surely, the best way will be by study and minute scientific work in practice. I say emphatically minute work, for I think it can be proved by the example of other sciences that the more minute the inquiries and the facts obtained by them, the more sure and complete will the fusion of pathology become with the whole body of biological science, and the more will it thence gain.

Now, these more minute investigations may be made not only in the records of clinical observation, which may be far more minute than they are now, but, I venture to think, even in microscopic examinations, especially if these be made whenever it is possible on the living as well as on the dead morbid structures. I would not, in any degree, depreciate the value of the knowledge gained by examining the well-defined structures which are shown in microscopic specimens prepared with hardening and staining and other fixing processes. They ensure a more exact diagnosis, and they may be studied deliberately and with comparison; but while they have all the value, they have also some of the defects, of botanical specimens dried and flattened in an herbarium. These are essential to accuracy in descriptive botany, and to the diagnosis of species and varieties, but the vegetable physiologist must study living things. The herbarium tells little of the true plant-life, and of many processes in which that life is expressed, such as the minute intra-cellular movements and others of the like kind. Things of this kind, and important differences among them, may be found if the method of examining still living tissues can be improved, and if it be the rule to examine each morbid growth or product both directly after its removal from the living body while it may be deemed still alive, and after it has been prepared for repeated examining by staining or other like processes. I venture to expect that by methods such as these, and with improving microscopic power, the sight may often reach far beyond the boundary of what has yet been seen, and will detect differences of structure or of movement in what we are at present obliged to call structureless. And, even beyond this, I would hope that the microscope, with microscopic chemical tests, will detect differences which must be referred to differences of composition rather than of anything that can be called structure, and yet not less decisive of distinctive properties.

But I will not go on thus hoping, and perhaps only guessing. Let me only add one warning suggested by that word "structureless." It suggests the recollection that we are all apt at times to submit to the fascination of promises of finality; to find comfort in believing that we have really reached a boundary; that something is really structureless; or that there is a protoplasm which is the same always and everywhere, at least in the same species; or that in apparently similar substances there may be differences of potentiality; as if in things material there could be differences of power or property without differences of structure or of composition. We should get rid of these idle-making fallacies. The protoplasm in every structure, or of every embryo, must be as essentially different from that of every other as is the structure or the creature which in due time it may become; and these differences will be discovered by our successors if we—I mean you—do not discover them. And for one caution more. Let us never be content with present utility. Glad of it we may well be, and even proud, for science cannot be degraded by being useful in good things, and I suppose that of all utilities none can minister more happiness to those who most need it than ours may; but we must not be content with it as it is; it will be increased by every increase of our real knowledge.

Let me, before I end, again express my regret that I have been obliged to limit myself thus narrowly in speaking of pathology. Let me repeat that it is only because I have too little knowledge of other methods of study to speak of them definitely or even safely. But I earnestly hope that in our meetings we shall have contributions from them all, for all are essential to the progress of our science, and it will be a singular pleasure to me if, in my office as president, I can promote them. To do so will make my office very happy and very useful to me in helping me to avert that sad defect of old age, the indifference or dislike to the changes which come of the increase of knowledge. One sees that, as men grow old and wish for rest, they are prone to ask, Where are we to stop? I do not know more than this: that we must not stop where we are; we must go on and on, and we may be sure that they who work to find the truth will not work in vain—sure that with true work true good will come. So I will hope that it may be here during my presidency.

Harveian Lectures
ON
CANCER OF THE UTERUS.

By J. WILLIAMS, M.D. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE II.
CANCER OF THE CERVIX.

GENTLEMEN,—We now pass on to the consideration of cancer of the cervix proper, but before entering upon this part of our subject we must take a rapid glance at a condition which has received a great deal of attention from time to time, and for which many kinds of treatment have been practised, but whose nature remained quite unknown until revealed recently by the investigations of Ruge and Veit. I mean so-called ulceration, abrasion, or erosion of the os uteri. This is situated on the lips of the uterus, on one or on both. It is of a red colour, and in some cases forms a narrow ring around the os; in others it is limited to one lip; in others, again, it covers an area as large as a florin, and involves apparently the entire surface of the lips. The surface is soft and often covered by papillæ, which bleed readily. The condition is neither an ulcer, an abrasion, nor an erosion. There is no loss of tissue, and the surface is covered by epithelium, but it is epithelium of the columnar kind. The columnar epithelium has encroached upon the territory of the squamous and displaced it.

An erosion may present an appearance very like that of cancer, and, on the other hand, cancer may appear very like an erosion. In such cases it is not possible to recognise the real character of the morbid process at once except by the microscope. Clinical observation fails here unless ample time be given, and sometimes this is done and the consequences are disastrous in those cases which prove to be malignant, for when time has solved the difficulty it is too late to have recourse to any curative treatment with any chance of success.

What is an erosion? and in what does it differ from cancer

Digitized by Google

and adenoma? I cannot describe it better than by saying that it is like an extension of the mucous membrane of the cervical canal through the external orifice on to the lips, which are in health covered by stratified epithelium. In some cases an appearance like that of an erosion is caused by a hypertrophy of the mucous membrane of the cervical canal, bulging downwards through a more or less patulous os with soft lips, as is sometimes seen in pregnancy. In cases of this kind the transitional epithelium is retained, and it can be easily seen in the space between the squamous and columnar epitheliums. A true erosion, however, consists of a structure like that of the mucous membrane of the cervix placed on a surface which in health is covered by squamous epithelium. It may be, and often is, associated with a hypertrophy of the mucous membrane of the lower part of the canal. It contains glands lined by columnar epithelium, and its surface is covered by epithelium of the same character. An erosion differs from cancer in that the epithelium on its surface and lining its glands consists of a single layer and assumes no aberrant forms, and from adenoma of the cervix in that the glands are comparatively superficial, as well as in some other respects which I shall refer to later.

Ruge and Veit state that the glands of an erosion arise from a change in the deeper layer of the stratified epithelium which dips into the substance beneath and forms glandular processes. I have not been able to trace this mode of gland formation in erosions, and the process appears to be somewhat improbable. There are two ways in which erosions may arise, and one in which they are certainly produced. On examining a cervix upon which an erosion is seated, you will see little red points on the surface of the squamous epithelium near the edge of the erosion, and sometimes small islets of pale squamous epithelium in the midst of a red erosion. These points and these islets clearly indicate the manner in which the erosion has been formed. The little red points are small glandular processes from the cervical glands growing into the superficial layers of the cervix, and making their way to the surface. In speaking of cancer of the vaginal portion, I said that the squamous epithelium falls off at the points where papillæ grow through the surface and protrude. They do not carry a layer of the horny epithelium with them as a covering. The same thing happens when a glandular process in the cervix abuts against the epithelium; the epithelium becomes thinner and thinner, and ultimately disappears.

In cases of erosion the glands of the lower part of the cervix are greatly enlarged and multiplied. They enter deeper into the cervical wall, and their interior is frequently covered by papillary processes. Although these glandular processes penetrate into the wall of the cervix, their line of penetration appears to be superficial, for they run downwards and outwards, and invade the layer of tissue immediately beneath the squamous epithelium covering the portio. They burrow, as it were, in the tissue beneath the epithelium, and send processes through it to the surface. This manner of growing gives to the border of the erosion an irregular outline, and, moreover, occasions the presence of the red points on the squamous surface, where the epithelium is thinned or wanting, as well as of the islets of squamous epithelium in the midst of erosions where the original squamous epithelium has missed transfixion by the glandular growth. When the squamous epithelium has fallen off, its place is taken by columnar epithelium. The glands are lined by columnar epithelium, which is usually like the epithelium of the cervical follicles; its cells are often oblong, but frequently they are elongated and apparently pointed, with their points a little separated, and the prominence of a papilla on the inner surface of a gland then looks like the end of a brush with radiating hairs.

Another way in which an erosion may be produced is by direct extension downwards of the epithelium of the cervical canal—a direct encroachment upon the territory of the squamous by the columnar epithelium, followed by the growth of villi and the formation of glands. This mode of production, however, I have not observed, but I think it by no means an improbable method.

The wealth of glands in an erosion is usually great; they branch and divide and form clusters of follicles having one tubular outlet. Some appear to remain simple. Their interior is often, however, divided by papillary processes in such a manner that their lumen forms a very complex labyrinth. While the glands are thus rapidly growing the stroma around is not inactive, and takes not an inconsiderable part in the formation of the erosion, for it is infiltrated with nuclei and small cells, and from it are formed the basis of the numerous papillæ which contribute to the complexity of the glandular structures. But besides the common glandular erosion there is occasionally found around the os externum and in the lower part of the cervical canal a villous growth. It is believed that such growths have a great tendency to take on a malignant character, though they are benign at the outset. Scientific evidence establishing this view I am not acquainted with. I have seen three cases of villous growths at the os externum, and one in which the whole of the cervical canal was affected. The two in which the parts around the os only were affected presented no malignant structures; the other in which the whole canal was diseased showed early cancer in the glands. These cases supply no evidence for or against the view in question, and I have therefore formed no opinion about it.

CASE 9.—The first case was a married woman twenty-eight years of age, who complained of having had bearing-down pains for eighteen months; they came on every fortnight; for two weeks before admission she had had continuous aching pain in the bottom of the stomach. The catamenia were regular, and the patient had no other discharge. She was married at nineteen, had had three children, with good gettings up, and had nursed all her children. She had had a tumour as large as a nut removed from the forehead and another from a toe when a child. The area of the lips of the cervix was as large as a florin. The enlargement was limited to the lips. It was of a red colour and granular to the touch. This looked like hypertrophy of the mucous membrane of the lower part of the cervical canal. Posteriorly the growth was sharply defined, but anteriorly it gradually shaded off into the healthy surface covered with squamous epithelium. The uterus was of normal size and freely movable. The cervix was amputated: an inch was removed. The part removed was laid open by section of the anterior lip in the middle line. The disease was limited to the surface around the os and about a third of an inch up the canal. It was of a villous character, and grew from the whole circumference of the canal except the left side, which had been lacerated. Near the edge of the growth there were islets of mucous membrane covered by squamous epithelium; through some of these the growing papillæ were seen beneath.

CASE 10.—This patient was sent up to University College Hospital by Mr. Pratt, of Leighton Buzzard. She was twenty-three years of age, and not married. Her illness began three years before, when severe pain began to accompany menstruation, seated chiefly in the hypogastrium, but extending into the iliac regions also. It was of a sharp, shooting, burning character, lasting for five or six hours, after which shooting pains continued for two or three days after the period had ceased. Menstruation first began in her sixteenth year; it was irregular for twelve months, moderate in quantity, and painless. She was in service until three years ago, but owing to her present illness she had to give up work. There was a great deal of viscid mucus in the vagina. The lips of the cervix looked like a red vascular growth, not unlike a malignant growth. The os was a long transverse slit in its centre. It bled on being touched. The cervix was amputated half an inch above the disease. After removal the disease was seen to be formed by an exuberant growth of mucous folds, which grew from all the circumference of the os, and extended up the canal for a third of an inch. Its limit towards the vaginal portion was abrupt, and the folds in this situation were smaller than at the os externum.

In both these cases microscopic examination revealed nothing but rapidly growing papillæ and glands. There was no cancerous change in any part.

Glandular growths limited to superficial tissues lead us naturally to glandular growths which are not thus limited, and which involve deep structures, affect the whole thickness of the cervix, and invade the connective tissue beyond. These are adenomata, and possess malignant properties. They appear to be rare; for with the exception of Schroeder, Ruge, and Veit, who have described a case, I know of no other author who has referred to them. I have seen two cases of this affection, and both were taken for cancer. Indeed, I know of no means by which they can be diagnosed clinically, though the diagnosis can readily be made with the help of the microscope.

Digitized by Google

CASE 11.—The first case I saw was a married woman, forty-nine years of age, who had had eight children and five miscarriages. Menstruation had ceased two years before she came to the hospital, and she had "seen nothing" since until May, 1885—four months before admission. Since May she had lost a great deal of blood and suffered much pain. She had had a white discharge from the beginning of the year, and lately this had become offensive. When admitted she complained of pain in the bottom of the stomach, back, and thighs, of a dull aching character; it was sometimes severe. The duration of the attack varied; the pain always ceased on lying down. She had lost flesh lately. Micturition was very frequent and painful. She began to menstruate in her sixteenth year; she was regular every twenty-eight days; the flow lasted a week, and was moderate in quantity. She had suffered from leucorrhœa all her life. She was married at twenty-two. All her labours were good. There was no history of tumour or cancer in the family.

There was much purulent discharge in the vagina, and the mucous membrane was red and injected. The upper part of the vagina was occupied by a large mass, which was the diseased cervix of the uterus. The disease involved most of the posterior lip and a part of the anterior, and had invaded the insertion of the vagina both anteriorly and posteriorly. The vaginal surface of the cervix was intact—that is, the stratified epithelium was still retained, but it was generally thinner than it is in the absence of disease. The degree of thinning varied; in some places it had almost disappeared, while in others it was nearly of normal thickness. Immediately subjacent to it was a layer of tissue of irregular thickness, which appeared to be the tissue of the cervix infiltrated with small cells. This layer was everywhere thin, though not everywhere of uniform thinness. The rest of the tissue was formed of innumerable glands, with a scanty framework between them of fibrous tissue full of round cells. In fact, the cervix had been changed into a glandular mass. These glands were of every shape and form. Their cavities were often of great size; some were like great collapsed sacs lined with columnar epithelium. They differed in a marked degree from the glands in an erosion by the absence of papillæ on their inner surface. They were lined by a single layer of columnar epithelium, the cells of which were regularly oblong. The cells generally presented no cancerous change. This appears structurally to be a pure adenoma, but it possessed distinct malignant properties. The whole thickness of the cervix and the connective tissue beyond it had been invaded.

CASE 12.—The second patient was forty-four years of age, married, and was admitted into University College Hospital in August, 1886. She had been regular until eighteen months before, when she had a flooding; since that time she has had a profuse flooding every ten or fourteen days. She has suffered from a thick, yellow discharge for the same period, but it has not been offensive. She has had no pain. Micturition has been normal, as well as defecation, but the bowels have been confined. She has lost a stone in weight during the last two years, and has frequent nausea. Menstruation commenced at thirteen; it was regular every month, lasting two or three days; the flow was not much, and was painless. She had continuous leucorrhœa. She was married at twenty-three, has had three children, the last twenty years ago; she has had one miscarriage since. Her labours were good, but she regained her strength slowly. She nursed her children for about eight months. Two brothers and one sister died of consumption, but there was no history of cancer in her family. Pulse 99; temperature 99·2°.

She was fairly nourished. There was a thin watery discharge from the vagina. The cervix was represented by a mass which felt rough, like the head of a cauliflower. It was half as big as a man's fist, and grew from the whole of the cervix. It nowhere invaded the vagina, but on the sides posteriorly it extended as far as the vaginal insertion. The body of the uterus was anteflexed and slightly enlarged. There was no induration to be felt around the uterus on examination by the vagina and by the rectum. The obturator glands could not be felt, and the glands in the groins were not enlarged. The mass was scraped away, and it was found that the whole of the cervix up to the inner orifice was diseased. The microscopic appearances presented by the growth were similar to those in the previous case; but the stratified epithelium was everywhere thinner, though in part retained.

We now proceed to the study of true cancer of the cervix, distinguishing it from malignant adenoma by characters which I shall describe. It may begin in almost any part of the cervix, and we will begin with an account of it as it is met with in the lower part of this structure.

CASE 13.—For notes of the first case I am indebted to Dr. George Bird, with whom I saw the patient. Previously to her marriage, at twenty-two, she had enjoyed good health. The cervix was divided bilaterally in 1876. She went to India. In 1877 menstruation recurred every three weeks. In 1885 menstruation was excessive, lasting seven days. The cervix was ulcerated, with stringy discharge issuing from the os. She had no bearing down, but much aching pain in the vagina. The os bled on being touched. She first noticed excessive menstruation in 1883. She had a discharge which was slightly tinged with blood escaping during micturition. A sojourn at Malvern improved her condition, and in February, 1886, it was noted that the periods lasted five days, the intermenstrual interval being twenty-one days. She was losing flesh. When I saw her there was an erosion on the cervix, and the canal was filled with a soft dark-red growth, which bled freely on examination with the finger.

The cervix was amputated at the inner orifice. On cutting open the part removed, it was seen to be covered with villi almost three-fourths of an inch long and of a dark-red colour. They were in the main simple, and not branched—in fact, not unlike the simple tentacles of an actinia. The squamous epithelium of the portio was intact, but there was an erosion at the os with numerous large glands. Just within the external orifice were some superficial glands undergoing cancerous degeneration. The upper and more superficial part of the gland was lined by healthy columnar epithelium. In the deeper part it was many-layered, and filled the lumen so that the fundus of the gland appeared like the end of a club. This little mass was nodular, and short processes of fibrous tissue projected into its interior like imperfect septa, the alveoli formed by them being filled by cancer cells. It seemed as if a gland, in the fundus of which were many papillæ, had become cancerous. The transition from the columnar epithelium into cancer was well seen. The cells became many-layered and, losing their columnar form, became many-shaped. In many places there were vacuoles containing several small cells or nuclei, generally closely aggregated together; in others more loosely. The cancer in this instance began in the superficial glands or in the deep recesses between the villi, and not on the villi themselves. The cervix was removed because the villous growth was suspected to be malignant. The villi were not cancerous, however, although cancer was present at their bases, and it was present at such an early stage that it would have been impossible to discover it except by the aid of the microscope, for it gave rise to no physical signs which would lead to a suspicion of its presence. It is, I think, certain that in this case the growth of villi preceded the growth of the cancer; but this does not prove the tendency of villous growths of the cervix to become carcinomatous, for the cancer attacked structures which are present in every healthy cervix—namely, the glands, not the villi.

CASE 14.—In the next case cancer had attacked the lower two-thirds of the cervical wall and formed a kind of nodule in it. The patient was admitted into University College Hospital on Jan. 23rd, 1884. She was forty-two years of age and married. She had always been a strong healthy woman previously to her present illness. About Christmas, 1882, she noticed that she was growing stouter and fancied that she was pregnant; at the same time there was milk in her breasts. At the beginning of her illness she had a discharge of blood from the vagina during micturition; this discharge would last for a week or a fortnight, and then cease for a time; it only appeared during micturition. For a long time—she does not remember how long—she has been subject to bleeding after coitus, but in August, 1883, connexion was followed by a large flooding; since that time the hæmorrhage has been almost continuous and liable to be greatly aggravated by exertion of any kind. Previously to August the discharge was almost pure blood, but during the last four or five months a yellow discharge appears whenever the bleeding ceases. The discharge has been offensive throughout. She has had a dull aching across the loins, but no pain in the stomach. There has been no difficulty in micturition or defecation. She has lost flesh lately. Menstruation began at fifteen, and has always been regular, and never painful. It returned at intervals varying between three and four weeks, and lasted three days each time until four years ago; but from that time on, the flow lasted for not more than a day. The loss was not excessive.

Digitized by Google

The patient was married at thirty-four, and has had one child; her labour was easy and natural; she has had no miscarriages. Her father died of cancer of the stomach, and her mother (at fifty) of "effusion on the brain"; brothers and sisters healthy.

The whole uterus was extirpated. The following description is by Mr. Victor Horsley, M.S.:—The parts removed consist of the uterus and parts of the vaginal wall. The body of the uterus was healthy. The cervical wall is occupied for its lower two thirds by a whitish mass of new growth which apparently ceases above by a well-defined margin. The rest of the cervical wall is pale almost as far as the internal os. The new growth has infiltrated the lips of the external os, so as to form a large bulbous swelling around that orifice, especially anteriorly, where the growth is about one-fourth of an inch in thickness. At the upper part, where this growth appears to finish, the muscular wall is pressed upon so as to form a sort of capsule. The under surface of the lips is exteriorly ulcerated, and this condition extends upwards along the right side of the cervix as far as the middle. On the front wall are still present remains of the arbor vitæ. The surface of the vagina posteriorly is encroached upon for a distance of half an inch. The margins of the ulcer are thin, but raised.

This was a typical case of cancer growing from the cervical glands. The patient died, and the lymphatic glands along the iliac vessels and one gland at the bifurcation of the aorta were considerably enlarged and infiltrated by creamy white new growths.

(To be concluded.)

ABSTRACT OF THE

Lettsomian Lectures

ON SOME OF THE

MENTAL AFFECTIONS OF CHILDHOOD AND YOUTH.

Delivered before the Medical Society of London, January, 1887,

BY J. LANGDON DOWN, M.D. LOND., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE II.

Causes of Idiocy: Causation of Accidental Cases.—The history of the "accidental" cases usually elucidates the cause. Necessary instrumental interference at birth was the cause of a few cases only. During the later years of Dr. Ramsbotham's life the lecturer took great pains to investigate the subject, and he found among the great number of feeble-minded children about whom he could get thoroughly reliable accounts that in only 3 per cent., including members of the three great classes, had the forceps or any other instruments been employed. It is probable that in 9 per cent. of purely "accidental" cases instrumental interference might have been the principal factor. Prolonged labour was far more important in the production of accidental cases. In the paper read before the Obstetrical Society of London, Dr. Down found that in as large a proportion as 20 per cent. of all idiots there was an undoubted history of suspended animation at birth requiring active efforts to bring about resuscitation. He believed that many surgeons could testify to the frequency of association of contractures and other lesions with suspended animation at birth. First labours being longer than later ones, first-born children more often owe their idiocy to prolonged parturition. It was "not proven" that ergot of rye given during labour was a cause of accidental idiocy. Insolation in infancy is certainly a cause. Opium was regarded as an infrequent cause. "Much more tangible as a cause is morbid sexual erethism, too often induced by nurses, who procure the quietness of their charge by means which, even if mental health is not sacrificed, lead eventually to grave moral delinquencies." Traumatic injury to the cranium from falls is a cause, though not a frequent one, of accidental idiocy. Meningitis very frequently leads to it. So also do epileptiform convulsions, whether eclamptic or not. Hydrocephalus and paralysis from cerebral hæmorrhage are occasional causes.

Causation of Developmental Variety.—Deterioration of mother's health, especially during the sixth or seventh month of pregnancy, is a potent cause. Causes of congenital idiocy operating during the later part of pregnancy produce the "developmental" variety. Vomiting, uterine hæmorrhage, great emotional disturbance, and grave febrile disease, were the most important causes of deterioration of the maternal health.

Causation of Congenital Variety.—In a large number of cases Dr. Down is convinced that several factors have been in operation. Heredity was an important factor. In the investigation of 2000 cases, 36 per cent. of the fathers and 38 per cent. of the mothers showed no history of neurotic disease. But only in 16 per cent. did Dr. Down fail to obtain a grave history of physical or psychical decadence from either progenitor. It might be necessary to examine the physical conformation of parents and grandparents. Disparity in the age of the parents might be a cause in some cases. Dr. Down has found that seven is the average number of living children born to those who have had an idiot child; prolific child-bearing appears to be a characteristic of people begetting feeble-minded children. Twin-births do not act as appreciable factors in the causation of idiocy. Dr. Down attaches immense importance to the emotional life of the mother during the period of gestation. The *physical health* of the mother also has an appreciable influence. One cannot fail to be struck with the nature of the stock from which idiots have sprung. "With fathers phthisical and irascible, with mothers feeble in judgment and so emotional that everything is a cause of fright, one is astonished that they should have procreated any sane child at all." Dr. Down has found it very difficult to get at reliable statements with regard to the influence of *alcoholic intemperance*. In the members of the upper ranks of the social scale it was an insignificant factor, but in the lower social classes a factor of great importance. Some cases are the result of deterioration of the father's mental and physical powers, others of procreation having taken place during a debauch. As to *malignant disease*, 3 per cent. of the fathers and 5 per cent. of the mothers, in all 8 per cent. of the progenitors, died from cancer. Goitre occurred in 2 per cent. of the mothers, but not once in a father. Syphilis is not an important factor in the production of idiocy. Dr. Down met with a history of epilepsy in 3 per cent. of the fathers and in 6 per cent. of the mothers. *Phthisis*, amongst progenitors, also exercises an important influence. This was most evident in the Mongolian type. In 23 per cent. of the cases there was a history of idiocy, mental feebleness, insanity, or other grave neurosis, in one or several of the brothers and sisters. The lecturer had known several instances of the father begetting healthy children except when suffering from recurrent mania, idiocy resulting to the children conceived at that time. In like manner Dr. Down knew of examples of healthy children being produced except when the merchant's business speculations have been hazardous, when the clergyman's parish has been disturbed, or the dissenting minister's church meetings have been stormy.

Although Dr. Down's patients came from every variety of social rank, he could not draw any safe deductions as to the influence of various occupations of the parents on the causation of idiocy. He had collected 400 cases with fair social antecedents, and had found that 75 per cent. were the children of merchants, county gentlemen, officers in the army and navy, gentlemen of independent means and liberal education, and members of the titled aristocracy. No less a proportion than 25 per cent. were the children of members of one or other of the three *learned professions*. Of these, 18 per cent. were the children of members of the clerical profession. Mr. Galton finds that the legal profession (which procreates fewest idiots) gives birth to 11 per cent. of the foremost men of eminence; that the medical profession (which procreates 1 per cent. more of idiots than the legal) gives origin to 9 per cent. of scientific men; while the clerical profession, which procreates the maximum amount of idiocy, gives birth to only 6 per cent. of men of science. These statistics illustrated the process of natural selection.

Dr. Down discussed at great length the subject of *consanguinity* in relation to idiocy. He is convinced that frequently the other possible factors have been neglected,

Digitized by Google

and this has led to very contradictory opinions. "Although, looked at superficially, my statistics are rather less favourable to the marriage of first cousins than are those of many other observers, I am strongly of opinion that, having regard to the remarkable antecedent neurotic history of the first cousins who have married and procreated feeble-minded children, the evil apparently resulting is, that where there is hereditary predisposition, the intermarriage of relations determines the concurrence of two morbid factors, and this may account for the undoubted greater frequency of feeble-minded children among the progeny of cousins than among those of mixed marriages."

Illegitimacy might be a potent factor in the causation if it entailed emotional disturbance in the mother during pregnancy. Attempted abortion might also have an influence. Idiocy is occasionally induced by deprivation of the senses. The case of a boy who was born only with the sense of smell and that of touch was narrated. The boy could "smell out" his friends, and manifested by a smile his consciousness of their proximity.

Cretinism might be caused by malarial poison. Some cases under Dr. Down's care were procreated during the intemperance of the father. Three of Dr. Down's cases of cretinism were males, and nine were females. He gave a *résumé* of the work of Billarger (1857), Dr. Hilton Fagge, Sir William Gull, Dr. Ord, Professor Kocher, and Victor Horsley on the relationship of cretinism to myxœdema and the thyroid gland.

Dr. Down entertains positive opinions as to the *higher culture of women*. He says: "If there is one thing more certain than another about the production of idiocy, it is the danger which arises from the culture of only one side of woman's nature. ..... There can be no reason why the faculties which they possess should not be cultivated so as to make them not only fit to be 'mothers of men,' but also companions and helpers. My statistics point to the importance of training our sons to be temperate, and our daughters to be self-possessed."

THE WHITE CORPUSCLE OF THE BLOOD.

A SUPPLEMENT TO MY REMONSTRANCE ADDRESSED TO PROFESSORS OF PHYSIOLOGY AND PATHOLOGY AGAINST TEACHING, IN THEIR WRITINGS, LECTURES, OR OCCASIONAL ORATIONS, THAT WHITE CORPUSCLES OF THE BLOOD EMIGRATE FROM THE INTERIOR OF SMALL VESSELS, UNTIL THEY HAVE VERIFIED IT BY ACTUAL OBSERVATION OF THEIR OWN AS A FACT IN NATURE.

BY T. WHARTON JONES, F.R.C.S., F.R.S.

THOUGH he still held that white corpuscles do emigrate through the walls of small vessels from the blood therein contained, Cohnheim latterly came to the conclusion that the escape depends on a passive filtration merely, and not, as he first supposed, on an active boring by means of processes which he alleged the white corpuscles shoot out even while the blood is still within the living vessels, in the amœboid manner they are seen to do in blood displayed under the microscope immediately that it is drawn.

Dr. Binz of Bonn,[1] however, maintains the validity of Cohnheim's first teaching, and, in support of it, adduces an experiment by which he thinks the white corpuscles of the blood within the vessels of the living part under observation can be rendered incapable of undergoing amœboid change of shape, and incapable therefore, according to him, of boring a passage through the vascular walls, so that emigration is prevented. This seems to be an inconclusive experiment, seeing that a reagent which could extinguish the irritability of white corpuscles is not likely to leave unscathed the other constituents of the blood and the integrity of the vascular walls. Suspension of the alleged capacity of white corpuscles to shoot out processes in an amœboid manner while the blood is still within the vessels might thus be owing to a change in the condition of their surroundings, as much as to change in that of the white corpuscles themselves. But, let it be asked, did Dr. Binz ever really see white corpuscles of blood, while still within the living vessels, shoot out processes in an amœboid manner under any circumstances, and by a teredinous action therewith make their way through the vascular walls?

Even if white corpuscles of the blood while still within the living vessels did undergo amœboid change of shape, what grounds are there for the supposition that the diverticular processes they shoot out do or could exert any boring action? The idea of a boring action, in fact, betrays an imperfect study of the nature of the amœboid phenomenon exhibited by the white corpuscles in blood newly drawn. The amœboid change of shape which the white corpuscles commence to undergo in blood immediately on being drawn seems to be really the result of partial contraction or collapse of the cell wall around the nucleus and contained protoplasm on one side, whilst on another side the wall is protruded here and there in diverticula. This takes place with a more or less evident jerk, and has been mistaken for an actual bursting of the corpuscle with evacuation of its contained protoplasm. There is, however, no such bursting of the corpuscle nor evacuation of the protoplasm.[2] Continuing to watch the corpuscle in its supposed burst state, we may see a diverticular process become more or less retracted in concurrence with a supervening diverticular protrusion of some other part of the cell wall which had been previously collapsed around the nucleus and protoplasm. Of the nucleus any defined view is prevented by the protoplasm.

The protrusion of a diverticular process is thus certainly not an active movement with force, like that of a proboscis fitted for a boring operation, as supposed. The phenomenon appears to be a last manifestation of the vital irritability inherent in the substance of the white corpuscles, excited by the altered condition in which the blood comes to be placed by abstraction from the living body. After the fibrin of the blood under examination is seen to have become deposited on the slide by coagulation from the plasma, the serum that is left seems to be received into the interior of the collapsed white corpuscles by endosmotic imbibition through their wall into the more consistent protoplasm, and distends them so far that they recover in some degree their round form.

In the course of our observations of the flow of blood in the vessels of a frog's web displayed under the microscope, a white corpuscle may often be seen to become adherent by a point of its surface to the wall of a vessel, and to be pressed into a pear shape, in consequence of the bearing of the passing stream on it while thus anchored. When the adhesion gives way, the white corpuscle, on becoming free, recovers its previous round form, and is carried along in the stream. This phenomenon, which is of well-known occurrence and obviously passive, has actually been described as a manifestation of an *active nibbling* on the part of the corpuscle by means of a process which it shoots out as a feeler for the purpose of finding a pore in the wall of the vessel through which to commence a boring operation in order to emigrate.

It is well known that when the white corpuscles of the blood are acted on by much diluted acetic acid, the protoplasm is dissolved out, and an object like several small nuclei adhering together brought into view. This object is commonly accepted as the *vera effigies* of what actually exists in nature before the abstraction of the protoplasm permits it to be seen. In my paper on the "Blood-corpuscle," in the Philosophical Transactions for 1846, it was, however, shown that the white corpuscle possesses in reality only one large nucleus, and that the appearance of several small ones aggregated together is owing to a corrugation of the cell wall of this single large nucleus by the action of the acetic acid of the dilution commonly employed. To prove that such is the fact, let water acidulated in the slightest degree only be used. Under the action of this, solution of the protoplasm will go on, though very slowly; but if we patiently watch its progress, a nucleus—single and large—will at last come into view.[3]

[1] Virchow's Archiv, vol. lxxiii.

[2] The protoplasm evacuated, as alleged, from the burst corpuscle was supposed to act as a ferment whereby coagulation of the blood was induced, but in disproof of this opinion there stands the fact that in the course of our observation fibrin is deposited by coagulation on the glass slide, though no such bursting of the corpuscles or evacuation of their contents is seen to take place.

[3] In histological research, reagents applied to the object under microscopical examination are often of great assistance by bringing into view details of structure and indicating chemical composition. As above shown, however, acetic acid corrugates the single large nucleus of the white corpuscle so as to make it appear as an aggregation of several small ones. From this example, a caution must be interposed against accepting the appearances disclosed by the action of reagents on tissues

Digitized by Google

In the course of my researches, I observed that the single nucleus of the white corpuscle of horse's and elephant's blood in particular was less susceptible of becoming corrugated under the action of acetic acid. Here I would particularly remark that the single nucleus of the white corpuscle of the blood of man and the mammifera corresponds in size and structure with the red corpuscle of the same blood; being, for example, very large in the elephant, in the blood of which the red corpuscles are very large; and, on the other hand, very small in the goat, in the blood of which the red corpuscles are very small; furthermore, inclining to an oval form in the alpaca, the red corpuscles in the blood of which are oval. It was for this reason, among others, that in my papers on the "Blood-corpuscle," in the Philosophical Transactions for 1846, I enunciated the view that the red corpuscles of the blood of the mammifera are homologous with the single nucleus of their white corpuscles.[4]

To return to the question of "emigratio." Although Cohnheim latterly abandoned the idea that emigration of white corpuscles from the blood is an active process, I do not know whether he continued to hold that white corpuscles, having passively escaped by filtration, do then commence to undergo amœboid movements, and thereby wander in the interstices of the tissues. If a minute section of the cornea be displayed under a microscope with a one-eighth of an inch object-glass, and attentively examined, no corneal corpuscles are at first seen at the cut edge. After a brief interval of time, however, corpuscles are observed to protrude as if filtering through interstices. Are these corneal corpuscles the objects which Cohnheim considered to be white corpuscles of the blood which had emigrated through the walls of vessels in the adjacent part of the conjunctiva and sclerotica, and which had, as he supposed, made their way by means of amœboid movements into the interstices of the cornea?

The gist of Cohnheim's doctrine, we have above seen, is that "emigratio" of white blood-corpuscles constitutes the first real characteristic step of the inflammatory process. The question, therefore, latterly agitated between Cohnheim and Linz as to whether emigration be a passive filtration or an active boring would be so far of secondary import in the pathology of inflammation, even if emigration pure and simple could be demonstrated. We have seen that "emigratio" has been accepted and taught as a fact by professors who seem never to have made any observation of their own relating to the subject. In the Hunterian oration at the Royal College of Surgeons some two years ago, the orator, in referring to John Hunter's sketch of the phenomena of inflammation, observed that if his hero had flourished in the present day he would have dwelt in a particular manner on the emigration of white blood-corpuscles, by virtue of their amœbiform endowments, through the softened walls of the small vessels and their further action on the tissues. Hunter, I am sure, would have done no such thing, but would have first said: "Let us see whether it be a fact that white corpuscles do emigrate at all, as alleged." Had the orator himself ever done this? Pity that some guardian angel had not roused him from the musings by which he was led to make such a suggestion, and whispered into his ear: *nil fingendum, nil excogitandum, sed inveniendum quod natura faciat—quod natura ferat.* That the walls of the vessels through which emigration is alleged to take place first become softened by inflammation, so that the white corpuscles are enabled readily to bore their way through, is an assertion in which the sequence of the steps formulated by Cohnheim is inverted, so that the gist of his doctrine of the inflammatory process is misrepresented; whilst his relinquishment of the idea of an active boring operation which he originally entertained is not mentioned.

"Softening by inflammation," which Mr. Marshall, in his Hunterian Oration under notice, alleged to be a state of the walls of the vessels which permits of a boring of the white corpuscles therethrough, is a mere gratuitous assumption, and, as we see, inconsistent with Cohnheim's teaching. The expression "softened by inflammation" might, however, be admitted as applicable to the softening and disintegration of structure to actual disappearance of the vascular walls, as originally observed and described by myself in cases of intense inflammation of the frog's web, whereby white corpuscles were left free and unenclosed in any wall, but forming, by their aggregation, succedaneous walls of a venous channel, through which the blood was seen still flowing. This observation was quoted in my "Remonstrance" from my essay in Guy's Hospital Reports for October, 1850. Had Mr. Marshall read this?

The characteristic which especially distinguished John Hunter as a scientific man was his subjecting the physiological and pathological questions that came before him to the test of observation and experiment. The suggestion, therefore, that he would have dwelt on "emigratio" in elucidation of the question of the pathology of inflammation on the mere assumption that it was a fact, made by Mr. Marshall in his oration, was like putting in a plea for Cohnheim's doctrine (though at the same time misrepresenting it) under the sanction of John Hunter's name. Such a suggestion, however, was disparaging rather than eulogistic of the hero of the day, and may be compared, conversely, to the divided eulogy of Harvey on the occasion of the unveiling of his statue at Folkestone in 1880, when Mr. (now Sir Richard) Owen, taking advantage of his position as inaugural orator, virtually claimed a place on Harvey's pedestal for the glorification of John Hunter also—a proceeding something like the cunning manœuvre of Richie Moniplies (subsequently dubbed "Sir Richard") in Sir Walter Scott's novel of the "Fortunes of Nigel," who enclosed in his master's petition to King James I., which he had been sent to deliver, a "sifflication" of his own.

The scepticism as to "emigratio" being a fact in nature evinced in my "Remonstrance" on the question has been called "comical"; perhaps the strictures now made may be accounted "pragmatical," though (to adopt Bishop Bedell's aspiration) I hope good men will not so account them. Hereto may be added, now I think of it, that my volume containing two lectures against the Darwinian hypothesis of evolution,[5] which had been delivered in the botanical theatre of University College to large audiences of ladies and gentlemen, was noticed in the *Saturday Review* at the time of publication in the following words, and no more: "The author is angry, and it is not very scientific to be angry." This short and easy criticism—this shirking the question under review and levelling a flippant personality against the author—was an *ignoratio elenchi*, aggravated in its meanness and dishonesty by being anonymous.

Ventnor, Isle of Wight.

ON A CASE OF EMPYEMA,

WITH REMARKS ON THE MANNER IN WHICH PERFORATION OF A BRONCHUS IS BROUGHT ABOUT.

By C. J. BOND, F.R.C.S.,
HONORARY SURGEON TO THE LEICESTER INFIRMARY.

IN making a post-mortem examination some time ago in the case of a young man who had died suddenly with symptoms of empyema discharging through the lung, the condition found was sufficiently interesting to suggest the following remarks.

A. B——, a previously healthy lad, aged fourteen, was admitted into the hospital with a history of an attack of pleurisy, with effusion, of sudden onset, and of a month's duration. Some ounces of clear fluid were drawn off by aspiration. A week later, however, the patient was seized with dyspnœa, during which he coughed up a quantity of thin, purulent fluid. The pleural effusion had, in fact,

---

as an exact representation of the details of structure actually existing in nature. Prepared structures mounted on slides—such as sections, vascular injections, &c.—are for the most part mere toys. It must always be borne in mind that the dissection of minute objects by manipulating under the simple microscope, whether for further examination with a higher power under the compound microscope or not, can never be superseded by the examination of ready-made specimens mounted on slides.

[4] It is to be remembered that the large nucleated red corpuscles of the early mammiferous embryo are homologous with the nucleated red corpuscles of the oviparous vertebrata. See my papers referred to for details in regard to this and my discovery of large nucleated corpuscles in the blood of grown mammifera, especially the horse and elephant, some with the cell wall slightly tinged red, and some with the cell wall wholly uncoloured, and as pale nearly as the almost invisible cell wall of certain oval nucleated corpuscles (the nuclei very strongly marked), observable in the blood of the frog, which I described and delineated forty years ago in the Philosophical Transactions, but which have of late years been "rediscovered"—to adopt a euphemism.

[5] Evolution of the Human Race from Apes, and of Apes from Lower Animals—a Doctrine unsanctioned by Science. London, 1876.

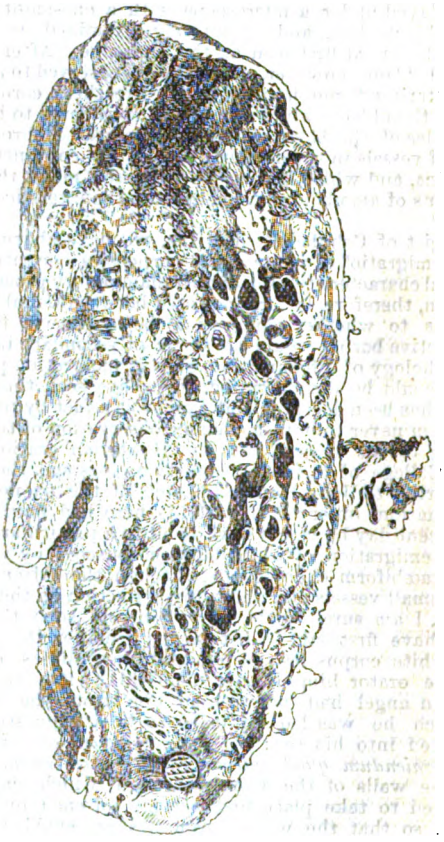
become purulent, and had perforated a bronchus. The patient died shortly afterwards.

Necropsy.—The right pleural cavity contained some ounces of thin offensive pus. The lung was collapsed—in fact, compressed from apex to base against the spine, the heart, and opposite mediastinum. Below the level of its root, just at the rounded and compressed posterior border, and close to the spine, was a depressed area the size of a penny, which contained numerous depressed openings. A section of the lung at right angles to the surface over a part of this area (Fig. 1) showed that several wedge-shaped portions of lung tissue had necrosed, partially and irregularly filling corresponding cavities (D) in the lung parenchyma. These necrosed portions of tissue (C) were still in continuity with the pleura (B) covering them, but in several places that membrane had also given way, thus leaving the depressed openings mentioned above; in other places the lung tissue had sloughed under the pleura, so that this latter alone remained, forming a thin septum between the pus of the empyema and the cavities in the lung. Finally, the cavities communicated at their central or narrower ends with several small bronchi (E).

Something more than mere perforation of an air vesicle and

FIG. 1



Section of lung at area of perforation (from photograph). A, Compressed lung. B, Pleura. C, Necrosed lung. D, Cavity. E, Piece of string through bronchus, communicating with cavity.

bronchus by the fluid had evidently occurred. A portion of lung tissue, owing to the pressure upon it, or to plugging of its vessels and arrest of its vascular supply, or possibly to inflammatory changes, had sloughed. Further, the fact that the pleura remained intact in several places, although the lung tissue beneath it had necrosed so thoroughly as to leave a cavity, suggested that the necrotic change preceded the perforation of the serous membrane, and the entrance of the pus; in fact, it seemed as though the necrotic change itself determined the site of the perforation. If, on the other hand, the perforation of the air vesicle occurred first, subsequent inflammatory and destructive changes in the lung, might be caused by the filling of the alveoli with pus; but it has always seemed difficult to understand why a collection of fluid pressing equally on the lung surface should cause perforation, unless there be also some primary change in the lung tissue itself, which would allow of its more easy destruction and so determine the site of the opening. It appears to me that the condition here described strongly suggests such a preliminary change in the lung tissue. Microscopical examination of the lung tissue immediately around this area showed a marked pneumonic change, while at a distance of a quarter of an inch the lung appeared healthy, though compressed.

A further very important point for consideration is the situation of the perforation in the lung. Mr. Marshall has shown that when an empyema perforates the chest wall, the tendency is for it to do so in front—namely, between the fifth and sixth costal cartilages, where the muscular interspaces are thinnest and weakest. Now in cases of empyema which I have observed, in which perforation of a bronchus has occurred, the collection of pus has been chiefly at the posterior part of the chest, and often limited to that area by pleural adhesions—being shut off, of course, from the anterior part of the thorax, where the chest wall is thin. In fact, it would appear that the seat of election for perforation is, in front, in the case of the chest wall, and in the case of the lung, at the back, somewhere near the posterior border and below the level of the root. The following observation may suggest an explanation of this fact. If a vertical antero-posterior section be made of a lung compressed by pleural effusion (Fig. 2), it will be seen that the larger tubes, both bronchi and pulmonary vessels, are arranged in a closely packed semicircle, with its convexity towards the spine; further, that this line

FIG. 2.

Vertical section, from before back, of lung compressed by pleural effusion (from photograph). Section passes at right angles to entrance of bronchus, and shows openings of bronchi and vessels arranged in a semicircle, with its convexity backwards towards spine.

of the openings of the tubes, is considerably nearer the posterior than the anterior border of the lung, and also that the tubes are more closely packed below than above. Any pressure therefore exerted on the lung tissue from without, as in the case of an empyema, would act most powerfully on this portion of the lung, compressing it against the rigid bronchi, which lie at this spot just beneath the surface, while, in addition, the thickness of the elastic cushion is less, and the distance between the surface of the lung and an air-tube of any size is shorter here than in other parts of the lung. In confirmation of this belief, I would observe that if, on the contrary, pressure be exerted on the lung tissue from within, as by the forcible injection

Digitized by Google

of water into a bronchus, perforation or rupture generally occurs near the anterior or thinner margin, probably owing to the fact that at this part, in most adult lungs, there is more or less emphysema, with consequent weakening of the walls of the alveoli. Speaking generally, then, an empyema situated at, or having access to, the front of the chest, will, if left alone, discharge by perforation of the chest wall; whereas one occupying the back part of the pleura will probably under similar conditions perforate the lung.

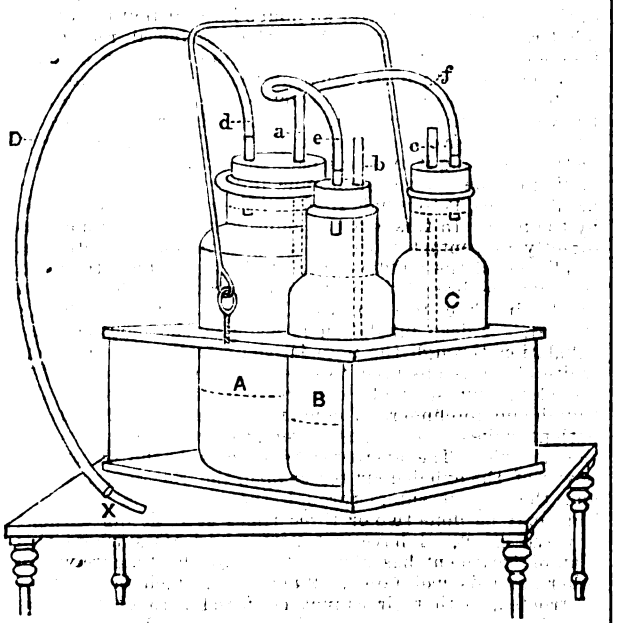
There is one other point in connexion with these cases to which I should like to draw attention. In many or most of the cases of empyema in which an opportunity has occurred of tracing the disease from beginning to end, the affection evidently commences in pleurisy with serous effusion, the fluid gradually becoming more and more turbid, until in a few weeks perhaps the purulent stage, or true empyema, results. The cause of this change would appear to be as follows, at any rate in some cases. The thick deposit of exudation composed of leucocytes and fibrin which occurs on the surface of the lung becomes partially or wholly detached owing to the shrinking and movements of the lung, and remains as shreds or sheets of loose membrane in the serous fluid in the pleural cavity, as may be found if the contents of the cavity be evacuated by an early incision and the interior explored with the finger. It seems probable, then, that these flakes act as foreign bodies, and by constant irritation bring about the conversion of a serous into a purulent effusion. Moreover, as these membranes take a long time to break up and disintegrate, they constitute one of the difficulties in the after-treatment of the case, often lying as they do below the level of the incision. In children, on the other hand, it is far more common to find the effusion purulent at an early stage in the history of the illness; it is thicker, more like the pus of an ordinary abscess, and is generally present soon after the onset of the inflammatory symptoms.

ON THE USE OF CHLORIDE OF AMMONIUM AS AN INHALATION IN DISEASES OF THE RESPIRATORY TRACT.

BY KENDAL FRANKS, M.D., F.R.C.S.I.,
SURGEON TO THE ADELAIDE AND THE THROAT AND EAR HOSPITALS, DUBLIN.

CHLORIDE OF AMMONIUM has been extensively used as a therapeutic agent, and its value in many affections of the mucous membrane of the throat has been very widely recognised. That such is the case is amply proved by the many forms of lozenges or so-called compressed "tablets" containing the salt which are more or less in vogue. In this form it has been found most useful in catarrhal conditions of the fauces and pharynx; but its use in posterior nasal catarrh, rhinitis, and catarrh of the Eustachian tubes and of the middle ear, as also in affections of the larynx, trachea, and bronchial tubes, has not been so encouraging, and the reason of this no doubt is that in the form of the powder, dry or in solution, or made into lozenges and given by the mouth, the salt cannot act locally on these regions, but only through the general system, and under such circumstances the benefit to be derived from its administration is more than doubtful. In order to overcome these difficulties and to extend the local use of the chloride to these less favoured regions, advantage has been taken of the fact, long since recognised, that the combination of the fumes of hydrochloric acid with ammonia gas at once forms a white smoke, which consists of chloride of ammonium in a finely divided state. This forms the basis upon which all chloride of ammonium inhalers are framed. The great therapeutical advantages to be derived from the chloride in this state has been long known and valued by throat and aural specialists; but general practitioners, as a rule, do not seem to have appreciated the good results which may be looked for by the judicious and regular use of the inhalation of chloride of ammonium. The cause of this probably has been the complicated nature of the apparatus often used to develop the vapour, the liability of its getting out of order or of its breaking, and the uncertainty as to the vapour containing the neutral salt alone, or perhaps also containing free hydrochloric fumes or free ammonia. The vapour (I employ this term here to express the white clouds formed by the junction of the fumes and the gas) when neutral is almost tasteless and perfectly unirritating, and it is in this form that it is of greatest use. Free acid I consider is always bad; a little free ammonia is not of much consequence, and is often of use. The method of detecting either the acid or the ammonia in the vapour I shall allude to again. Add to these objections the trouble of charging the inhaler with fresh acid and ammonia each time it is used, and we shall have a sufficient explanation of the reason why the inhalation of chloride of ammonium is not more popular among the members of the profession generally. For many years I have used this salt in this form extensively both in hospital and private practice, and have at different times tried most of the inhalers designed for developing it. I therefore venture to call attention to that form of inhaler which I believe will be found most simple and the most easily and satisfactorily managed, and also to point out the various classes of cases in which its use is most indicated.

I have found the best results to follow the inhalation of chloride of ammonium in chronic catarrhal conditions. In acute catarrh it does little good—at least, when the disease is once fully established; but in the beginning of an acute catarrh I believe it will be found often to check its further progress. I have known it to be so in my own case, and have been greatly gratified to find the symptoms of a cold in the head disappear after an hour's intermittent use of the inhaler. In chronic catarrh of the post-nasal region, so frequently associated with deafness, due either to chronic otitis media or to obstruction of the Eustachian tubes—a condition sometimes very intractable to ordinary means—I have found the regular use of the inhaler for weeks or even months give the most satisfactory results. The best method of using it in nasal catarrh, or in chronic inflammation of the mucous membrane lining the nasal or post-nasal regions, is to inhale freely by the mouth and to exhale by the nose. In this way the chloride of ammonium comes directly in contact with the affected parts. In catarrhal conditions of the middle ear or of the Eustachian tube the salt can be brought directly to bear upon these parts by having recourse to Valsalva's method of inflating the ear. A deep inhalation is made by the mouth; then exhalation through the nose is begun, and as soon as the white cloud is observed to emerge from the nostrils they are closed by suddenly compressing them between the thumb and forefinger. The mouth is firmly closed, and the patient makes an effort, as it were, to force the air through the nostrils. The apertures being closed, the distending power of the exhaled air forces open the Eustachian tubes, and the vapour enters through them into the tympana. This may be done two or three times at a sitting without any evil effect. I have met with many cases where this plan of treatment has alone sufficed to effect a cure where other methods had failed. When the Eustachian tubes are obstructed, so that air cannot be forced through them by Valsalva's method, the occasional use of Politzer's bag during the earlier part of the treatment will usually suffice. In chronic laryngitis, especially of the catarrhal form, chloride of ammonium inhaled is of great value. In the early stages of that form of laryngitis which so often accompanies phthisis, when there is erosion of the mucous membrane covering the inter-arytenoid fold, or when there is chronic inflammation of the vocal cords themselves, I have seen good results follow from this vapour, more especially when combined with some volatile oil, such as oil of eucalyptus or pine oil, in a manner I shall immediately describe.



Again, much benefit may be derived from its use in affections of the trachea and bronchial tubes. Some years ago I prescribed it for an elderly gentlemen who was confined to his room in the beginning of winter for a chronic cough. He had been liable to chronic bronchitis every winter, which kept him in-doors for several months. Most of the usual remedies had failed with him, so at last I determined to try the effect of chloride of ammonium as an inhalation. He was directed to use it three times a day for fifteen minutes at a time. In a fortnight he was sufficiently well to go out, and the use of the inhalation during the winter prevented the return of his bronchial trouble.

The best method of inhaling in laryngeal or bronchial cases is much the same as is used by smokers in inhaling from cigarettes. A mouthful of the vapour is first taken, followed at once by a deep inspiration of ordinary air; this

Digitized by Google

carries the chloride well down into the bronchial tubes. If this is not done, the vapour may perhaps not travel beyond the pharynx.

The apparatus for developing the chloride of ammonium which I prefer to all others is the Burroughs Improved Chloride of Ammonium Inhaler (Vereker's patent), a drawing of which is annexed. As it is comparatively of recent date, I may be excused for shortly describing its *modus operandi*. It is essentially composed of three bottles connected together by tubing. The two smaller bottles (B and C) contain respectively solutions of ammonia and of fuming hydrochloric acid. I have found that the pure commercial acid acts the best. The pure acid of the British Pharmacopœia is scarcely fuming enough, and is much more expensive. Each of these bottles is provided with an india-rubber cork, with two perforations each. Through one of these holes passes down in each case a glass tube (*b* and *c*), open at each end. This should dip down well into the fluid in the bottle. Two short tubes pass through the other holes. These should only reach to just below the cork. The outer end of each of these short tubes is connected by means of indiarubber tubing (*e* and *f*) with a glass tube (*a*). This glass tube reaches down nearly to the bottom of the bottle A, and its upper extremity terminates in a cross tube open at both ends, to which are attached the ends of the tubes *e* and *f*. The bottle A contains water, which should

fill about one-third of it. A short glass tube also passes through the rubber cork of the bottle A, but does not extend beyond it into the bottle. To the outer end of it is attached a long rubber tube (D), with a mouthpiece (X) attached to its free end. This tube (D) is usually made too short for convenience, and I generally advise patients to procure a long piece of tubing. When the tube is short the patient has to hold up the inhaler, and is incapable of doing anything else during the time of inhalation; but with a long tube the inhaler can be placed on a table beside him, and the patient can read or write all the time, and thus a more regular use of the inhaler is probable. From the foregoing description it will be seen that when the patient inhales through the tube D, a vacuum is formed in the bottle A, and the air in the bottles B and C rushes in to take its place through the tubes *f*, *e*, and *a*. These bottles are again replenished with air through the tubes *b* and *c*. As the air passes down through the tubes *b* and *c*, it bubbles up through the ammonia and acid in B and C respectively, and consequently becomes charged with their vapours. These vapours meet in the tube *a*, and at once form chloride of ammonium. The air charged with this salt bubbles up through the water in A, and is thus washed before it is inhaled through D. When exhaled it is seen to emerge as a dense white smoke. Now, in order that this should be neutral—that is, that the vapour should contain no free acid or ammonia—it is essential that the bottles B and C should contain the proper proportions of their respective fluids in equal volumes. Suppose C contains half an ounce of pure commercial hydrochloric acid, B should contain half an ounce of equal proportions of the ordinary solution of ammonia and water. Should this be found too strong, a little of it may be poured out and the same quantity of water added. If it be too weak, less water and more ammonia should be used. A little practice will make the patient expert in regulating the proportions. The acid bottle should not be interfered with unless the acid has become so weak as to require to be changed for a fresh charge. I have generally found that the acid will not require to be changed oftener than once in two months. On the other hand, the ammonia is so volatile that it will require strengthening, perhaps once a week, sometimes more frequently. The plan I adopt myself is simple. When I have found that the charge of ammonia has become disproportionately weak, I add two or three or five drops of strong solution of ammonia to it, until I find the vapour has become quite neutral. I have already said that the vapour inhaled should be perfectly unirritating. I have found from experience that when the ammonia is too strong it causes a smarting sensation at the back of the *pharynx*. When, however, the acid is in excess—that is, when the ammonia is too weak—the vapour chiefly affects the *larynx*, when a burning feeling accompanied by *coughing* and sometimes a sensation of choking is experienced. This affords, then, a good guide as to whether the ammonia should be strengthened or weakened. Another point deserves attention, and that is that the ammonia, being so much more volatile than the acid, has a tendency to pass over through the tube E into the water in the bottle A, and thus the vapour when passing through the water may take up an excess of ammonia gas. This is easily obviated by changing the water in A every second or third day. When it is considered desirable to add any other substance, such as oil of eucalyptus, to the vapour to be inhaled, the simplest and best plan is to add every day, say, five drops of the oil to the water in the bottle A. As the vapour bubbles up through this water, the oil globules become agitated and broken up, and the vapour carries with it a very sensible amount of the volatile oil. I have found this extremely useful. A great advantage which this form of inhaling these oils possesses is that they are inhaled cold, and therefore the patient is not exposed to the risk of catching cold, if obliged to leave the house shortly after inhaling.

I believe that if this inhaler be more largely tried in general practice, it will be found that all I have said in its favour, more particularly as to the results of its use, will be found to be borne out by individual experience.

Dublin.

VENEREAL DISEASES IN GIRLS OF TENDER AGE.

BY FREDERICK W. LOWNDES, M.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL LOCK HOSPITAL AND LIVERPOOL POLICE.

OF all the cases in which medical evidence is required, few, if any, are less inviting than those in which men are charged with criminal assaults on females of tender age. To a conscientious medical witness who has carefully perused the chapters on rape in the various medico-legal works of Casper, Taylor, Ogston, Guy, and Tidy, the responsibility appears to be very great; for any remissness on his part to state every circumstance which may be favourable to the accused on the one hand, or to strengthen the case for the Crown on the other, may be productive of the most serious consequences. In the former case it may lead to the conviction of a man who is perfectly innocent of the crime with which he is charged, and his sentence to penal servitude for a considerable portion of his future life; while in the latter case it may assist in the acquittal of a guilty man—guilty of as vile an offence as a man can be guilty of. In addition to this grave responsibility, the details and surroundings of these cases are of so gross a nature that, as a learned judge (Justice Wills) recently remarked in his address to a grand jury, "men of mature life could hardly wade through the mass of iniquity which he had to struggle through in these matters without feeling himself degraded and poisoned by their perusal."

If any apology were needed for this paper, I trust that its heading will be sufficient. The subject was brought to my

Digitized by Google

notice in a very prominent manner immediately after my election (more than eleven years ago) as surgeon to the Lock Hospital. The very first female patient admitted under my care was a diminutive girl whose age was stated to be twelve years, who looked even younger, but who was really just over thirteen. Since then other cases of infected children have been brought to the hospital, making up to the present date a total of twelve cases. There are two points to which I would wish to direct special attention. The first is that under existing circumstances we can hardly expect a reduction in the number of these offences. For as the recently passed Criminal Law Amendment Act now makes carnal knowledge of a female under thirteen years of age a felony, and under sixteen years a misdemeanor, even with her consent, it naturally follows that this Act has created a new class of felonies and misdemeanors. The other point is that in all these cases there was some evidence of infection with gonorrhœa or syphilis, and in at least three of them it was clearly proved that the accused persons who were suffering from a similar disease hoped to effect a cure by having sexual intercourse with their victims. This horrible superstition still prevails largely in Lancashire as in other parts of England, and as it must from the very first have proved to be as false as it is filthy, it is lamentable to observe how long it has prevailed. So far back as 1827 the late Dr. Gordon Smith alluded to it in his Principles of Forensic Medicine (3rd edition, page 413), and most writers on forensic medicine allude to this superstition more or less briefly. Thus Casper says: "It is well known that among the lower classes there prevails an absurd and horrible opinion that a venereal complaint is most certainly and quickly cured by coitus with a pure virgin, and most indubitably with a child, and this explains the very numerous cases observed by us."[1] Taylor says: "There is a vulgar error prevalent that gonorrhœa in the male is cured by sexual intercourse with a female virgin; and this error is said to be the cause of the frequency of the crime of rape on children in England."[2] Tidy says: "In a very large proportion of the cases sent for trial the victims are young children. There are several reasons for this. One is the popular superstition that if a man suffering from gonorrhœa have intercourse with a virgin he will be cured. Disgusting as it may seem, it is no less a fact that old women doctresses not unfrequently prescribe this criminal attempt to young men who consult them for urethral discharges. Many cases recorded show this to be the fact."[3]

The following is a summary of the cases which have been seen in the Lock Hospital within the last eleven years:—

No.	Date.	Name.	Age.
			Years.
1	May 20th, 1875	M. McD——	13
2	August 11th, 1876	M. E. S——	11
3	August 24th, 1881	S. A——	12
4	August 24th, 1881	G. S——	9
5	December 14th, 1881	H. S——	12
6	March 20th, 1884	A. C——	14
7	July 24th, 1884	E. R——	11
8	September 11th, 1884	M. E. M——	7
9	September 18th, 1884	E. A. Y——	12
10	September 14th, 1885	M. H——	5½
11	February 16th, 1886	J. A. G——	9
12	March 30th, 1886	A. H——	14½

At the present date (Oct. 18th) we have in the female wards a girl aged thirteen suffering from ulcers of the labia under Dr. Bernard's care. There are also two imbecile females in my ward, one suffering from syphilis, the other from vaginal discharge. In none of these cases can the offenders be prosecuted.

Besides these, I have seen other cases in private practice. In one which was brought to me by the late Mr. Higginson, a girl was infected with syphilis by, as was stated, a lad whom she met in the street one Saturday afternoon. Mr. Higginson had informed a police-inspector of the case, but the lad was wholly unknown to the girl, and she could give no satisfactory description of him.

In all the cases of syphilitic infection the disease was most amenable to treatment, a mild mercurial course, and soothing applications to the primary ulcers producing a most marked improvement in a very short time. For condylomata yellow wash acted extremely well after a previous application of lead and opium lotion. The vaginal discharges readily yielded to cleanliness and alum injections carefully applied by the nurse.

There remains to be noticed a very important matter upon which much difference of opinion still exists. I refer to the right of a medical practitioner to examine an accused person at the request of a magistrate or police official. I have never done this without the permission of the person charged, given in the presence of at least one witness. Moreover, I have always, in addition to obtaining his consent, fully explained that the result might be in his favour or against him, but that whatever it might be I was bound to state it. If after this full explanation he consents, I have no hesitation in examining him. Although the consent of the accused is mentioned as requisite in both Taylor's[4] and Tidy's[5] works, there are members of our profession, barristers, and police officials, who appear to hold a contrary opinion. In view of the almost epidemic form of actions against medical practitioners, which we are still experiencing, it appears to me to be of paramount importance not only to decline to make any compulsory examination, but to be absolutely certain that consent is given, not in ignorance, but in full knowledge of all the consequences.

In conclusion, I would wish to say that, while the experience of all the foregoing cases shows how little reliance could be placed upon the statements of at least some of these girls, it is perfectly clear that what is now considered a misdemeanour was committed upon all of them, while in nine cases they were under the age of thirteen, which makes it a felony under the existing law. I fear that there are many other cases (where fortunately for the females there has been no infection with disease) which do not come to light. In this city all such cases are most severely scrutinised before they are sent to trial. Then the grand jury, acting under the direction of the judge, are quite prepared to throw out the bill in any case which appears to them to be a weak one. Lastly comes the trial itself. The judge, the counsel on both sides, and the men who compose the common jury are all fully aware how easy these charges are to make and how difficult to disprove. A calm dispassionate review of our judicial system as regards these cases will, I think, convince most medical observers that it is admirably adapted to fulfil its purpose: to prevent, on the one hand, any man from being put upon his trial for a groundless or weakly supported charge: and, on the other hand, to punish severely those men who commit such cruel outrages on children of tender age.

PURULENT ENCEPHALITIS WITH OBSCURE SYMPTOMS OCCURRING IN A PREGNANT WOMAN AT FULL TERM;

CHILD SAVED BY ABDOMINAL SECTION (PORRO'S OPERATION).

BY W. ALEXANDER, M.D., F.R.C.S.,

VISITING SURGEON, LIVERPOOL WORKHOUSE HOSPITAL.

ELIZABETH W——, aged twenty, was admitted to the division for pregnant women of the Liverpool Workhouse on Oct. 14th, 1886. She did not complain of anything on admission, but was regarded by the other women in the division as "distant and snappish," and when spoken to would tell the speaker to "mind her own business" and "not to bother her." She complained to the doctor on duty on the 16th of headache, but she said it was not much, and probably owing, she thought, to the onset of labour. On Oct. 18th she was taken to the lying-in wards on the suspicion of labour having commenced, but it was found to be a "false alarm." Next morning she went again, but no signs of labour presented themselves. She then seemed to the midwife to be quite well. On the evening of the 19th she looked restless before retiring to bed, but did not complain, and during the night she got up several times to drink water. Towards the morning, on returning from the water-bottle, she fell three times across the beds that intervened. The nurses from the lying-in wards were then sent for, and found the patient in a "hysterical" convulsion, confused in her manner, but quite conscious except when "working" in her fits.

Digitized by Google

On Oct. 20th, as I was going through the lying-wards of the hospital on my usual rounds, my attention was called to this patient, who was still in the pregnant women's division. Her face was somewhat congested, she was slightly unconscious, and was suffering from irregular convulsive movements that seemed partly voluntary and partly involuntary. No signs of labour were to be found, but she seemed to be at full term and the fœtal movements were very distinct. The substance of the history just given was then told to me. The case was diagnosed as one of puerperal convulsions occurring during pregnancy, and probably caused by a debauch. As her bowels had been already moved, and as she could not swallow, a rectal injection of thirty grains each of chloral and bromide of potassium was prescribed, to be repeated according to necessity.

I visited the hospital again in the afternoon, at 6.30 P.M., and found that the coma had deepened very much during the last half-hour; the convulsions had become more decided and epileptiform, affecting chiefly and primarily the face and arm centres for the left side, but extending often into a storm that involved the whole body. The eyes gave the faintest response to pressure, and the pulse was scarcely perceptible. Mustard to the legs, frictions, &c., had been tried without effect, and Dr. McMurray, who had watched the case carefully during the day, had already come to the conclusion that the patient was dying. A short examination convinced me that he was right, and that the "status epilepticus" into which the patient had fallen was one from which she was not likely to recover. The child was still moving, but less vigorously than at midday, and it was evident that whatever was to be done would have to be done quickly. An examination per vaginam showed that the os uteri was still firmly closed, that the vagina was dry and undilated, and that there was an entire absence of any signs of labour. The removal of the child *per vias naturales* would, it seemed to me, be too slow to save the child and relieve the mother. Abdominal section offered the best chance, especially as I am quite familiar with and very successful in the performance of this operation for various diseases. Nurses were immediately detailed to wash the woman with warm soap-and-water and with corrosive sublimate solution; the spray was got in readiness, and the sponges that are always kept at hand for an "emergency" abdominal section were brought to the lying-in ward, as this ward is very clean and was then fortunately empty of any case in labour.

The uterus was exposed by an incision four inches long. Through the uterine walls the placenta could be seen adherent to the part just beneath, and over the placenta some large veins were distinctly visible. Dr. McMurray kept the abdominal wall closely applied to the uterus, and surrounded the opening I was about to make into the uterus with sponges. This opening I made in a longitudinal direction for two inches in a spot free from large veins. A gush of venous blood was the result of the incision. This was immediately stopped by the insertion of two fingers into the uterine wound. By means of these two fingers the placenta was stripped off the uterus, and on their withdrawal the hæmorrhage had ceased. The opening was now enlarged upwards and downwards until a sufficient opening was made to enable the placenta and afterwards the child to be removed. As the child was removed Dr. McMurray expressed the womb outside the abdomen, thus closing the abdominal walls around the organ, so as to completely shut the abdominal cavity and protect the intestine. All this had been done without chloroform and without a movement of the patient. The midwife now took charge of the child and placenta, and the question was what was to be done for the mother. The screaming of the child that we now heard showed that *one* life was saved. I was disappointed that the operation had not roused the patient, which I had hoped it would, and Dr. Blackwood had been standing by ready with chloroform and watching for any sign of consciousness. As the woman was young, and all the internal organs healthy, I would have liked to have stitched the womb up and left her undeprived of any organ; but this operation would have taken time, and would have allowed some risk from hæmorrhage, which might have destroyed any remaining chance of life, and the chance seemed already a very desperate one. I therefore quickly performed a "Porro," and, covering the abdominal wound with antiseptic sponges, endeavoured to resuscitate the patient. Stimulants per rectum, subcutaneous injections of ammonia and ether, artificial respiration, galvanism, &c., were tried for about an hour, but the failing pulse gradually disappeared and death ensued.

Next morning a sister of the deceased told us that the latter had led an intemperate and profligate life, and had been beaten just before admission.

An examination of the body showed slight contusions, but none greater than she might have obtained during the convulsions. On opening the skull, a thin layer of pus was found beneath the dura mater, covering the whole of the encephalon, and extending down to the base of the skull. There were no signs of any injury to the brain or skull; the lungs were congested, and all the organs showed signs of excessive indulgence in drink, but otherwise they were healthy.

The baby is a plump healthy girl, who takes to her bottle with avidity, and seems to enjoy the life into which she was so tragically ushered.

When I was house-surgeon at the Workhouse Hospital in 1873, a woman was brought in suffering from convulsions. Just as my colleague, the late Dr. A. M. S. Hamilton, saw her, for the purpose of locating her, she had a sharp convulsion, and died in the cab. We immediately took her into the nearest room and performed Cæsarean section. A fine, well-formed, well-matured infant was removed, but quite dead. In my last case the result has been better, although I was disappointed that the coma did not yield to the stimulation of the operation. Had the coma depended merely upon essential puerperal eclampsia, the operation, the gush of blood, and the emptying of the uterus might have done good, and saved mother as well as child. The imperfect history of the case obtained before death, and the latency of the symptoms before convalescence set in, did not prepare us for the startling lesion found at the necropsy. Altogether, I do not think any improvement could have been made either in the time of the operation or the kind of operation, and a fuller knowledge of the case would not have secured any better results.

ON A CASE OF

TRAUMATIC TETANUS SUCCESSFULLY TREATED BY THE SUBCUTANEOUS INJECTION OF MORPHIA.

BY J. FALCONER MURISON, M.B., C.M. ABERD.

ONE of the most appalling and fatal maladies to which man is liable is traumatic tetanus. The following case, which came under my care nearly twelve months ago, will, I think, be of some interest to the profession.

On Jan. 29th, 1886, I was sent for to visit a young man whose "jaws were stiff and would not open." I found him in bed, complaining of great stiffness in his jaws, and a peculiar feeling when he attempted to swallow food or drink. He was twenty-six years of age, over six feet in height, and powerfully built. On questioning his parents I elicited the following facts: On Jan. 15th he was engaged, along with a servant lad, carting manure from the farmyard to the fields. He asked the lad to hand him a spade, which he (the lad) at once took up and threw towards the patient. The distance between them was only six yards, and the spade struck the patient severely on the inside of the left knee-joint, causing at the time excruciating pain. The part was badly bruised, but although in severe pain the patient continued at his work all that day. In the evening the pain increased and the knee-joint became swollen and stiff. For the following ten days he was confined to bed, during which time he constantly applied fomentations and poultices to the knee. The swelling and pain disappeared, and he resumed his ordinary duties, feeling nothing whatever the matter with him, until the 29th, when the first symptoms of tetanus made their appearance.

When I first saw this young man he was suffering intensely. The jaws were firmly clenched, and he experienced some difficulty in swallowing. The muscles of the temples, jaws, and neck were stiff and rigid, the features were fixed, and the countenance expressive of acute pain. Risus sardonicus was well marked, giving a comical expression to the face. I saw at once that I had to deal with a very serious case, and, as the patient was lying on a bed in the farm kitchen, I had him removed at once to a cool, quiet, and airy bedroom, a screen being drawn round his bed and perfect quietness enjoined. His temperature was 104°, his pulse 90, and his body covered with free perspiration.

Digitized by Google

The treatment consisted of thirty grains of hydrate of chloral, with twenty grains of bromide of potassium, given every four hours. This was continued for three days, at the end of which time the patient was in no way benefited; he did not even sleep. The symptoms increased; the muscles of the back and legs became involved; and during the paroxysms opisthotonos was well marked and excruciating pain felt at the pit of the stomach. Tincture of cannabis Indica was then tried, the dose being fifteen minims at first, gradually increased to half a drachm, with inhalation of nitrite of amyl. This was also given every four hours and continued for three days, at the end of which time there was still no improvement visible to the patient. Ice was applied to the spine, and he was put under the influence of chloroform twice a day for an hour at a time. Still the paroxysms continued as bad as ever, if not worse, and as the patient had got little or no sleep for the previous week, I determined to try the effects of morphia. I therefore injected subcutaneously one grain and a half into the muscles of the right thigh, and awaited the result. In about half an hour he was dozing, and continued so for about two hours. On awaking he felt himself greatly relieved, and begged hard to have the injection repeated, as he was unable to suffer such severe pain. The medicines were now all discontinued and the subcutaneous injections of morphia thereafter solely relied on. For four days one grain was injected every four hours, for the next two days every six hours, and the next two days every eight hours. Then, as the symptoms gradually disappeared, the injections were used less frequently, until at the end of the third week only one grain was injected at night, with an occasional half-grain through the day. During the fourth week only half a grain was injected at night, and during the fifth week only every alternate night. At the end of the sixth week the patient was convalescent, and was able to be out of bed and to do without the morphia. During the whole time of his illness, which extended over a period of six weeks, his nourishment consisted of beef-tea in a concentrated form, milk, switched eggs, soups, wine, and brandy, all being given freely.

I think this case will interest not a few, owing to the marked benefit the patient derived from the subcutaneous injections of morphia, after the usual remedies—chloral hydrate, bromide of potassium, cannabis Indica, ice, &c.—had been thoroughly tried and completely failed to relieve him of a single symptom of this terrible disease. So much am I convinced of the benefit accruing from the use of morphia in this particular case that, were I called upon again to treat another case of a similar nature, I should have no hesitation whatever in beginning the treatment at once with a full dose of the solution of morphia injected hypodermically.

MIDDLESEX HOSPITAL.

PYLORECTOMY FOR CARCINOMA; DEATH; NECROPSY.

(Under the care of Mr. HENRY MORRIS.)

THE following instance of operation for carcinoma of the stomach, in which the growth was situated at the pylorus, appears to have been performed in one of those cases which are especially adapted for the operation of pylorectomy. The growth was limited in extent, free from adhesions to the surrounding parts, there was no affection of the glands in secondary deposits, and the patient was comparatively young, being only thirty-nine years of age. The progress after operation was for a time satisfactory, and although the patient died, few surgeons of experience would hesitate to adopt the same line of treatment in a similar case in preference to the alternative operations of gastro-enterostomy, duodenostomy or jejunostomy, which are only palliative. For the report of the case we are indebted to Mr. W. Roger Williams, surgical registrar.

The patient, a very emaciated woman of dark complexion, aged thirty-nine, was admitted under the care of Dr. Finlay on July 9th, 1885, with the following history:—She has suffered from dyspepsia since youth. Symptoms of the present disease began nine weeks ago with an attack of jaundice, which lasted for a month. During this illness constipation, nausea, and vomiting were marked symptoms, and have continued so ever since. A month ago she first noticed a "lump" in the upper part of the abdomen, which was much the same size then as now. During the last five weeks she has lost much flesh. She has never had good health. In addition to dyspepsia, she has frequently been subject to a hacking cough, with much expectoration, and shortness of breath. Twenty years ago she had rheumatic fever. She married at twenty-six, and has had seven children, four of whom died in infancy, and of the others one has a "weak chest."

On admission she complained of a sinking feeling at the pit of the stomach, constipation, and flatulence, with nausea and vomiting after taking food. The bowels had not acted for a week. The conjunctivæ were slightly yellow, but there were no other signs of jaundice. On examination of the abdomen, a freely movable, hard, nodulated mass, the size of a hen's egg, was felt a little above and to the left of the umbilicus; sometimes its position shifted to the right of the umbilicus. There was dulness on percussion over the tumour, to which all her pain was referred. The tumour was not affected by movements of the chest. The liver dulness extended from the sixth rib to the costal margin; the splenic area was normal. The urine was free from albumen, and its specific gravity 1016. A loud blowing bruit, which replaced the first sound of the heart, was heard at the apex and at the angle of the scapula. A loud systolic bruit was also heard over the second right costal cartilage. After admission the vomiting continued, and on July 20th she ceased to retain nutrient enemata. Death from starvation seemed imminent.

At a consultation on July 24th it was decided to make an exploratory abdominal section, with a view to pylorectomy, in the event of the tumour being free from important adhesions, and the adjacent glands &c. uninvolved; otherwise gastro-enterostomy or jejunostomy was to be done.

On July 26th and 27th the stomach was washed out with a warm weak solution of boracic acid. This was repeated on the morning of the 28th, shortly before commencing the operation. At 9.30 A.M., assisted by Mr. Gould and Mr. Paul (the house-surgeon), Mr. Morris proceeded to open the abdomen by a longitudinal incision, four inches long, made a little to the right of the umbilicus and having its centre over the tumour. On opening the peritoneal cavity, the enlarged and hard pylorus was at once reached. It was quite free from adhesions, and was readily withdrawn through the wound. No enlarged glands could be felt, and the adjacent parts seemed normal. The omentum above and below the diseased part was ligatured with two rows of catgut sutures, and then divided between the rows. The pylorus and the adjacent parts of the stomach and duodenum being thus completely freed from their omental connexions, a flat sponge was placed beneath the diseased area, and the division of the stomach was then commenced at the small curvature and carried obliquely downwards and to the right, just along the anterior and then along the posterior surface for about half the distance between the great and small curvatures. All bleeding points on the cut surface being stopped by pressure forceps, the incisions were extended by a succession of short snips. As soon as the stomach was sufficiently laid open, its contents were removed by the introduction of sponges on long forceps; thus extravasation of its contents into the peritoneal cavity was avoided. Before completing the section of the stomach some occlusion sutures were introduced. As soon as the separation of the stomach from the diseased mass had been completed, a couple of silk loops were passed through its sero-muscular coats, and the cut edges were retained outside the abdomen whilst the separation from the duodenum was being effected. Finally, the divided duodenum was united to the stomach by numerous sutures, the posterior ones being introduced first. Part of the duodenum, through which the section passed, was devoid of peritoneal investment; so that in effecting the union of the divided viscera, for a certain extent, the apposition of serous surfaces was interfered with. This

Digitized by Google

was a circumstance of importance, because it was in this situation that the sutures subsequently ulcerated through and allowed extravasation into the peritoneal cavity. Lembert's method was alone employed for the first ring sutures, and Lembert's alternating every three or four with Gussenbauer's suture for the occlusion suturing. The operation lasted nearly two hours and a half.

The patient was a little sick after returning to bed. Enemata of port wine (three ounces) and peptonised beef-tea (three ounces) were given alternately, the first port-wine enema being administered two hours after the operation. During the afternoon and evening she complained of intense thirst, and a teaspoonful of iced water was allowed by the mouth at intervals. There was a slight motion of the bowels at 6.30 A.M., one hour after a port-wine enema, and again slightly at 8 P.M., when she passed eight ounces of urine. Evening temperature 100·4°; pulse 120. During the night she slept for about six hours and a half.

On the morning of July 29th she still complained of intense thirst, for which a teaspoonful of iced barley-water was given from time to time. This she retained. The enemata were continued every four hours, and five minims of liquid extract of opium were added to the beef-tea injections to assist their retention. There was a slight motion of the bowels; no sickness. Morning temperature 98·6°. She passed another fairly good night.

July 30th.—She still complained of great thirst. Temperature 99°. Six ounces and a half of urine passed during the last twenty-four hours. Enemata retained; no vomiting. At 9 P.M. the bowels acted freely, the motion being of a dark-grey colour. Rectum irritable, and the enemata but partially retained. During the day she slept for about six hours. At 10.30 P.M. she vomited about half a pint of dark-brown odourless fluid, and again at 1 A.M. She slept for about six hours and a half during the night.

31st.—Morning temperature 98·6°. She has passed seven ounces of urine during the last twenty-four hours. Most of the enemata are retained. At 11.30 A.M. she complained of a sharp pain in the epigastric region, screamed loudly, and then vomited several times. At 1.30 P.M. the wound was dressed for the first time; it looked normal; the sutures were not disturbed. During the afternoon the patient continued to complain of pain in the abdomen; she was sick at intervals, and the enemata were not retained. At 9.30 P.M. she was very weak and much changed for the worst. She still vomited occasionally. Temperature 101°. During the night she had no sleep, was very restless, and died in a state of collapse at 4 A.M. on August 1st.

Necropsy, ten hours after death.—Body exceedingly emaciated. The peritoneal cavity contained about eight ounces of sero-purulent fluid. There was recent acute general peritonitis, the intestines being injected and glued together by recent lymph. The left lobe of the liver was adherent to the anterior surface of the stomach. The stomach occupied a position that was almost vertical; it was small and contained some fluid. On close examination of the operation lesion, it was found that all the occlusion sutures and all the ring sutures that were on the peritoneal aspect were quite secure and well embedded in lymph. It was at the posterior and upper part of the wound, near where the occlusion sutures joined the ring sutures, that some of the latter had ulcerated through and allowed the gastric contents to escape. These were found occupying a small pouch immediately behind the gap. There were no cancerous glands adjacent, and no secondary deposits in other parts of the body. The lungs were small and emphysematous. There were old pericardial adhesions. Both auriculo-ventricular valves were competent, but they presented much old thickening. The aortic valves were thickened, calcareous, and incompetent. The heart was rather large. Both kidneys were small and granular.

WEST LONDON HOSPITAL.

CASE OF PARTIAL PARAPLEGIA, PROBABLY DUE TO SYPHILITIC MENINGITIS; RECOVERY; REMARKS.

(Under the care of Dr. DONALD W. C. HOOD.)

C. H——, aged twenty-eight, a stonemason, was admitted on Jan. 18th, 1886. He complained only of great weakness in both legs. He was unable to walk more than a few yards. He dated his illness from the evening of the 24th ult., when he had felt much fatigue after a short walk, and had stiffness and cramps in the calves of both legs. During the preceding week he had had seminal emissions every night, and irritability of the bladder night and day. From the morning of the 25th up to the day of admission the weakness in his legs rapidly became more and more marked. He was unable to retain his urine longer than an hour at a time. The patient was a strong, muscular, healthy-looking man. He had had no previous illness of moment, but had suffered from a chancre some seven years before. The chancre was not followed by sore-throat or by any constitutional trouble. There was great loss of power, equally distributed in both lower extremities. He could barely move his legs as he lay in bed, and could only stand or struggle along a few yards with the greatest effort and fatigue. There was complete loss of all reflexes below the abdominal; if anything, these were in excess. The cremasteric were entirely absent. The limbs were muscular, and there was no wasting. Sensation appeared perfectly normal, and the patient made no complaint of pain. The spine was carefully examined, but no trace of bone disease could be discovered. The muscular power of the upper limbs and trunk appeared natural. On the supposition that the patient was suffering from syphilitic inflammatory mischief he was at once placed on iodide of potassium and perchloride of mercury. Under this treatment the patient made rapid progress towards recovery, recovery being, however, impeded by a sharp attack of tonsillitis, which at that time was almost endemic in the hospital. The first indication of improvement was the lessened irritability of the bladder; then muscular power returned by degrees, the patient being able to move and turn in bed without effort. A month after admission there was some return of plantar reflex, the patellar and cremasteric being still absent. The patient could now stand without difficulty, and could walk across the ward. A month later the muscle power was noted as being fairly normal, and within a few days the patient was discharged as well.

Six weeks subsequently the patient reported himself as well as he had ever been, and able to walk any reasonable distance without fatigue. At this time there was still no patellar reflex.

Remarks by Dr. HOOD.—There can be but little doubt that the lesion in the above interesting case was a circumscribed inflammation of the spinal meninges, lying somewhat above the lumbar enlargement of the cord. The inflammatory mischief was probably gummatous in character, and must have been limited to the anterior portion of the cord, the substance of which could scarcely have been affected, looking at the rapid and perfect restoration of muscular power. I conclude that the inflammatory products involving the internal surface of the dura mater compressed the anterior surface of the cord and implicated the motor roots.

BURTON-ON-TRENT INFIRMARY.

CRUSHED PELVIS; RUPTURE OF THE BLADDER; NECROPSY; REMARKS.

(Under the care of Mr. MASON.)

FOR the following notes we are indebted to Mr. A. P. Trinder, house-surgeon.

Thos. P——, aged thirty-six, was admitted on Nov. 1st, 1886, at 6.30 P.M. The patient, a powerful man, a shunter in one of the yards, was riding on the spring of a waggon, when passing some points, on which he had himself placed some trucks without allowing proper space between them and the main line, he was caught by the buffer of the nearest one on the left hip, twisted round by it, and so crushed that his hips passed transversely through a ten-inch space. Having passed the obstacle he fell, and was immediately brought to the infirmary by his mate, who, being behind him on the same waggon, saw what occurred and saved himself. The patient was never unconscious.

On admission, the hands and feet were slightly cold; body warm; pulse regular, and of fair volume; temperature 98·4°. The man complained of great pain in the hypogastrium. The perineum and left hip were slightly bruised and painful, but not much swollen. He could not lift his thighs without assistance, especially the left. He asserted positively that he had passed urine within an hour of the accident. Mr. Mason saw him, and on account of the pain passed a No. 8 silver catheter, which entered the bladder easily, but, to his surprise, drew off bright-red blood. The catheter was kept in. An ice-bag was applied over the

Digitized by Google

pubes, and beef-tea and ice were given by the mouth. He was also ordered twenty minims of liquor morphiæ, which was repeated later on.

Nov. 2nd.—Very little sleep last night; body warm; pulse quiet, of fair volume; temperature 99°. Taking iced milk and beef-tea pretty well. Pain diminished; no pain in the abdomen on pressure, except over the pubes; no dulness on percussion anywhere except over the bladder, which reached two inches up. The catheter has drawn off a considerable quantity of bright blood and urine. A consultation was held as to operating, but delay was advised, as the hæmorrhage had abated and his condition was good.

3rd.—Slept well; temperature last night 101°; to-day 100°. Catheter blocked with clot, and exchanged for a soft red rubber instrument; very little blood, and of a blacker colour. Bowels cleared out by enema.

6th.—Doing well; sleeps and eats fairly. Catheter drawing nearly clear urine, but has been often blocked by clots. Bladder repeatedly washed out with 1 in 300 carbolic solution, as the urine smells very foul. Temperature 101·2°; pulse 120.

8th.—Doing well, except that he had another smart hæmorrhage from the bladder to-day. Perineum rather more swollen and discoloured, but not prominent as in ruptured urethra. Temperature 100°; pulse 120, steady. At 3 P.M. another consultation was held, but the hæmorrhage having again ceased, it was considered advisable to leave him alone, as it would probably be impossible to control the bleeding vessel, which was supposed to be the internal pudic artery ruptured by a fracture of the pelvic ramus. Very foul gas escapes along the catheter.

9th.—Slept all night. Takes food better. Catheter drains well; no more hæmorrhage. Temperature last night 101°; to-day 99°. On pressure over the right side of the pubes emphysematous crackling can be plainly felt, and foul gas is expelled from the urethra. For fear of infecting the ward, he was carried, mattress and all, into a small special ward, without experiencing any pain or producing any hæmorrhage. At 9 P.M. he had a rigor, and the temperature was 102·5°. Mr. Mason made two small incisions—one in the perineum, which led nowhere, the other over the crepitating region to the right of the pubes, the latter incision giving vent to horribly offensive gas and urine, which dribbled slowly on syringing through the catheter. At 3 A.M. the temperature was 103·6°, and the pulse 160, weaker, slightly irregular. Two ounces of brandy ordered.

From this time the patient lost ground in spite of a large amount of fluid food and from two to four ounces of brandy daily. The temperature ranged from 101° to 103·8°, and the pulse from 120 to 150, and becoming smaller and weaker. Two small hæmorrhages occurred, and diarrhœa ensued, followed by death on Nov. 17th. The smell during the last week was overpowering, in spite of sanitas and carbolic sprays.

No regular post-mortem examination was made, but the pubic wound was enlarged to admit two fingers, when it was discovered that the pelvis was fractured in three places—viz., the symphysis pubis and the right and left body and descending rami of the pubes. The triangular fragment on the right side was found pushed backwards and downwards into a rent in the bladder wall as large as an egg. The silver catheter could be felt lying against the bare bone of the pubic arch, the soft parts of the neck of the bladder being destroyed. The right triangular fragment was easily removed through the wound and carefully examined. The fracture through the body of the pubes ran right through the obturator notch, so that in all probability it was the obturator artery which was ruptured and caused the hæmorrhage, and not the internal pudic, the more so that the fracture of the descending ramus ran in a slanting direction through it, coming out at the arch of the pubes, and leaving the lower or perineal border attached to the ischium.

Remarks by Mr. TRINDER.—The points of interest in this case seem to be that the patient should with such a severe injury (1) show so little sign of shock, (2) live seventeen days, (3) have his bladder ruptured in an empty condition, and (4) bear carrying from one room to another without pain or hæmorrhage. A median or right lateral cystotomy (which was several times proposed and postponed) would have allowed freer drainage and cleansing, but at the same time would have tended to increase the hæmorrhage by removing the beneficial pressure exercised, in all probability, on the ruptured vessel by the large body of clot which was known to be present. The operation could not have enabled us to control the hæmorrhage effectually.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Hypertrophy of Bladder.—Lipoma of Heart.—Spontaneous Disintegration of Vesical Calculi.—Infantile Palsy.

AT the ordinary meeting of this Society held on Tuesday last, Sir James Paget, F.R.S., President, delivered his presidential address on taking the chair. This will be found *in extenso* at page 159. The meeting was a very large one. Sir Joseph Lister proposed, and Dr. Samuel Wilks seconded, the vote of thanks for the address.

Mr. E. HURRY FENWICK showed a frozen section of a Hypertrophied Bladder, removed from a patient suffering from stricture of the urethra, who died of intercurrent disease. The specimen demonstrated the greater thickness of the anterior wall as compared with the posterior. In this case the anterior wall was twice the thickness of the posterior. He believed this condition, which obtained in hypertrophied bladders, had been overlooked, and the reason for its want of recognition was due to wasting of the muscular wall after the stricture had been relieved, and cases of unrelieved stricture were rarely found on the post-mortem table. He adduced anatomical proofs to support the theory that it is the anterior wall which possesses the greater power of hypertrophying, and he submitted that the comparatively greater strength, elasticity, and resistance to pressure of the anterior wall was one of the reasons for its acknowledged greater immunity in ruptures of the urinary bladder.—Sir JAMES PAGET said that, so far as he knew, the communication supplied a new fact.—Mr. JAMES BLACK suggested that the anterior wall became hypertrophied because it offered more resistance to muscular contraction than the posterior.

Dr. HANDFORD showed a specimen of Fatty Tumour of the Heart, and said there was no satisfactory example of a true lipoma of the heart in any of the nineteen principal museums in the kingdom. There are, however, three doubtful specimens, two of which are probably examples of fatty overloading, and the third is classed among "tumours of uncertain origin." They are in the museums of the College of Surgeons of England, St. Bartholomew's Hospital, and Queen's College, Birmingham. So far as he could ascertain no such specimen has been shown at the Pathological Society of London. The recorded cases only number three, one of which (Gernet's) is doubtful. The three cases are: 1. By Albers, in Virchow's *Archiv*, Bd. 10, p. 215. (1856.) 2. By Gernet, in Virchow's *Archiv*, Bd. 42, p. 534. (1867.) 3. By Banti, in *Lo Sperimentali*, tom. lviii. (Sept. 1886.) He was indebted to Mr. Evan Powell, medical superintendent of the Nottingham Borough Asylum, for the specimen, as also for the notes of the case and of the necropsy. Unfortunately, only the tumour and the inter-auricular septum in which it was embedded have been preserved. The patient was a woman aged seventy-six, who died during sleep. At the necropsy there was found a fair, but not excessive, amount of subcutaneous fat. There was no fatty tumour or excess of fat anywhere, except around the heart, which weighed 14 oz. The muscular substance of the heart was very pale, and of a yellowish colour; it felt greasy and looked streaky to the naked eye. In the inter-auricular septum was a hard round substance about the size of a small pigeon's egg. It was distinctly limited, but had no definite capsule. When cut it had all the appearance of an ordinary fatty tumour. The liver was fatty, but the other organs were apparently healthy. There could be no doubt of the distinctness of the growth, or of its fatty nature. From the appearance of the tumour, from its position in the septum between the auricles, and from the observations of Mr. Power at the necropsy, he entertained no doubt that it was not an instance of the burrowing inwards of the subpericardial fat. A microscopic examination showed that the tumour consists of fat cells with a few degenerating muscular fibres scattered here and there. The probable origin of the tumour was in the inter-muscular connective tissue.

Dr. W. ORD showed fragments of Vesical Calculus, which had resulted from spontaneous disintegration, and had been passed the last few months by a gentleman, aged seventy-five, who for six years had had sugar in varying quantity in his urine, and albumen also. Free uric acid in large crystals were also passed. Six months ago the left femoral artery became blocked, and sloughing of the skin of

Digitized by Google

the left leg was observed. And three months ago he began to pass calculous fragments without pain and with but little bleeding. A soft catheter had to be introduced as much for enlargement of prostate as for calculous obstruction. The detached fragments evidently came from an ovoid calculus one inch in length. Some fragments had rounded margins, having been chipped off some time before being ejected. Dr. Ord had shown five specimens of spontaneous disintegration of calculi, so it was doubtful whether this process was of rare occurrence. There were two ways in which disintegration could occur: either from within or from without, as in the present specimen. The chemical composition was uric acid and urate of ammonia, and the parts were probably not originally firmly put together; the remarkable alterations in specific gravity of urine might be compared in their effects to alternations of comparative drying and moistening. This was the best explanation he could offer.—Sir JAMES PAGET had seen similar specimens.

Dr. SEYMOUR SHARKEY read a paper on Infantile Palsy, dealing chiefly with the final stage. The specimens were removed from an old man aged sixty, who died of epithelioma of the œsophagus. The legs had been paralysed for fifty-eight years. All the muscles of both legs were represented by masses of fat showing numerous pinkish streaks running longitudinally. The lumbar part of the spinal cord was much wasted. The microscope showed innumerable corpora amylacea. The large nerve cells were reduced in size and number; there were a great many nuclei, and the groundwork of the anterior horns had a finely fibrillar texture. The walls of the vessels had a hyaline appearance, with abnormally large perivascular spaces. All the white columns were shrunken, but the antero-lateral strands seemed to have undergone greater diminution than the others. The larger nerves, shown in transverse sections, presented a great number of healthy nerves intermixed with islands of atrophied axis cylinders surrounded by the sheath. The muscles consisted chiefly of fat, but here and there a few perfectly healthy fibres, well striated, were seen. Other sections were shown from an earlier stage of infantile palsy; in some of these there were to be seen parallel wavy rows of sarcolemma nuclei.—Dr. SAMUEL WILKS said that the case corroborated the views he had always held.—Mr. W. ADAMS spoke of the value of the communication.—In reply to Mr. R. W. PARKER, Dr. SHARKEY said there were no obvious secondary changes in the cortical motor centres.

The following card specimens were exhibited:—Dr. Handford: Œsophageal Malformations, Fistulæ, and Carcinoma. Dr. Sharkey: Syphilitic Arteritis. Dr. H. Maudsley: Ulceration of Trachea, with Perforation of Aorta. Dr. B. O'Connor: Mediastinal Tumour. Mr. F. Treves: Melanotic Sarcoma.

CLINICAL SOCIETY OF LONDON.

Athetosis and Aphasia in a Child—Treatment of Cysts of Thyroid.—Treatment of Imperforate Anus.

THE annual general meeting of this Society was held on the 14th inst., Mr. Thomas Bryant, F.R.C.S., president, in the chair. The list of officers for the ensuing year is appended to this report. The scrutineers of the ballot were Dr. S. Phillips and Mr. G. R. Turner. The votes of thanks to the retiring president (Mr. Bryant) and surgical secretary (Mr. R. J. Godlee) were warmly accorded. Mr. Christopher Heath, the treasurer, read the report of the finances of the Society.

Dr. SAMUEL WEST read notes of a case of Right-sided Hemiplegia with Aphasia, occurring in a female child. The hemiplegia came on suddenly during a paroxysm of whooping-cough. Slight rigidity developed in the weakened limbs, which had recovered some power, but of late athetosis as described by Dr. Gowers had developed. Hæmorrhage was the probable cause of the hemiplegia, but the locality of the lesion could only be surmised.—Dr. RADCLIFFE CROCKER related the case of a girl, aged ten, in whom there was a condition of athetosis and spasm of the right hand. There was a history of right-sided fits, three in number, and lasting over twelve hours. Hemiplegia followed, and about six weeks later the athetosis developed. The child had mitral disease, and the hemiplegia was probably of embolic origin.—Dr. BROADBENT thought that the fact that athetosis had been associated with lesions about the great ganglia should not outweigh certain considerations pointing to a cortical lesion. The remarkable difference in the limbs at rest during sleep and during waking without permanent contractures seemed to point to functional activity of the cerebral cortex. If paralysis had had more the type of a monoplegia, the cortical origin would be still more probable.—Dr. S. WEST had preferred not to suggest the pathology, but thought that the seat of the lesion would rather be in the internal capsule than cortex, considering the sudden onset of hemiplegia and subsequent spasm.

Mr. MAYO ROBSON (Leeds) read a paper on a Method of Treating Thyroid Cysts, in which he advocated antiseptic incision and stitching the edge of the cyst to the skin, draining for a short time under an antiseptic dressing, and then packing with zinc lotion and lint. He read notes of two cases thus treated, the first in a young woman, aged twenty-two, who had a cyst the size of a Tangerine orange over the trachea, which occasionally produced dyspnœa; the second in a woman, aged twenty-four, in whom the right lobe of the thyroid was forming one large cyst. In both the above treatment was perfectly successful, and produced no constitutional or local disturbance. When seen some time afterwards there was very little trace of scar, and no tumour in either case. He quoted from several standard surgical works to prove that the usual operations for thyroid cysts, such as injection, seton, &c., are either dangerous or unsatisfactory, and thought that the advantages of this method were its simplicity, safety, and certainty.—Mr. CHRISTOPHER HEATH said that the contributor had said nothing about hæmorrhage, which he knew from personal experience could be pretty severe from the interior of the sac. He did not know the reason for this; but the injection of perchloride of iron and plugging with strips of lint soaked in the perchloride succeeded very well in arresting the hæmorrhage. Perhaps in Mr. Robson's cases the cysts were so small that no hæmorrhage occurred.—Mr. GANT said that under no circumstances would he interfere with the interior of the cyst. Tearing or scraping of the same should be considered dangerous.—Dr. S. MACKENZIE had examined many microscopical preparations of these cysts, and the thin-walled vessels were remarkably numerous. Doubtless this anatomical fact accounted for the hæmorrhage, and perhaps for the beneficial effect of the perchloride, as testified by Mr. C. Heath. Iron was better than iodine to stanch bleeding.—Mr. H. H. CLUTTON corroborated Mr. Heath's remarks as to the liability to abundant hæmorrhage. He never thought it necessary to suture the skin to the cyst wall. In some cases of plugging the opened cyst high fever developed; the use of iodoform gauze obviated this tendency. The suture to the skin had an objection, in that it might cause the sinus to remain open, as in one case which continued three years. He would prefer complete excision of the cyst to scraping its walls.—Mr. T. BRYANT supposed that Mr. Robson did not claim that free incision was a new treatment, but that stitching the capsule of a cyst to the skin was. If this were not adequately done, septic matters might escape into the subcutaneous tissues. The fear of hæmorrhage would be an argument in favour of laying the cyst open, and making a sinus. In a case of puncture of a cyst, free incision and plugging were required to control the bleeding. In another case, in which Mr. Bryant injected a mixture of tincture of iodine, iron, and alcohol four times without untoward results, the fifth injection was followed by the development of a tumour that pulsated like an aneurysm. Fortunately, however, the application of an ice-bag reduced the swelling without further trouble; but a large artery had probably been tapped. With regard to Mr. Robson's operation, he considered that scraping the interior of such cysts was a bold form of practice.—Mr. MAYO ROBSON advised the suture to the skin as shutting off all the surrounding cellular tissue and preventing inflammatory extension. He would not practise complete excision again; in one case asphyxia, and in another hæmorrhage caused great anxiety. Further, the surgeon could not know how much of the gland would have to be removed, and in view of the functions of the thyroid, as expounded by Horsley, its removal was not advisable. He practised sufficient scraping to separate all colloid material, but not to extend deeply into the wall of the cyst.

Mr. MAYO ROBSON also read a paper on a Suggested Method of Operating on a Uniform Principle in the Treatment of Imperforate Anus, with example, and gave extracts from several authors to prove that the recognised treatment

Digitized by Google

of cases where the bowel is not soon reached is to perform either Littré's operation or colotomy, although the mortality of the operation, judging by published statistics, is extremely heavy—e.g., M. Guersant having operated in this manner twelve times without saving a patient. He advocated an incision from the central point of the perineum to the coccyx, and then a careful dissection, until either the bowel is reached or the peritoneum is opened, when the upper end of the rectum or the sigmoid flexure of the colon can be brought down and sutured to the skin in the anal region. He described a case in a child one day old, on whom, in March, 1866, he had performed this operation with a very good result, the child recovering without a bad symptom, either local or general, and when seen last the infant had what appeared to be a normal anus, through which a motion was passed about once a day. He considered the operation ought not to be very difficult if a catheter were introduced into the bladder and a good horizontal light were available; that it should not be very dangerous either from shock, peritonitis, inflammation, or hæmorrhage; and that the result, if successful, was infinitely preferable to that of Littré or a colotomy.—Mr. R. J. GODLEE related a case of imperforate anus which seemed to show that the meconium was by no means so irritating to the peritoneum as ordinary fæces were. The trocar in this case, it was found, had passed through the peritoneal cavity before puncturing the rectal cul-de-sac. Colotomy was successfully performed. The child died some time later from disease unconnected with the surgical operations.—Mr. HARRISON CRIPPS remarked that he had listened with much interest to Mr. Robson's paper, for he himself had collected and published in the St. Bartholomew's Hospital Reports the results of operation in over a hundred cases of imperforate anus. With regard to the statement quoted by Mr. Robson, on the authority of a foreign author, that there was only one case on record of recovery after Littré's operation for imperforate anus, the statement was entirely erroneous, Mr. Cripps mentioning that in his own paper five cases of recovery were described. He remarked that there were two chief varieties of imperforate bowel—the one in which there was no sign of an anus, the skin stretching unbroken from the perineum to the coccyx; the other in which the anus existed, but terminated in the cul-de-sac. In the former the rectum was generally near the skin, and much more likely to be found than in the latter class of cases. By making the dissection well backwards, and even, if necessary, following Verneuil's practice of resecting the coccyx, the bowel could generally be found and opened without cutting through the peritoneum. Mr. Cripps considered the dragging down of the rectum and stitching it to the skin a great mistake, for it hardly ever united, while the pus and discharge became pent up behind the stitches, and then set up the cellulitis and peritonitis which were the chief causes of death in these cases.

The following living specimens were shown:—Dr. Radcliffe Crocker: Athetosis after Hemiplegia in a Child. Dr. Stephen Mackenzie: A case of Chyluria with Filariæ Sanguinis. Dr. Angel Money: Hemiplegia with Spasm in a Syphilitic Idiot.

The following is a list of officers for the ensuing year:—President: W. H. Broadbent, M.D. Vice-Presidents: Sir Dyce Duckworth, J. Hughlings Jackson, Samuel Wilks, Sydney Jones, Howard Marsh, and Sir Henry Thompson. Treasurer: Christopher Heath. Council: R. E. Carrington, S. Coupland, F. G. D. Drewitt, J. K. Fowler, W. B. Hadden, F. de Havilland Hall, Felix Semon, F. C. Turner, W. J. Tyson, S. West, H. H. Clutton, W. H. Cripps, H. T. Butlin, A. Pearce Gould, R. J. Godlee, C. H. Golding-Bird, W. A. Meredith, W. Rivington, and John Wood, F.R.S. Honorary Secretaries: Stephen Mackenzie and R. W. Parker.

HARVEIAN SOCIETY.

A MEETING of this Society was held on Thursday, Jan. 6th, Dr. J. Hughlings Jackson, F.R.S., President, in the chair.

The Analogy between Croup and Asthma.—Dr. MORTON read a paper on this subject, the object of which was to compare stridulous laryngitis—to which he gave reasons for thinking the name of croup should be confined—and "spasmodic" asthma, with a view to their mutual elucidation. He called attention to the resemblance in the sudden nocturnal invasion; the diurnal remissions and recurrences for two, three, or more nights; the liability to repeated attacks; the greater prevalence in the male sex; the dry, early, and moist later stages; the cessation of the liability to croup, as well as to asthma, beginning at about six years of age; the frequent origin of both in slight catarrhal or peptic disorder; the common occurrence of both in summer as well as winter. All these peculiarities showed that croup could not be a real laryngitis with paralysis according to the commonly accepted pathology, but a paroxysmal dyspnœa from disturbed innervation of the larynx, as asthma was of the bronchi. This left it open whether the disturbance was motor or trophic. Sir Andrew Clark's hypothesis of fugitive quasi-erectile swellings of the mucous membrane afforded as complete and adequate an explanation of croup as it did of asthma. It was further suggested for inquiry whether hay fever, croup, and asthma might not be different expressions of the same state forming really one and the same disease.—Dr. CHARLES WEST observed that children who had been the subjects of croup or stridulous laryngitis in their earlier years were more prone to suffer from true asthma in later life. The child asthma, as a rule, ceased almost entirely before puberty, and this point should be especially borne in mind by practitioners, since it was possible that the rule might not hold good in cases where the general health of the child was not carefully maintained. Croup was essentially spasmodic in its nature, but was frequently caused by sudden variations of temperature, by attacks of slight catarrh, and by errors in diet. In croup the phenomena were those of spasm and something else; in laryngismus stridulus the spasm was the principal feature, a distinctive difference being formed by the catarrhal signs in the former. He thought that for the present it would be advisable to retain the term "stridulous laryngitis" as he could not altogether renounce the view that some form of congestion or inflammation of the larynx was generally associated with it.—Dr. GOODHART referred to the replacement of croup and stridulous laryngitis by asthma in later life, and inquired whether any corresponding replacement occurred in the case of child asthma after its subsidence at the period of puberty.—Dr. HUGHLINGS JACKSON, after remarking on the great value of Dr. Morton's paper, spoke of laryngismus stridulus and also of convulsions in cases of spasmodic laryngitis. He believed that these fits, and probably those occurring in pneumonia and other acute diseases of children, were owing to discharges beginning in parts of the medulla oblongata or pons Varolii; in other words, they were dependent on discharges beginning in parts on the lowest level of evolution, which was pretty much the "true spinal system" of Marshall Hall. He thought it a matter of great importance to note the mode of onset, the march of the convulsions, in these cases, as carefully as most people now do in cases of epileptiform seizures originating from the middle level of evolution (the so-called motor regions), and as we ought to do in cases of epilepsy proper, dependent, as Dr. Jackson believes, upon discharges from the highest level of evolution. Bearing in mind Victor Horsley's researches, we should, among other things, carefully note the nature, tonic or clonic, of the spasm in the different regions convulsed in the convulsions of children. He stated again a hypothesis he had put forward regarding the convulsions of laryngismus stridulus.[1] He thought they were owing to discharges beginning in the respiratory centres determined by supervenosity of the blood by an excess of their natural stimulus. That convulsions could be produced in some lower animals by inducing supervenosity and by rapid bleeding was well known; in these cases the convulsion is respiratory, and is probably owing to absence of oxygen. According to Kussmaul and Tenner, convulsions in rabbits are produced by rapid bleeding when the cerebrum proper is taken away. Laryngismus stridulus occurs in children at an age when the respiratory apparatus is imperfectly developed, and most often in those who, from rickets, have soft ribs; moreover, the attacks usually come on during sleep, when respiration is less active; these are conditions favouring supervenosity. The good effects of fresh air, country air, and cold sponging are in favour of this hypothesis; moreover, some authorities highly praise musk and belladonna, which drugs are respiratory stimulants; spasmodic asthma in the child and adult was, he supposed, a respiratory convulsion owing to the discharge of imperfect (? small) respiratory centres from supervenosity.—Dr. WEST added that both asthma and croup appeared to affect males more fre-

[1] Brain, April, 1886.

Digitized by Google

quently than females, while in other nervous affections, such as chorea, the frequency was exactly reversed. He did not recollect any instance of neurosis in after-life succeeding to child asthma. Nor could he remember any case in which general convulsions occurred during stridulous laryngitis. In laryngismus stridulus the convulsive movements were almost always confined to the limbs.

Suppurative Peritonitis.—Dr. GOODHART read a paper on this subject, of which the following is an abstract. The author related several cases illustrative of the resemblance of the symptoms of suppurative peritonitis to those of intestinal obstruction, in each of which, however, there had been subsequent diarrhœa. A remarkable feature of these cases was the absence of high temperature, and much stress was laid upon the uncertainty of this symptom, as in a considerable proportion of such cases the temperature was not raised at all. The degree and position of pain were also shown to be indefinite in their indications. Diarrhœa, in the presence of other symptoms of peritonitis, must be regarded as a most serious symptom; the bowel in ordinary peritonitis was more or less paralysed, and constipation resulted as a very general rule, but this rule did not hold good for the suppurative form of the disease. The fact that peritonitis, and especially suppurative peritonitis, frequently spread to the pleura by direct extension was insisted upon, and the necessity for closer observation of this point was maintained, apart from the ordinary treatment of peritonitis by opium, belladonna, and the administration of food by nutrient enemata or suppositories. No positive rules of treatment could be laid down. Surgical interference in some cases might save life, but its use could only be determined by close study of the particulars of each individual case; the cases, however, most generally suitable for such interference are those in which the disease shows a tendency to localise itself, or, at any rate, has given some indication of having originated in an accessible situation.—Dr. WALTER PEARSE mentioned a case in which, after resection of the knee, excessive vomiting with diarrhœa, but no rise of temperature, had supervened with fatal result. Suppurative peritonitis had been diagnosed, but none was discovered after death. Enormous dilatation of the stomach was the only abnormal condition.

Cancer and its Treatment.—Dr. BLENKINSOP made a passing reference to the pathology and causation of cancer, and then dealt with the purely medical aspect of the question, both in regard to internal forms of the disease and its general constitutional treatment. He leaned to the belief of a cancerous diathesis, and argued in favour of preventive measures in suspected constitutions. He thought that effort should be made to test the value of all remedies which presented a reasonable prospect of success, and related details of four cases in which lime salts appeared to have had a beneficial effect. He assumed that the deposit of lime salts in the vessels gave rise to atheromatous and calcareous degeneration, and so lessened the supply of blood to the cancerous tissues. Cretaceous preparations derived from the animal kingdom—e.g., from oyster-shells—appeared to derange the stomach less, and to be more readily absorbed.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Jan. 12th, Dr. J. B. Potter, President, in the chair.

Dr. AMAND ROUTH showed a Uterus, with what appeared to be a fibro-myoma attached to the left cornu of a "uterus bicornuate." Early in 1885 there was a history of extra-uterine fœtation.—Dr. W. GRIFFITH and Mr. DORAN remarked on the case, and the specimen was referred to a committee for report.

Midwifery among the Burmese.—Dr. T. F. PEDLEY of Rangoon read a paper which described the occupation, dress, and physique of Burman women. The knowledge of the native doctors is handed down by tradition, and takes origin from fable, horology, astrology, &c, and dieting is followed according to a certain letter, date, name, good or evil spirit. The midwives are of the poorest and lowest class, their chief qualification being ago and being the mothers of large families. The more decrepit, the more they are respected. All new methods are resisted. Nature is kind as a rule to the mother, and carries her safely through. In lower Burmah there is little real poverty, and the women lay by for the event from 5 to 50 rupees. A large store of firewood is laid in. If she cannot buy it, she collects it before her delivery. A room is set apart, where the mother remains till convalescent. Regardless of all sanitary laws, every effort is made to keep out air, and especially the smell of cooking, which is supposed to be particularly injurious. A fire is made of wood, no chimney being provided, and the smoke renders the air stifling. The patient, when in labour, is surrounded by female friends, and a crowd of men and women squat behind the curtain which divides the apartment, and smoke or chew betel. When the pains become severe the patient squats on the floor, supported by a woman sitting behind her. The midwife assists in front by pushing with her hands on the abdomen, using more and more violence as the pains increase. A silk scarf or cloth is tied tightly round the body above the umbilicus, which is drawn tighter as the case proceeds, not with any idea of restraining hæmorrhage or supporting the uterus, but to prevent its rising into the chest. As the head progresses the woman is laid on her back on the floor with her knees drawn up. Her attendants press on the abdomen with all their might. When the head of the child presses on the perineum the midwife leaves the pushing to others, and in all first cases tears the perineum, either with her thumb-nail, which is grown sharp and long for the purpose, or with her great toe-nail. In other cases the perineum is retracted, and, as soon as the head is born, the child is rapidly extracted. If the placenta does not follow quickly the cord is dragged on, and this failing, it is removed by the hand or torn away piece by piece. The mother is washed, and the whole body rubbed with turmeric, and saffron is plastered over the vulva. The fire is kept up, and hot bricks wrapped in rags, or bags of hot sand, are placed on the abdomen, and twice a day the patient has to squat over smouldering embers upon which tumeric has been thrown, or over steam arising from hot bricks. The skin is often blistered by the application of heat, but heat is supposed to permeate the parts and heal them. The food is hot water, hot broth, with fish and rice. The poor get upon the fourth or fifth day, but the better classes scarcely move for a fortnight, except for the daily steaming process and the calls of nature. On the seventh day a hot "pack" is used for some hours, which produces free perspiration. When the blankets are removed the patient is bathed freely in cold water. The constant sweating during the first week brings out a miliary rash, which is considered a good sign. Shampooing or massage is used for hours together, often so excessive over the abdomen that displacements of the uterus are produced. Though Burman women are clean when in health, washing is avoided during sickness, and their habits are dirty. When delivery is not rapid, various barbarous methods are followed, such as standing on the patient's abdomen and pressing or kneading it with the feet, or a bamboo or plank is placed across the abdomen, while the attendants endeavour to expel the child by using all their force at the two ends. This method is very usually fatal to mother and child, and often causes rupture of the liver or bladder. Cases of tetanus often follow lacerations of the perineum, cervix, or rectum; one case of recovery was recorded under the use of chloral. In cross births the part presented is torn or cut off, and the child removed piece by piece, the head being extracted by means of a large fish-hook. In all cases the object is to remove the child as quickly as possible and regardless of risk to the mother, owing to the superstition that if a woman dies undelivered the spirit of the mother and child haunt and bring misfortune to the relatives ever after. Burman women really need little assistance if nature is left to herself. Their pelves are roomy and expulsive efforts strong. The native system leaves little for perverted ingenuity to devise towards preventing recovery, and is about the most severe and fatal in the world. The only remedy is a supply of properly trained Burmese midwives, which the Burman branch of the "Countess of Dufferin's Fund" has determined to undertake. The paper was illustrated with coloured drawings by native artists of the most characteristic points mentioned.—Dr. BOXALL mentioned many points of similarity between the Burmese and Chinese as regards sophistry and superstition in the practice of all the branches of medicine, and the description of the practice of Dr. Hua during the Han Dynasty about a thousand years ago taken from the "Story of the three States" puts modern abdominal surgery back several hundreds of years.—Mr. DORAN asked Dr. Boxall if he knew whether women in the East suffered from disorders incidental to menstruation and pregnancy in consequence of the habit of

Digitized by Google

tobacco-smoking, to which it is said they are addicted from an early age?—Dr. BOXALL was not aware of any.—Dr. W. GRIFFITH thought the paper of great interest as a record of most barbarous midwifery in the nineteenth century, which would be still more interesting at some future time. There was a field open for gentlemen who had the opportunity of studying midwifery amongst various races to investigate the modifications of the process due to different conditions present which are peculiar and normal to these races. Sir W. Turner and others are investigating their crania and pelvis, and have shown such differences in them as to indicate the probability that the mechanism of labour, including the position of the head at the brim, must be altered accordingly.

On Stricture of the Female Urethra, by Dr. HERMAN.—The author had measured the female urethra in fifty-five cases in which no urinary trouble was complained of. He found that in the majority No. 17 catheter would pass, and in all but two No. 14. He related six cases of stricture of the female urethra under his own care. He had collected and arranged in tabular form twenty-three others, which were all that he had been able to find reported. He drew a parallel between the two sexes as to the etiology of urethral stricture, and showed that while it was much commoner in males, its causes were much the same in the two sexes. In both it might be the result of injury (these cases being proportionately commoner in females on account of child-bearing), or of the cicatrisation of chancres. In the female it was sometimes due to growths of so-called lupus of the vulva. In both sexes the chief cause in young and middle-aged subjects was gonorrhœa. In the aged of the male sex enlargement of the prostate was the common form of stricture. In old women there was found stricture due to general fibrous thickening and induration of the urethra, occurring without any history of gonorrhœa or other discoverable local cause. The author suggested that, as in women the homologue of the prostate gland was the urethro-vaginal cellular tissue, these cases were possibly analogous to enlarged prostate in the male. As to treatment, he found that rapid dilatation was so simple and successful that it was preferable to any other method.—Dr. HORROCKS related two cases under his own care, both of which he considered were congenital. He approved of the treatment by dilatation.—Dr. AUST LAWRENCE (Clifton) considered stricture of the female urethra rare. He had only met with two cases in the last fifteen years. One was in an old woman, and appeared to be due to cicatricial bands; the other was in a young woman, probably the result of specific urethritis. Both were cured by dilatation.—Dr. AMAND ROUTH mentioned a case of inflammatory urethritis which appeared to have commenced with anterior parametritis and spread downwards along the cellular tissues of the vagina, a double urethral stricture eventually resulting.—Dr. W. GRIFFITH had that day seen a case at the Samaritan Hospital in a married multipara aged thirty. She had probably suffered from gonorrhœa. The stricture was an inch and a quarter from the meatus, and only just admitted a uterine probe. It was dilated in a few minutes with bougies to No. 13.—Dr. GALABIN related a case, and Dr. HERMAN replied.

ACADEMY OF MEDICINE IN IRELAND.

Parasitic Disease of Lungs of Sheep.—Stricture of the Œsophagus.—Adenoma from the Mammary Gland of a Rat.—Simultaneous Fracture of both Clavicles.—Cerebral Meningitis and Abscess.

A MEETING of the Pathological Section was held on Dec. 3rd, 1886.

Dr. HENRY BEWLEY said that in the lungs of several sheep which were examined lately in the Physiological Laboratory of Trinity College, Dublin, a number of whitish or greyish nodules were found scattered through them, varying in size from $\frac{1}{16}$ in. to $\frac{1}{4}$ in. in diameter. On microscopic examination these nodules proved to be caused by a small nematode worm, from 15 mm. to 17 mm. long, and extremely slender. The worm lay coiled up in the interior of a mass of apparently dried purulent matter. This mass was surrounded by a zone of elongated epithelioid cells, arranged in a radiating manner round the central mass. The epithelioid cells were embedded in a delicate fibrous reticulum; and here and there large giant cells were seen. Around these radiating cells was a zone of small lymphoid cells, embedded in fibrous tissue, and arranged in concentric layers. Outside these cells, in some of the specimens, was healthy lung tissue. In others the nodules were surrounded by catarrhal pneumonia. The worms in these nodules have no reproductive organs, and are apparently immature forms of strongylus filaria—a nematode worm that inhabits the bronchi and trachea of sheep and goats. Leuckart ("Die menschlichen Parasiten," 1867, Bd. ii., p. 107) and Baillet, in a Dictionary of Veterinary Medicine, mention the existence of nodules in the lungs of sheep similar to those in the cases described above, caused by the embryos of strongylus filaria; but they give no account of the histological changes in the lung produced by these parasites.—Dr. MACSWINEY asked if Dr. Bewley looked for this parasite in any other part of the tissue of the sheep. It would be interesting to know whether its habitat was confined to the pulmonary organs, or the parasite was ubiquitous.—Dr. BEWLEY, in reply, said he did not examine any other part of the sheep's body for parasites. He would have liked to examine its trachea, and he hoped to be able to do so at some future time.

Mr. EDGAR FLINN exhibited the Œsophagus and Stomach of a man who died in St. Michael's Hospital, Kingstown, from stricture of the œsophagus, due to malignant disease. The history of the stricture dated back four years, the act of deglutition becoming more and more difficult during the last three months of the patient's life. The stricture became very much contracted during the last three weeks of his existence—so much so that he became unable even to swallow fluid, and had to be fed by nutrient enemata. A post-mortem examination was made, and it was found that the left lung was very much atrophied and collapsed. The walls of the œsophagus were greatly thickened and surrounded by a hardened mass matted together, which implicated the neighbouring structures. The œsophagus was very much narrowed at its lower fourth, and the most contracted part of the stricture was found to be about three-quarters of an inch from the cardiac orifice of the stomach, and would hardly admit of a small-sized penhandle being passed through it. The stomach was enormously dilated, so much so that when the abdomen was opened it appeared to fill up the entire cavity, and was full of a brownish fluid, very offensive in odour. A large fruit-stone was found immediately contiguous, and somewhat beneath the pyloric orifice, embedded in a diverticulum. This fruit-stone must have lain in this diverticulum for a long time, the post-mortem appearances showing that its passage through the œsophagus would have been well-nigh impossible during the last two years of the patient's life; from its position near the pylorus, it exercised a considerable deal of pressure on the pyloric orifice, and thus, in great measure, the great dilatation of the stomach was to be accounted for. The liver was likewise very much enlarged. Dr. M'Kee, the curator of the Royal College of Surgeons in Ireland, had made a microscopic examination of the parts, and had reported that the disease implicating the œsophagus was epithelioma.—Mr. DOYLE asked if the patient showed any symptoms of old pleuritis.—Dr. BALL said one of the most interesting features in the case was the presence of the diverticulum in the pylorus. True diverticula were exceedingly rare. Mr. Moore, one or two years ago, brought before the Pathological Society of London a case of several true diverticula in the neighbourhood of the pylorus; and he suggested that they might be analogues of the multiple diverticula which were present in fishes.—Dr. PURSER said the most interesting point in the case was the dilatation of the stomach. In stricture of the œsophagus the stomach was usually contracted. There must have been some disease in this patient long before the carcinoma of the œsophagus, which produced the dilatation of the stomach. It appeared to him that the pylorus was extraordinarily small. The stricture of the pylorus must have been either produced by disease or congenital. The pouch in the stomach was, he thought, not an abnormality, but the product of the fruit-stone in its ineffectual efforts to get through the narrow pylorus.—Mr. FLINN, in reply, said he was not aware that the patient had had pleuritis or any affection of the chest at a previous date. He did not think there were any diverticula except the one where the fruit-stone was.

Mr. J. A. SCOTT exhibited a specimen of Adenoma from the Mammary Gland of a Rat. At the Carmichael College of Medicine a number of rats were kept. The animals were in the habit of gnawing through their cages and escaping.

Digitized by Google

and others had to be got in their places; and the result was that from 100 to 200 rats had passed through their hands during the last two or three years. The rat from which the specimen was taken was brought to him by the porter. It had a big tumour in its abdomen, into which its legs seemed to be drawn up, very much in the way in which a penis sometimes was into a large hydrocele. Nevertheless, the animal had been several times pregnant, and was able to suckle its young. The rat was killed, and on opening it he found the large tumour that was before them. A section of the tumour showed it to be an ordinary adenoma. A part of the specimen showed the ordinary excretory mammary gland, with a quantity of fat; in other parts there was the gland tissue, and elsewhere a large quantity of fibrous tissue. Dr. Scott said he had invariably opened the dead rats, particularly the females, in order to secure the embryos, but he had never before met with a tumour of the mammary gland in any of them. He did meet with an ovarian tumour, and he hoped to bring it before the Section.

Dr. E. H. BENNETT submitted a cast exhibiting Simultaneous Fracture of both Clavicles, taken from a man who was treated in Sir P. Dun's Hospital, and also the clavicles of a little girl, aged six, who had sustained a complete fracture of one clavicle, and an incomplete fracture of the opposite, by being run over by a tram-car. Having detailed the history and mechanism of the injuries, Dr. Bennett directed attention to the fact that in the first case perfect union had been obtained in both fractures, with but little deformity—a fact of importance, seeing that out of eighteen cases collected by Gurlt, no less than eight had resulted in non-union of the fractures, which was clearly attributable to the difficulty of maintaining the parts at rest in such an injury without the most careful nursing. Dr. Bennett exhibited at the same time a series of injuries of the costal cartilages taken from the body of the child who had had the collar-bone broken. On the right side, the second, third, and fourth cartilages were broken transversely, while the first was dislocated from its rib. On the opposite side one of the lower cartilages had also been dislocated from its rib, and one had sustained a partial fracture. Dr. Bennett directed particular attention to the dislocation of the cartilages from the ribs, as the occurrence of such dislocation had been denied by Malgaigne. He also directed special attention to the incomplete fracture of one of the cartilages, not on account of any great practical importance attaching to the injury, but as serving to complete the analogy between these injuries and fractures of bone.—Dr. MACSWINEY asked, Did Malgaigne, in his criticism, or rather dogmatic statement, that dislocation of the cartilage never occurred, refer to adults or children?—Mr. FLINN mentioned that about eight years ago a case came under his notice of a coal-miner in Staffordshire. While engaged in a lying position in what was called "holing," a very large piece of coal fell upon him and fractured both his clavicles—the one at the sternal end and the other at the acromial end. The lower third of his femur was also fractured.—Dr. MACSWINEY: Did the fractures of the clavicle unite?—Mr. FLINN: Yes.—Dr. BENNETT, in reply, said that Malgaigne gave four cases of this fracture at the age of seventeen, which was the earliest age that he recorded. It was an eminently difficult thing to keep it reduced, for, although after the individual had made a full breath the parts would slip into their places, when the chest collapsed they would slip out again.

Dr. QUINLAN exhibited a case of Cerebral Meningitis and Abscess. He said it was taken from the body of a scrofulous, starved-looking young man, aged twenty-three, who was admitted into St. Vincent's Hospital on Nov. 23rd. He had for many months had an offensive purulent discharge from his right ear, and was on admission suffering from the most agonising pain, radiating from the ear to the frontal, parietal, and occipital regions. His pulse and temperature were above normal, but he was quite clear in his mind, and had no convulsions or muscular stiffness. On the morning of Nov. 25th, about 8.30 A.M., he became suddenly stupid and heavy, and the right pupil became dilated and insensible to light, the left pupil remaining normal. He gradually got comatose, and died at 2 P.M. A post-mortem examination was made twenty hours after death by Mr. Coen, the house-surgeon. The dura mater was firmly attached to the upper part of the brain, the general surface of which was rather congested. On removing the brain, a dark discolouration was perceived on the side of the right middle lobe, and on the back part of the cerebellum and on the medulla oblongata a large patch of recent meningitis with sub[illegible]noid effusion. On opening the right ventricle, it was found full of sero-purulent fluid; and on making a section of the right middle lobe, a large abscess, full of offensive pus, was discovered, corresponding to the dark spot already mentioned. The petrous portion of the temporal bone was extensively diseased; and the cause of the sudden coma on the day of death was, no doubt, the bursting of the cerebral abscess into the right ventricle.—Dr. MACSWINEY said the pathological symptoms in the case were those of chronic purulent inflammation of the middle ear. He wished to ask, What was the condition of the temporal bone and the bones of the ear on the side affected? Was the disease obviously extended from inflammation of the middle ear?—The PRESIDENT: Was an examination made of the petrous bone?—Dr. QUINLAN, in reply, said there was an opening into the petrous bone, from which matter was flowing. He probed it and found the bone quite diseased and disorganised, but he did not cut the bone out. There was the same smell from the pus that came out of the ear as from the pus that came out of the abscess.

Reviews and Notices of Books.

The Life of Sir Robert Christison, Bart., M.D., D.C.L. Oxon., LL.D. Edin., Professor of Materia Medica in the University of Edinburgh, Physician to the Queen in Scotland. Edited by his Sons. In two volumes. Vol. II.: Memoirs. Edinburgh and London: William Blackwood and Sons. 1886.

IN the first volume, already noticed, of this remarkable book Sir Robert Christison is allowed to tell the story of his own life. In the second, which is now before us, the story is largely told by others, though free insertion is given to Sir Robert's own letters. There is, of course, some overlapping and some repetition of subjects; but when the length of Sir Robert's life is considered, and the fruitfulness of it in work and honour and influence and example, this is not only forgiven, but becomes a cause of gratitude to the editors. Chapters 7 and 8 in this volume deserve very special notice. The first is written by Professor Gairdner, and treats of Christison as a physician; the second gives an account of his other scientific work. Christison followed Bright powerfully in his researches in renal disease before the true significance of Bright's discoveries were generally accepted, and he gained from Rayer, the greatest of continental authorities, high praise. His accounts of Fevers and Inflammations will remain very valuable parts of medical literature for their vigour and accuracy. True, he did not accept the modern doctrines of fever, and he persisted in believing that inflammation fifty years ago was of a different type and required a different treatment from that of later years. This is only an interesting proof of the fact that there is a conservative element in the most intelligent minds. And who does not know that Sir Robert was a Conservative?—broad enough to vote for his friend Sir Lyon Playfair so long as he thought him a representative of science and learning rather than of mere political *shibboleths*, but capable at eighty of making a political speech of an hour's length against his friend when he thought he had exchanged the academic mind for the political one. But, his conservative views notwithstanding, his account of the fevers which he saw and the six or seven fevers which he passed through—of which most interesting notes are to be found in this volume, one describing eloquently a personal experience of hyperpyrexia (temperature 107°)—are of permanent interest. Professor Fraser's account of what Christison did in dietetics, toxicology, and materia medica, and still more of what was in his mind to do in the matter of therapeutics by studying first the action of medicines in the healthy body, shows that Christison was on the true scent of the recent great advances in the medical art. His investigations into the action of oxalic acid, of Calabar bean, and of digitaline were original.

Digitized by Google

Christison's knowledge of poisons and his sound common sense made his evidence in all the chief medico-legal cases of his time indispensable. As with Sir Benjamin Brodie in England, the Government sought his opinion on all subjects of medical interest—not only those affecting Scotland and the Scottish Universities, but having wider relations, such as that of vivisection. Of all such subjects, and a hundred more, this volume contains notices that are extremely readable and instructive. For what the volume shows is the many-sidedness and manliness of this Professor, who ruled the University of Edinburgh probably more than any other man for more than half a century, who was absolutely without cant, whom many thought cold and haughty, and yet who was so loved as to be nursed in one of his illnesses, at the age of eighty, by four old pupils, and who was followed to his grave by all that was worthy and reputable in Edinburgh. If the fame he achieved has no charm for some of our readers, perhaps the feats he performed—his rapid ascent of mountains, his walking tours, his captaincy of the Volunteers when over sixty, and his indomitable pluck and hopefulness under illness—may secure their admiration. The study of these volumes, however, cannot but leave the impression of a true leader of men.

Handbook of Diseases of the Ear. By URBAN PRITCHARD, M.D. Edin., F.R.C.S. Eng., Professor of Aural Surgery at King's College, London, Aural Surgeon to King's College Hospital, Senior Surgeon to the Royal Ear Hospital, London: H. K. Lewis. 1886.

THIS manual of Diseases of the Ear, intended "for the use of students and practitioners," commences with a description of the anatomy of the three divisions of the ear, that of the inner ear being especially good. The account of the examination of the ear and the diseases to which it is liable, is given in a short and methodical manner, and, for the most part, is in accordance with what may be found in other text-books on the subject. Some points, however, call for remark.

In making mention of the force-pump (which we believed is now seldom if ever used) as a means of inflation of the middle ear, Dr. Pritchard says that "it requires to be used with the utmost caution, and although it may in certain cases be applied with advantage, there is some risk in doing so"; but the reader is left in doubt as to the selection of these cases. In speaking of an operation for imperforate meatus in cases when some hearing power is present, he recommends the use of a tube to prevent the surfaces uniting, but he does not say whether by this means he has ever succeeded in establishing a lasting meatus. The removal of foreign bodies is carefully considered, and useful cautions, as well as advice, are given. The author regards multiple and rounded exostoses of the meatus as "the result of gouty, or, in some cases, perhaps rheumatic, irritation of the periosteum"; and he is careful to explain why the removal of any exostosis, except to allow a freer outlet for discharge, is rarely advisable, and should never be undertaken lightly.

It is much to be hoped that in another edition of this manual the author will be more definite in his directions in one or two particulars. For instance, in recommending puncture of the membrana tympani in cases of acute inflammation, he says "the operation ought to be performed, if possible, by a practised hand." Surely if this were not possible it were better left unperformed. Again, when suggesting that in cases where an opening into the mastoid process is required the perforator that was figured in Hinton's article in Holmes' Surgery be used, so that it cannot penetrate further than a quarter of an inch, and that if then, by the help of a dentist's elevator and strong nasal probe, pus is not reached, he continues, "and there [illegible] or no advantage in perforating the inner table of the skull, while there must be considerable danger in attempting to do so, for the bone in this position varies much in thickness, and the lateral sinus may be very close." The words "little or no advantage" so applied appear very inadequately to express the results to be expected if the inner table of the skull were perforated. Dr. Pritchard thinks the late Dr. Harvey was correct when he considered that gout and rheumatism affected the middle ear through their action on the joints of the ossicles, and the treatment to be relied upon for this condition is mainly constitutional. The illustrations are well executed and there is a very complete index.

Lehrbuch der Vergleichenden Anatomie der Wirbelthiere. Bearbeitet von Prof. Dr. ROBERT WIEDERSHEIM. Zweite Auflage. Jena: Verlag von Gustav Fischer. 1886.

No better evidence of the excellence of this handbook can be adduced than the fact that the first edition has been rapidly exhausted and that a second edition has been called for. Considerable additions have been made to the old material, especially in regard to palæontological discoveries, the development and morphology of the mammalian skull and of the hard parts of the extremities, the brain and the cerebral nerves, the suprarenal bodies, the cutaneous sense organs, and the thymus and thyroid bodies; and the introductory sections on the development of the urino-genital apparatus have been extended. The account of the respiratory apparatus of birds has received large additions, and the author expresses his obligations to his colleague Dr. Sclater (who is recognised as one of the first authorities) for assistance in this section. In passing, we would call the attention of Prof. Wiedersheim to the indifferent way in which the index has been compiled, for, desiring to read that section, we naturally turned to "Vogel," but that word does not occur. Disappointed in this, we turned to "Respirations organe," and found we were referred to "Athmungs organe," when again no reference to those of birds is made. The word we should have looked for is "Luftwege"; but why not save the time of the reader by giving under the head of "Respirations organe" the reference to those of birds at once, without the annoying proceeding of referring to something else? Surely it would have been easier to have put it after "Respirations organe der Vogel" (p. 735) than "v. Athmungs organe." The bibliography, on the other hand, is drawn up in first-rate style, and occupies sixty pages. The page is larger than in the former edition, and the lines are longer, so that, although the volume is not increased in thickness, it contains considerably more matter. A few additional woodcuts have been introduced.

Our Temperaments; their Study and Teaching. A Popular Outline. By ALEXANDER STEWART, F.R.C.S. Edin. London: Crosby Lockwood and Co. 1887.

THE author very justly draws attention to the importance of temperament throughout life, more especially during the educational period and illness, and to the general neglect of the subject, and the frequent misuse of the word. He makes suggestions for classifying the triple and quadruple combinations of temperaments so common in our mixture of races, the extreme complication of which must often invalidate any sweeping judgments passed on first appearances. From his own observations the author has added the possession of a long neck to the other signs of the nervous, formerly the bilious, temperament. Altogether the book is suggestive, and not less so because, owing to the absence of authorities on the subject, it is rather a collection from every quarter of such materials as have any passing relation to the theory than a treatise of final authority. The volume leaves no luxury of type or paper to be desired, and in addition to other illustrations some thirty faces from Lodge's Historical Collection of Portraits are reproduced as an Appendix.

THE LANCET.

LONDON: SATURDAY, JANUARY 22, 1887.

AT the quarterly meeting of the Council of the Royal College of Surgeons, held on the 13th inst., the result of polling the Fellows on the question of extending the franchise to the Members of the College was duly announced. As will have been seen in our last issue, the Fellows have replied in the *negative* to both the questions put before them—viz., (1) whether Members should be allowed to vote for Fellows as members of the Council? and (2) whether Members should be eligible for seats on the Council? An answer other than negative to these questions was hardly to be expected—could, indeed, hardly have been expected even if the qualification of a certain standing at the College, which is insisted on by the Association of Members acting for the body at large as a *sine quâ non*, had been prominently put forward, instead of having been ignored, by the Council when framing the questions. There is, however, much to encourage the Members in the result of the poll, if this be carefully analysed. In the first place, the total number of available Fellows is 987, and not 1140, as recently estimated by a past President of the College—a fact which still further emphasises the impropriety of so small a part of the body corporate having the exclusive management of a scientific College numbering not less than 17,000 Members. Moreover, from the 987 Fellows to whom circulars were posted only 706 answers were received, and of these six gave no decision one way or another; thus the number of Fellows who have voted on this occasion is actually 700. Of the balance, 21 Fellows failed to get their circular, which was accordingly returned to the College through the dead letter office, leaving 260 circulars unanswered. Of these 260 Fellows it may certainly be said that they are *neutral* in their views; it would not be unfair even to claim them as favourable to the views of the Members. Had they been strongly opposed to the proposed changes, they would certainly have voted against them. On this line of argument, if we count the 260 unanswered circulars as favourable, and deduct them from the majority of "noes" to the first question, we convert these "noes" into a solid majority of "ayes"; while the 354 "noes" to the second question would be reduced to 94.

But even as the figures actually stand the majorities of "noes" are decidedly small, and cannot therefore in any sense be considered final or binding. To the first question, as to whether Members shall be allowed to vote, the Fellows have responded in the negative. Allowing these "noes" and "ayes" to equalise themselves as far as they will, we have a majority of only 143 Fellows to deal with. It cannot for a moment be supposed that the constituency of the College, numbering 17,000 educated men, will consider the question settled by such a vote. We cannot but think that under these circumstances the Council of the College of Surgeons should regard themselves as called upon at once to take steps to give effect to the desires of the constituency at large. As regards the second question, whether Members shall be eligible to sit on the Council, there is a larger majority voting "no"—the "noes" to the "ayes" being as three to one. Even this, however, on such a question, is not the overwhelming majority which might have been expected. To ask the Fellows to give up their cherished privilege of alone being eligible to sit on the Council of the College is to test them very severely, and they hesitate to relinquish their present position. It would be most interesting to know something more about the votes. We incline to think that the "noes" will be found chiefly among the older London Fellows, who are either enjoying a seat on the Council or other office at the College, or are looking forward shortly to do so; and among the younger men, recently admitted Fellows, who have little else to rely upon, and would keep themselves, at any cost, as select as possible. Those who regard the Fellowship as an academic distinction, instituted and kept up for the purpose of promoting a high surgical standard among teachers and hospital surgeons, will rely upon something more than mere title, and will seek to distinguish themselves by their attainments, rather than by the mere exercise of a voting franchise which is denied to the majority of their fellow Members.

If we now look at these figures from the standpoint of the "noes," the Council must themselves see how small and unsatisfactory the majorities are. Fellows voting "no" to the first question number only 419—a minority as judged by the number of circulars sent out; Fellows voting "no" to the second question number only 526—that is to say, a majority of 65 as judged by the circulars issued. Finally, the Council must not lose sight of the fact that 260 Fellows have declined to vote at all. Of course we cannot pretend to forecast what will be the action of the Council under these circumstances. They have never before, we believe, appealed to the Fellows at large for assistance in the settlement of an admittedly difficult problem, and we have therefore no precedents to guide us in forming conclusions as to what their action is likely to be at the present juncture. This we may say in all truth, that the Council of a body corporate have rarely had such an admirable opportunity placed in their hands for gracefully putting an end to an unwise and unconstitutional rule by which about sixteen-seventeenths of the entire body are excluded from all participation in its affairs, and for the introduction of a much needed and greatly desired reform, which cannot but consolidate the College, improve the status of its Members, and raise the profession in the esteem of the public.

The Council of the College of Surgeons have, however, consistently opposed all reforms, and will doubtless in this as in other matters only move when some higher authority absolutely compels them to do so. We must refuse to find any sign of concession even in the resolution proposed by Sir SPENCER WELLS, which was only passed by eleven votes to eight, and still requires confirmation at the next Council meeting—viz., "That although the Council are not prepared to give effect to the recommendation contained in the first resolution carried at the meeting of the Fellows and Members held at the College on the 4th of November, 1886, the Council are prepared to act upon the second resolution, so far as to appoint a small committee to confer on the

Digitized by Google

subject of the first resolution with representatives appointed by the Association of Fellows and the Association of Members. The terms of this resolution are peculiar. If the Council are *not* prepared to give the Members the privileges they seek, what purpose will a conference with the two Associations serve? This determination on their part might just as well be conveyed in a letter. The petitions have been so long, so persistently, and so temperately put before the Council, that a conference on the lines laid down in the above resolution seems unnecessary. In the interests of the Members such a conference is even undesirable, for it simply means delay and procrastination. Meanwhile the Members must notice that the Committee of Charters and Bye-laws are "requested to report further as soon as possible in reference to the proposed changes in the Charter and Bye-laws." Members, therefore, should lose no time in making known their grievances. The official analysis of the recent polling of the Fellows should be placed in the hands of an actuary, and its lessons and indications be thoroughly worked out and forwarded to Her Majesty's advisers along with the formal petition now in course of signature. We can only hope that many new signatures have been added during the present year. If the officials of the Association of Members still want others, we would recommend a house-to-house visitation, with a view to expedite matters, and in order that the petition may be presented with the least possible delay.

No practitioner who has had a lengthened experience in any department of the medical profession can question the existence of a class of *difficult patients*. We do not speak of difficult cases, nor are we alluding to difficulty of the sort which arises out of the necessity of adapting drugs and methods of treatment to the idiosyncrasies of constitution and susceptibility. The perplexities caused by this particular need are often more than sufficiently embarrassing; but it is not of these we are now thinking. Changes which are made gradually, whether in the organism or in the habits of life, do not commonly challenge attention, but are not the less, on that account, effective in their consequences. We are apt to forget that a really great change has come over the spirit of the popular dream of the physician and surgeon and their respective arts during the century which is now hastening towards its close; and one of the most notable and potential features of this change has been the complete breaking down of the fence of mystery which once surrounded the practice of medicine, and which, however intangible and groundless in itself, did most certainly confer this mutual advantage on doctor and patient, that while the former gave his advice with an authority, perhaps fictitious or exaggerated, which has now disappeared, the latter rendered more or less unquestioning obedience, and reaped his reward by having both mind and body brought under the sway of the physician who essayed to relieve him. A great deal of very short-sighted nonsense is spoken and written by well-meaning but narrow-minded people on the subject of mental influence. In the realistic honesty of this enlightened age, it is too commonly held to be a measure of truthfulness that the effects of treatment shall be counted only in proportion as they are physically apparent. In a word, things must be material, either as chemical or directly realistic, in some immediately appreciable manner and degree. All else is disregarded or declared to be worthless and useless, because "imaginary." It is forgotten that the brain is not only the organ of the mind, but in a very potent way the centre of the nervous system, and consequently what may be *imaginary* in its inception may so react on the nervous system as to be fully as real as any other agent in producing material changes and effects, productive of good or evil results, as regards first, the function, and, second, the structure of the organism. Physiology compels us to give weight to what may be termed dynamic, as well as to directly chemical powers and processes. Moreover, it teaches us that the one class of phenomena are as real as the other. It is a strangely perverse "materialism" that seeks to exclude the large class of mental, or, in other words, cerebral, influences from the category of forces operating within the area of the organic life. The bearing of this general proposition on the subject immediately before us may be briefly stated thus: It is not less *unscientific* than it is practically inexpedient to treat patients as though they were simply apparatus for the carrying out of chemico-physical processes. It is not with masses of solid and fluid materials we have to deal, but with living beings like ourselves, with moods and tempers, and susceptibilities and caprices, mental as well as bodily, every one of which must count for something in the totality of disease. It is not with bodily maladies only, but also with mental states, we are required to cope in the endeavour to arrest, or limit, or remedy the effects of morbid action.

The most troublesome class of difficult patients is, we are convinced, composed of individuals who are not treated, as it were, personally. The exigencies of a professional life compel the majority of busy practitioners to form a habit of work which does not readily admit of their bestowing sufficient attention on the question of mental idiosyncrasy. The condition rather than the men are to blame for this defect, but it is a fault of clinical method, and we believe a very serious one. Thus there are difficult patients who would cease to be difficult if it were only perceived that their mental, and collaterally their nervous, conformation and habit of life, require that the processes which are to be wrought out in their organisms in the medication of disease, shall be brought directly under the domain of the consciousness. To take a familiar example of this; cases are not uncommonly met with in which a moderate dose of sedative will not produce quietness, still less induce sleep, or even exert a soothing influence on the nervous system, unless the effect which it is desired to cause by the drug is explained. It is easy to turn this into a jest, and to recall that hackneyed story of the bread pill; but such a line of remark is notable only for its stupidity and ignorance. The true explanation of the effect produced is not that "imagination" puts the patient to sleep, but that the fretful state of unrest which prevents natural sleep is quieted by the perfectly physiological process of removing a source of worry about expected wakefulness, and substituting for it an expectancy of sleep. Even if it were that much-abused agent "imagination" which sent the patient to sleep, without any or with only a minimum of some stupefying poison such as bromide or chloral, it would be

Digitized by Google

better to get the result by simply removing the mental or cerebral obstacles to repose, than by setting up a state of drug-induced stupor. The explanation given to the patient is as much part of the physical process of medication as the administration of an opiate. We merely mention this matter as illustrative of the principle. Precisely the same mental method applies to the relaxation of muscular spasm in the case of a dislocated joint or a troublesome case of fracture, and to the induction of vermicular movement of the intestines in a stubborn case of constipation, and in many other forms of disease. There are patients whose consciousness must be made party, so to say, to the treatment. On the other hand, there are patients who cannot possibly be thus treated, and who must be helped on the way back to health by authority and mystery. To explain processes to patients of this last-mentioned class is to jeopardise success in every respect. In short, the confidence and co-operation of the patient should be secured as aids to cure; and these can only be enlisted on the side of the practitioner by a skilful management of the patient not less than of the disease.

The point on which we are anxious to insist is that *patients* ought to be studied not less than *diseases*, and that, to ensure the largest measure of success in his work, the physician or surgeon needs to be not only versed in the lore of the schools, but to be a man of the world and a close student of men and manners. The class of difficult patients might be more correctly described as a class of persons whom it may be difficult to understand. Difficulty in managing cases generally means difficulty in dealing on the best terms with the individuals who form the subjects of disease. Practitioners too commonly form *habits* of manner and method. We venture to suggest that the medical adviser should approach each patient with an entirely open mind, and study the person as closely and promptly as he studies the disease. The treatment should be adapted equally to the patient and to the disease. Plans of treatment, even particular drugs, may be contra-indicated or rendered specially desirable by the idiosyncrasies of a patient. Difficult patients are nearly always simply misunderstood.

THE occurrence of small-pox on board the North German Lloyd steamer *Preussen*, and the resulting importation of the disease into several of the Australasian provinces, is a matter of grave importance, and it gives interest to the attitude of the Australian Governments towards this disease. The possibility of serious results ensuing from such importation was evidently one of the grounds which led to the assembling at Sydney in New South Wales of the Australasian Sanitary Conference of 1884, when it was unanimously held to be necessary to endeavour to cope with small-pox introductions by means of quarantine; the several adjoining territories which go to make up the mainland and the adjacent islands to be regarded as one state for this purpose, with one Federal Quarantine Act to control the importation of infectious diseases.

The report of that Conference deals in the most candid manner with the quarantine question. It admits that such measure must deal with individuals in an opposite way to that in which the criminal law affects them—that is to say, every person, however free from infection, must be assumed capable of spreading disease until his incapacity to do so has been proved, the period of proof extending at least as long as the period of incubation of the disease. At the same time it is frankly admitted that there is a limit to the period for which a quarantine system will be possible, and it is stated that as the Australasian commerce increases, the possibility of continuing the system will become less and less, and hence that internal sanitation must be proceeded with, because it is such sanitation that is, after all, the true defence of all nations against disease, and the real guarantee of national prosperity. The application of the system as heretofore in force is admittedly accompanied by great hardships. Nothing worthy of the name of quarantine could be done until the terminal port was reached, and then, even if all sickness had ceased on board for even as long as a fortnight, all the passengers and crew were supposed to spend three weeks in seclusion in the quarantine ground, besides restrictions as to the vessel, the cargo, and the process of unlading. These processes, apart from loss to individual passengers, may be estimated in the case of a steam-vessel to cost from £120 to £300 per diem. Without relaxing the stringency of the process, in so far as detention is necessary to prevent importation of small-pox, it was proposed that two quarantine stations should be established, one at King George's Sound for vessels approaching Australasia from the westward, and another at Lizard Point for those coming from the north. The sick and their immediate attendants would be disembarked at once, and, if need be, all passengers would be landed so as to ensure proper disinfection of the vessel. It is also stated that "those persons most likely" to be incubating the disease would also be detained at the first quarantine ground touched at; but what this means it is difficult to say. Indeed, herein lies the main weakness of the system, for although, after the elimination of these sick and suspected ones, whoever the latter may be, the vessel would resume her journey, and the length of that journey would be deducted from the total quarantine detention which would otherwise have become necessary at the port of arrival, yet success would, we imagine, be almost entirely dependent on the complete elimination of persons "apparently well" but who nevertheless had already contracted the infection.

In many cases the process would be facilitated by the vaccination or revaccination, whichever it may be, of all persons on board. Indeed, for all practical purposes a compulsory system of vaccination would be brought to bear upon the passengers and crew. Thus, one of the conclusions of the Conference is to the effect that all persons arriving in an infected ship, and not being themselves affected, "shall be revaccinated," unless they can afford proof of having recently undergone the operation. If the vaccination succeeds, a fifteen days' detention at the quarantine grounds will be required, or its equivalent on board ship; but if any persons refuse to be vaccinated, then the health officer is to have the wide power of detaining them until "he is satisfied of their inability to spread small-pox," and in no case is the detention to be of less duration than twenty-one days. To what extent such a measure could succeed it is impossible to foretell. Its justification appears to lie in the belief that in Australasia the population are not protected by vaccination

Digitized by Google

When contrasting the system with that obtaining in England, the Conference is under the belief that in this country the performance of vaccination is so efficient that small-pox "very properly is not feared." We wish it were so; but so long as years like 1881 give us 2371 small-pox deaths in London alone, we cannot claim the position which efficient vaccination would afford us. In short, it is not the fact of the existence of a compulsory power to vaccinate every child once in its life, and this as imperfectly as the operator may choose, that leads us to deal with small-pox otherwise than by quarantine; but because, as the Australasian Conference very properly puts it, "quarantine against small-pox is at this date an anachronism." The absence of a system of compulsory vaccination must place Australasia at an immense disadvantage in dealing with small-pox, and hence the Conference demands that vaccination shall be enforced. There, as here, a principal trust must be placed on the enlightenment of the population, and it is possible that only in so far as the quarantine system fails will the Australian people as a whole see the necessity for universal vaccination. How far quarantine protections are likely to postpone adequate national protection by means of vaccination remains to be seen, but the Australian Governments are admittedly in a difficulty with regard to the subject.

In the meantime the *Preussen* affair has led to twenty-two attacks amongst the passengers in quarantine at Melbourne; thirty passengers were landed at Sydney, and, the disease spreading, seventy-one cases resulted; and several attacks are reported at Adelaide. We sincerely trust that the disease will be held in check, and we shall look with interest for a report of the actual proceedings adopted with a view to this, and of the results attained.

THE English language is rich in words descriptive of the operation for the removal of procreative organs, such as to spay, geld, cut, and castrate. One of these words only is, however, applicable to the operation in the female alone. The male appendages have been removed in the young of animals, for economic reasons, from time immemorial, and the operation is then called gelding, castrating, or cutting. They have been removed in the human subject, also, for domestic reasons, and the operation is called "castrating" or "gelding." They have, again, been removed in man for disease, and here also the operation has been called castrating by surgeons at all times—castrating for cancer, sarcoma, &c., as the case may be. Within the last twenty years removal of the uterine appendages has been practised for disease of those organs, for epilepsy, nervous disorders, &c.; and the operation has been called "spaying," Battey's operation, oöphorectomy, removal of the uterine appendages, &c.; but objection has been taken to the word "spaying" in this connexion for more than one reason. It is said that spaying means the removal of the uterine appendages in young animals for economic reasons, and that the removal of these organs for disease is not spaying. If this be the case, it follows that removal of the testicles for disease is not castration, and it must be concluded that all the learned men who have written on surgery have been wrong in their use of the word. In the next place, it is said that a kind of reproach or opprobrium is attached to the word spaying. If this be the case, greater is the reproach attached to castration, for the operation has been practised upon the human subject for the purpose of maiming simply—the making of eunuchs. No analogous use of spaying can be proved. It follows clearly from this that if the present use of the term castration in surgery be correct, it is also correct to designate the operation for removal of the uterine appendages in women as "spaying." These reasons for the use of the word, however, hardly deserve mention but for the objections taken to the word, and mentioned above. The real reasons for the use of the word are two—namely, that it is the only English word for the operation, and that it alone, and no other word or words, conveys to English people the meaning of an operation which has been lately not unfrequently performed. It is true that there are other words by which the operation can be explained to persons conversant with anatomy, physiology, and surgery; but all the women who are subjected to the operation of spaying are not versed in these branches of science, and it is not possible to make the operation intelligible to them, and to place them in a position to give consent or refusal to undergo it, except by the use of the word "spaying." But after this word has been given in explanation, there will remain a certain number of young girls under twenty—for it should be borne in mind that such have been made the subjects of removal of the uterine appendages—who do not understand the meaning of the operation. Under such circumstances—if the operation be necessary—the parents and friends should be made to understand what the operation proposed really is, and we know of no other way of doing this, as a rule, than by the use of the expression "spaying." That a certain reproach is attached to barrenness in women is well known, and this reproach is all the greater when all hope of becoming a mother is destroyed by the removal of the uterine appendages; but the reproach is not in the word, but in the condition secured beyond hope by the operation. We would be the last to use the term "spaying" or "castration" in any way offensively or as a term of reproach, but we advise its use in justice to those who are about to be subjected to the operation, and to their friends.

Annotations.

"Ne quid nimis."

THE ERASMUS WILSON BEQUEST.

A VERY influentially signed memorial (see page 193) has recently been addressed to the President, Vice-Presidents, and Council of the Royal College of Surgeons of England referring to the disposal of the Sir Erasmus Wilson bequest, and directing their special attention to the need of support of certain collateral branches of medicine, "which can only flourish by liberal pecuniary aid." The memorialists suggest to the Council the great desirability of founding an institution under the direction of the College, having for its object "Physiological and Pathological Research." They deplore the absence of any such institution in England, and that English students should have to look to continental schools for the elucidation of such questions, for instance, as tubercle or hydrophobia. They draw attention to the splendid laboratories which exist not only in the other capital cities of Europe, but in comparatively small towns,

Digitized by Google

such as Leipzig or Bonn; and while pointing out that there is little or no prospect of such an institution being founded by the Government, they urge its national importance, and the value of the scientific work and training which could be carried on under the auspices of such a body as the College of Surgeons. This memorial was at the last Council meeting referred to the committee appointed to consider as to the disposal of the Erasmus Wilson legacy. We can only hope that such an evident hiatus in our higher educational establishments will appeal to their judgment and good sense, the more so as the memorial is signed by some of the foremost scientific men of the day. Rumours have been published that extensive pulling-down and rebuilding schemes are contemplated, and that enlargement of existing departments rather than the foundation of new ones finds most favour with those whose voices command the greatest attention at the Council table. Scientific men will await the deliberations of this committee with considerable interest; should they decide to devote some of the funds at their disposal to the above purpose, it is not unreasonable to hope that other funds in process of time may be placed at the disposal of the College to enlarge, amplify, and further endow this kind of work. It is not a little curious that, of all European capitals, London alone should be entirely without a physiological and pathological institution, open to its scientific men, for the elucidation of such questions of public health as those just mentioned, among many others. The Council of the College of Surgeons have now a magnificent opportunity to make good this great want. We sincerely hope that they will not fail to avail themselves of it, and of the occasion it affords of consulting the opinions of the great body of Fellows and Members, whose voice should unquestionably be heard in a matter of such public no less than professional importance.

THE VENTILATION OF CHURCHES.

A PROVINCIAL contemporary relates a serious accident which occurred at Staplegrove Church, near Taunton. About the middle of the service it is said, many of the congregation felt a peculiar faintness, which by the time the sermon was drawing to a close caused several to fall "like ninepins about the church." The lady organist is reported to have fallen on her face in the aisle, while several others followed her example, the rest of the congregation escaping through the doors, faint and overcome. Probably it will be found that the disaster was caused by the accidental introduction of carbonic acid gas from a coke furnace into the interior of the church; but, however this may be, we hope it will lead to a thorough investigation into the ventilation of churches. It is often pleaded, we cannot help feeling unjustly, that other influences than those of ventilation are sometimes the occasion of the drowsiness of congregations. The clergy are therefore perhaps interested in the subject not less than those who attend their churches; but we would beg to remind medical officers of health that their duties include the recommendation of proper ventilation of places where large assemblies are held, and that this is so far recognised by the Legislature that metropolitan medical officers are required by the Metropolis Local Management Act "to point out the most efficient modes for the ventilation of churches, chapels, &c." It would be an instructive piece of work for any health officer to give an account of the various methods of warming and ventilating the churches and chapels in his district, and by comparing one with another to show the reasons of their failure to keep the congregation warm without contributing to the drowsiness which is not infrequent in these buildings. He would undoubtedly find that in many instances no serious attempt is made to warm the church until very shortly before the service commences; the walls are necessarily cold, and thus a higher temperature is required for the air which is admitted to compensate for this disadvantage. The hot air is almost invariably admitted from the floor alone; and as insufficient ventilation is provided in the roof, the hot column of air, which rises as high as possible, presses down until all the colder air beneath is excluded. At this period the congregation are warm, but the air they breathe has become more or less polluted, and the effects of carbonic acid become in corresponding degree evident. The use of flues or shafts for carrying off the heated air would not accord with the notions of ecclesiastical architecture, and thus it cannot be expected that the atmosphere of a church can be exchanged as rapidly as that of a dwelling-room, although proportionately it may contain ten or twenty times the number of occupants. There are probably no badly ventilated churches which could be satisfactorily improved without material alteration in the existing arrangements, but certainly much could be done by thoroughly warming the structure before it is used, instead of leaving it for days together at a temperature which must approximate somewhat closely to that of the outside air.

A CALCULUS IN THE BRONCHUS.

La Enciclopedia publishes an account, by Dr. Don Luis Montané, of a case communicated by him to the Havana Academy of Sciences. The patient was a young lady from the United States, who up to 1884, when she was first seen, had enjoyed good health. In that year she had an attack of pleurisy on the right side, for which parathoracentesis was performed, which removed 930 grammes of fluid. After this she completely recovered. In the early part of 1886 she was again seen for a persistent dry cough, which was considered to be due to pharyngitis, but which did not yield to the remedies prescribed. A painful spot was complained of at the base of the neck a little above the left sterno-clavicular articulation. Up to May 13th there had been no elevation of temperature; for some days after this, however, there was a slight degree of fever, which was quite unaffected by quinine. The cough afterwards became more spasmodic—somewhat resembling whooping-cough; some streaks of blood also appeared in the sputum. On auscultation occasional dry rhonchi were heard over the left apex, and a slight roughness in the breath sounds; there was, moreover, a want of percussion resonance in the left infra-clavicular region. An active counter-irritant was applied, and digitalis ordered, but no good effect was produced. On the morning of May 20th it was noticed that the respiratory sounds over the left apex had become weaker, and in the afternoon the whole of the left lung was almost impermeable to air, only some very slight rhonchi being perceptible at the apex; the percussion resonance was also highly exaggerated, showing the existence of an emphysematous condition of the entire lung. A consultation was now held with Dr. Jover, who suggested that there might be pneumonia of the apex, and that a pseudo-membranous plug, due to the inflammation, was obstructing the left bronchus. He proposed to order an emetic in the hope of dislodging this plug. After ipecacuanha had been given, the cough became less violent, the fever diminished, and the air entered more freely into the obstructed lung. The next morning, however, all the previous symptoms returned with as much severity as before, and this condition continued till May 24th, when the patient, during a violent fit of coughing, expectorated a hard substance, which proved to be a calculus. It measured one centimetre by seven millimetres, and was irregular, ovoid, and hollow, with a rough surface. Its weight was twenty centigrammes. On analysis it was found to be composed of carbonate and phosphate of calcium. Immediately after the expulsion of this body the

Digitized by Google

air penetrated freely into every part of the left lung, the cough disappeared as if by magic, and the fever gradually diminished, till in three days' time the patient was perfectly well. The author states that this is the first case of the kind which has been reported in Cuba. Indeed, such a case as this is of extreme rarity everywhere.

THE LONDON UNIVERSITY.

THE House of Convocation of the University of London met on the 18th inst., the chairman of the body, Mr. Frederic John Wood, LL.D., presiding. After the report of the annual committee had been presented and adopted, a long and animated discussion took place respecting the selection of an appropriate motto for use in connexion with the University arms. Several mottoes and proverbs were submitted, but ultimately it was resolved, on the motion of Sir Albert Kaye Rollit, LL.D., that the whole subject be referred back to the annual committee, with power in conjunction with the Senate to select a motto, and that the members of Convocation be invited to send in appropriate mottoes. Sir Philip Magnus presented the report of the special committee on the constitution of the University. He referred to the conference that had taken place between the committee and the Senate, and the desire of the Senate to meet the wishes of Convocation as to the reconstitution of the University. He noted the scheme proposed by the Association and that of the Royal Colleges of Physicians and Surgeons, and concluded by expressing his conviction that the grievance of the medical schools was a real one, which he hoped the Senate would find some way of removing. The questions of the establishment of a Doctorate either of Literature or Philosophy and the regulation of expenses were referred to the Annual Committee, and the meeting was adjourned.

VACCINATION IN PERU.

IT is satisfactory to learn, from a recent number of *El Monitor Médico* (Lima), that some steps are being taken to persuade the Government of Peru to establish compulsory vaccination in the Republic. At present the only place where the compulsory system is in force is in Lima itself, where it has been established as a local enactment by the municipality. Provincial vaccinators find the greatest difficulty in keeping up supplies of lymph, and are frequently obliged to apply to the Lima authorities, who, at the desire of the Government, assist them as far as possible. The Free Academy of Medicine has recently caused the whole matter to be looked into, and a report to be drawn up by a committee of its members. They say that the frequent epidemics of small-pox and the numerous cases that are constantly occurring in most of the towns of Peru are accountable for a large part of the present high rate of mortality; that the experience of all other countries shows that the only way to make vaccination really effective is to render it universal by compulsion, which cannot be carried out without arrangements for supplying lymph to all requiring it; and that the best way of doing this is to confide the charge of a central establishment to a scientific body—that is to say, to the Academy of Medicine. It is remarked that the neighbouring republic, Chili, established compulsory vaccination in 1884, and has an institute of animal vaccination in Santiago which is subsidised by the Government to the extent of 3500 dollars a year. In the case of Lima, the municipality seems disposed to take the burden of establishing a national animal vaccine institute upon itself. The Academy suggests that all parents should be compelled to have their children vaccinated before they are three months old, and that all persons should be revaccinated every ten years. The authorities of all penal and charitable institutions should be obliged to see to the carrying out of the vaccination law, which of course would be rigidly enforced in the army. It is also suggested that the local boards of health should be authorised to give two prizes annually to the most successful vaccinators in the district. The distribution of lymph and the instructions for vaccinators the Academy would wish to have left in its own hands.

PATHOLOGICAL SOCIETY.

THE crowded benches on Tuesday last testified strongly to the popularity of the movement that caused Sir James Paget to accept the presidential chair of the Pathological Society. The acceptance of this office will prove of great value not only to the Society, but to the cause of pathology at large. It is well known that Sir James Paget is disposed to sympathise with every extension of pathological science likely to conduce to the advancement of this important branch of medicine. We were particularly gratified with that portion of his address pointing out that there need be no inconsistency between practice and science. The scientific mind may place all things in a scientific light. The illustrations from clinical medicine by the new President were full of significance and meaning to those who look below the surface of things. Excellent indeed was the recommendation to examine all morbid tissues whilst they are yet living. That there is no exaggeration in the notion that tissues just removed from the body might be regarded as still vital will be conceded all the more when the facts of skin, tendon, and nerve grafting are borne in mind. The occasion was, indeed, an exceptional one for the Pathological Society. The actual combination of the faculties of the pathologist and the orator is necessarily rare, and the audience of last Tuesday signified their appreciation of the presidential appointment by according to Sir James the warmest possible reception of his address. Sir Joseph Lister proposed the vote of thanks for the "beautiful and instructive" address; and Dr. Samuel Wilks, in seconding the vote, echoed the conviction of everyone in his allusion to the youthful vigour of the President's intellect.

THE ETIOLOGY OF PULMONARY GANGRENE.

DR. BONOME of Turin contributes (*Deutsch. Med. Woch.*, 1886, No. 52) some new facts upon the intimate pathology of gangrene of the lung, a condition which supervenes under most varied circumstances, being sometimes the outcome of acute lobar pneumonia in cachectic subjects, or the result of inhalation of putrid matters, or of the embolic impaction of thrombi from infective centres. The gangrene may be limited and circumscribed, or diffuse and widespread; it may be confined to a single area or disseminated in multiple foci—variations depending largely upon the antecedent condition. Dr. Bonome's investigation refers to circumscribed gangrene, and would apparently include the metastatic pulmonary abscesses of pyæmic infection. He describes the focus as divisible into four zones, which, *mutatis mutandis*, could stand also for those of a pyæmic abscess. Thus in the centre, he says, is a necrotic zone made up of the débris of dead leucocytes and of micro-organisms, to which the necrosis is due, this necrotic change including a fibrinous metamorphosis of the protoplasm of the alveolar epithelium (coagulative necrosis) and destruction of the inter-alveolar septa. Then comes a zone of a granular appearance, composed of broken-up leucocytes, which stain deeply with carmine. Around this is a zone of hæmorrhage, whilst outside all is a zone of catarrhal inflammation. Examination of the necrotic focus in fresh specimens revealed, in addition to putrefactive bacteria, masses of micrococci; and cultures in agar-agar and peptone-gelatine enabled the determination of the variety of micro-organism. This

Digitized by Google

proved to be the staphylococcus pyogenes aureus and albus, and its special necrotising power was proved by inoculation of pure cultures both directly into the lung and indirectly through embolism. In this way pulmonary gangrene can be artificially induced in rabbits, control experiments with other microbes—as the pneumococcus and microsporon septicum—failing to produce the same effect. The staphylococcus is the micro-organism which has been proved to excite infective osteomyelitis, furuncle, paranitium, inflammation of subcutaneous tissue, and ulcerative endocarditis,—so that its action upon lung-tissue is not singular. It may be introduced into the lung either directly through the air-passages or metastatically conveyed by the blood-stream (embolic gangrene). Wounds of the lung by instruments infected by the staphylococcus pyogenes rapidly produce necrosis and inflammation. The putrefactive process is caused by the free entrance of saprophytes by the bronchi; the peculiar odour of gangrenous foci being due to this secondary change induced by contact of the necrotic patch with atmospheric air.

DEATH OF A CADET AT WOOLWICH.

THE recent death of one of the cadets of the Royal Military Academy, Woolwich, from a fall while sliding on an extemporised slide, is the first that has occurred in the hospital since it was attached to the Academy some forty years ago. The case from a medical point of view is instructive, as showing what serious results may follow a blow on the head which at first is thought but little of. In this case the patient was able to walk about and take his meals after his fall, and it was not till the middle of the night that the surgeon was called to him on account of severe pain referred to the zygoma, which was the part struck. He was then removed to the hospital, which is distant two or three hundred yards, and walked there without difficulty. The patient slept and took his breakfast. In a few hours, however, coma came on, preceded by sudden accession of acute agonising pain in the head, death occurring in the afternoon. At the necropsy an immense clot was found between the base of the skull and the dura mater, the blood having come from a small puncture in the middle meningeal artery, caused by a minute spicula of bone which had been detached from the suture between the orbital plate of the frontal and the left wing of the sphenoid.

THE DARENTH HOSPITAL DISPUTE.

THE question whether the hospital at Darenth should be constructed with wood or brick—that is to say, whether it should be temporary or permanent—came again before the Metropolitan Asylums Board at their meeting on Saturday. The occasion for the further consideration of this subject was the receipt of a letter from the Local Government Board agreeing to the proposal of the managers that the material to be used should be brick, but that the managers should modify their former proposals as to the manner in which the institution should be constructed so as materially to reduce the cost. The opposition to a brick building which has been shown by various district authorities is evidently due to the belief that, inasmuch as wood is a less expensive material than brick, it is more economical to use the former. The determination of the managers to persist in their intentions is based upon the fact that in the course of time wooden structures cost more money than those which are of a more permanent nature. The objection of the Local Government Board is founded upon the uncertainty of medical knowledge as to the proper method of construction of small-pox hospitals. It is matter for regret that the Central Board have not freely placed before the managers the whole of the information available with regard to this point; they would undoubtedly have carried the managers with them. But, as we have already pointed out, the use of wood or brick is merely incidental to the real question which underlies the whole—viz., the means which must be taken to prevent the small-pox hospital being a source of danger to the neighbourhood in which it is placed. There is much reason for believing that the aggregation of persons convalescent from small-pox is in its effects very different from that of persons in the acute stage of the disease. But although the Darenth Hospital is intended for convalescents, it may be accepted that it will, in the course of epidemic pressure, eventually receive a much larger number of acute cases than Mr. W. H. Power found to be necessary for the dissemination of the disease. There is no economy in building even a temporary hospital upon principles which do not include a full recognition of this fact; and the authorities who fail to be guided by the experience of past epidemics or to take measures for adding to the knowledge which already exists are incurring a serious responsibility, and will find eventually it will be no easy matter to justify their procedure when the influence of small-pox hospitals is more fully known.

"ON SOUL AND CONSCIENCE!"

THE medical certificate constitutes one very useful safety-valve for educational over-pressure. Were its just influence ignored, the effect on the public health would be far from satisfactory. Were the same influence pushed into abuse or indiscriminately applied, it would certainly come into contempt, with a like result. According to the School Board of St. Cyrus, the medical profession in that parish is not guiltless in this particular; but the remedy suggested at a recent meeting is certainly a novel one. A member proposed with all gravity, as a possible solution of the difficulty, that absentees must be excused on the ground of illness, which would not in future be admitted on the mere assertion of a medical practitioner, but must be certified by him "on soul and conscience." This proposal, it seems, was not intended for burlesque. Whatever it means, it is not likely, we fear, to improve materially the school attendance at St. Cyrus. Probably the most practical means of correcting the truant tendency, if it is really to be so described, would be to issue a form requiring certifying practitioners to state precisely the fact of a personal examination and the nature of the illness for which a certificate is granted. We need hardly again impress on our medical brethren the need of due care in examination, as malingering is by no means unknown among children.

MORPHINE IN DIABETES.

THE good effect in certain cases of diabetes of administering morphia has seldom received better illustration than is afforded by a case recorded by Dr. Mitchell Bruce (*Practitioner*, Jan. 1887). The patient was a printer, aged twenty-six, and was under observation for ten months. During this time a series of observations were made as follows. For two days he was placed on ordinary mixed diet without medicine, and the average daily excretion of sugar was estimated at 1360 grains. In the second place, for about three weeks he was kept on "strict Pavy diet," but without any notable diminution in the amount of sugar excreted. This was followed by a third series of observations, when, with continuance of the rigid diet, acetate of morphine was given by the mouth in increasing doses, commencing with fifteen minims, every four hours. The amount of sugar began to diminish notably. On the fifteenth day, when three grains of acetate of morphine were being ingested daily, the sugar had fallen to 912 grains; on the forty-eighth day (4½ grains of acetate of morphine) to 360 grains; and from the fifty-sixth to the sixty-first days of this treatment (4¾ grains of acetate of morphine) sugar was entirely absent

Digitized by Google

from the urine. It was only towards the end of this series of observations that any narcotic effect, and that inconsiderable, was produced. On discontinuing the drug, but still maintaining the rigid diet, there was a rapid reappearance and daily increase in sugar—viz., from 600 to 2400 grains. Still continuing the diet, observations were now made of the effect of morphine administered hypodermically, with gradual increase from about ¾ grain up to 3 grains per diem. The amount of sugar excreted never fell below 768 grains, whilst the drowsiness of the patient required a reduction in the drug, with an increase in the sugar excreted, until the latter reached 3000 gr. Recourse was now again had to the administration by the mouth, and by the seventeenth day of such administration the sugar had fallen from 4000 to 1000 grains; by the forty-fourth day it reached 882 grains; but it was not until the ninety-ninth day, when seven grains of the acetate were being given daily, that the sugar was reduced to a mere trace. The patient's general condition correspondingly improved. Dr. Bruce, in his concluding remarks, considers that the glycosuria in this case was proved by the foregoing results to be due to an increased income of sugar in the blood, and not to its diminished destruction in the system; for the morphine had less influence on the glycosuria when introduced into the general circulation than into the portal circulation. It also showed that glycogenesis was still active, and that this was going on mainly in the liver; and that, if of nervous origin, the disorder was in the liver itself, and not in the central nervous system. For whilst the hypodermic administration produced marked depression of the central nervous system, the drug given by the mouth had much less effect, operating mainly on the glycosuria.

THE GREAT NORTHERN CENTRAL HOSPITAL.

THE men of the north of London have an object well worth their consideration and sympathy in the Great Northern Central Hospital. This subject divides itself into two parts—the maintenance of patients in the existing hospital in the Caledonian-road, and the provision of funds for building the new hospital in the Holloway-road. We regret to see that on both heads the financial report at the annual meeting (Mr. Marshall Lang in the chair) is unsatisfactory. The maintenance fund is £657 short of last year, and the funds in hand for the new hospital are so small that the promoters have determined to proceed with only one block of buildings, at a cost of £2000. This is highly judicious on the part of the committee, but we trust that in this Jubilee year we shall see them supplied with the £24,500 required to make the new hospital complete and worthy of the populous district by which it is surrounded

HEALTH OF MAURITIUS.

THE annual report of the medical department of Mauritius for the year 1885 is remarkable chiefly for the very small amount of information which it furnishes on the subject of the health of the population. It states that the health of the colony was by no means satisfactory. "Some localities in Mauritius are as healthy as England, and others again are little less than pestiferous." But it does not give a single figure to show what was the death-rate of the island generally, or of any of the districts, with the exception of Rivière du Rempart, in which it amounted only to 21·82 per 1000 of the population. This total absence of detailed information as to the death-rate is the result, apparently, of the returns which were furnished not being printed—an instance of extravagant economy, for without them the report is of scarcely any value. We would suggest to the Chief Medical Officer that in future, instead of merely referring, as in the present report, to tables which may not be printed, he should state in the text of the report the numerical results which are shown by them. As illustrating the very unhealthy condition of the island, and at the same time the prevailing distress, the Chief Medical Officer states that about 44,000 cases of disease were treated in the medical institutions of the colony in 1885, but he does not state the population. Assuming it to be 370,766, as given in Whitaker's Almanack, this would show that one in eight had thus obtained medical relief. The report shows that 15,488 cases were received into the public hospitals, and of these 1366 died, being in the ratio of 88·24 per 1000 treated. This high death-rate was, doubtless, to a considerable extent due to the condition of the patients on admission, for in the Civil Hospital, for which alone the details are given, of 598 deaths 213 took place within forty-eight hours after admission. Malarial fevers, including under that term also cases returned as "malarial cachexia," were the most prevalent and fatal diseases admitted into the public hospitals; there were 5749 cases returned with 240 deaths; of dysentery there were 693 cases and 216 deaths; and of pneumonia and pleurisy there were 264 cases and 156 deaths. Pneumonia appears to be a very fatal disease in the island; at Powder Mills Hospital 21 cases were admitted, and all died—"a fact sufficiently remarkable to deserve explanation," but of which no explanation is given. We cannot but regret that the information repecting the health of the island is so very meagre, but we trust that before the next annual report is due the Chief Medical Officer may be able to satisfy the Governor of the necessity for publishing the usual statistical tables, if the report is to have any practical value.

DENTAL CARIES IN BAKERS.

DR. FR. HESSE has given a detailed description in a recent number of the *Deutsche Monatschrift für Zahnheilkunde* of a peculiar form of caries especially affecting the outer surfaces of the teeth. The caries is soft, rapid in its progress, and penetrates deeply. It commences at the neck where the tooth is in contact with the gum, and extends more towards the free cutting edge than towards the fang. The discolouration produced is of a brownish tint. It commences early, usually attacking patients between the ages of seventeen and twenty-three. He refers it to the inhalation of meal dust, and thinks it also occurs in millers. It most commonly first attacks the upper front teeth, eating away the enamel, the eroded edge of which is sharply defined, and exposing the dentine, which assumes a brownish or even black colour. The same conditions are found in sugar-bakers and in confectioners, both of whom remain long in rooms the air of which is loaded with sugar dust, and who have often to taste hot saccharine substances. Hesse therefore considers this condition to be caries induced by sugar. A similar defect is found in the front teeth of children who are fed with certain kinds of sacoharine farinaceous food, such food being often in a state of acid fermentation.

DIPHTHERIA AT BASSINGBOURN.

A SERIOUS epidemic of diphtheria, which attacked sixty children in thirty-seven families in the adjoining parishes of Bassingbourn and Kneesworth in the Royston rural district, has just been reported on by Dr. Anningson. The epidemic commenced on June 13th last, and continued for fifteen weeks until Sept. 25th, and the peculiar feature attaching to it was its apparent connexion with a polluted water-supply at the elementary school. The incidence of the disease was certainly very marked on the girl's side, where this polluted water was available, but at the same time it is difficult, in the face of the existence of other means of diffusion, such as are in operation in an elementary school, to eliminate all the usual conditions favouring personal com-

Digitized by Google

munication, and to assign the disease to a water-supply. The Bassingbourn outbreak is regarded as having, in the first instance, been brought about by the recrudescence of a previous epidemic, and school assemblage is admitted to have been a main cause of its introduction. Hitherto, although there have been similar cases in which polluted water has appeared to have been associated with the spread of diphtheria, this circumstance has, as a rule, been overshadowed by some more potent factor, such as personal communication during school attendance. The influence of such attendance in causing diphtheria is well known; that of a polluted water-supply is as yet not definitely made out. But all such cases as that under consideration are well worthy of study in this connexion.

METROPOLITAN SEWAGE DISPOSAL.

WE observe with regret that the Metropolitan Board of Works have accepted an estimate to provide, at an enormous cost to the metropolis, the tanks and jetty which are necessary for treating London sewage in the manner upon which the Board had previously decided. We have recently so fully discussed this matter, that we fear it will serve little purpose to reiterate the arguments we adduced against this method; it will be sufficient for most of the ratepayers to know that the Metropolitan Board is acting in defiance of the recommendations of a recent Royal Commission which carefully studied this subject in all its bearings. The Metropolitan Board only indirectly represents those who will have to bear the cost of this unwise undertaking; they represent the vestries and district boards, and upon them must devolve the chief duty of opposing the scheme against which we have felt it necessary to protest. But we observe with much satisfaction that an influential meeting of ratepayers was held on Wednesday to consider the question of London sewage disposal, and that at this meeting a resolution was adopted strongly protesting against the action of the Board. A committee has moreover been appointed, which will, we trust, urge this view upon those who are responsible for the wasteful expenditure contemplated. We are not, however, sanguine of the result. It will be very difficult for the Metropolitan Board at this period to withdraw from a position which has already been taken up, but we gladly see the effort made to induce them to adopt this course, if only to demonstrate that the metropolis as a whole is not wanting in wisdom.

THRIFT IN COOKERY.

ECONOMY in the kitchen has long been recognised as a domestic virtue; and in these days, when cooking has become more than ever a fine art, it is satisfactory to note that old-fashioned household thrift can well keep pace with the advance of custom. Important as this fact is on general grounds, it is no less important in the treatment of the sick. In the various forms of fever, as is now generally admitted, the value of suitable nourishment can hardly be exaggerated. The case is not different in instances where the failing powers of age rather than the nature of disease form the chief obstacle to recovery. Here time gained may be life saved, and a diet at once palatable and digestible therefore becomes a primary consideration. For the wealthy invalid such a diet is not difficult to obtain; the resources of cookery are at his command. The poor in illness are less fortunate, though much may be accomplished in the same direction by the introduction among them of simple but efficient means of cooking, which appear in careful hands to answer many of the purposes of a more elaborate system. Of this we are reminded by the excellent teaching conveyed in a small and practical manual by Miss E. de V. Mathew, entitled "Cookery for our Sick and Invalid Poor." This little work contains a large number of recipes, with hints as to ready methods in cookery, which bear the mark of experimental training. Some of the dishes enumerated seem to us rather too rich for an invalid. This defect, if it prove such in practice, a little judgment might easily remedy. In another pamphlet the same lady treats of "Tinned Meats &c., and how to use them." It is an unfortunate thing that the wholesomeness of food preserved in this way is not yet so far above suspicion as to render all care in its selection unnecessary. This fact does not, however, suffice to forbid the discriminating use of such food, and it does not in any way impair the general excellence of the advice contained in the pamphlet just mentioned. Whilst on this subject, we may direct attention to a device introduced by Mr. H. T. Tallack, of Hatton-garden, in the shape of stout steel skewers, each headed with a hollow iron sphere, and which being thrust deeply into the substance of the joint prepared for roasting, serves to conduct the heat more readily into the centre of the meat, thus ensuring more rapid and complete cooking.

MEDICAL FEES IN CROWN CASES.

WE have often in our columns directed attention to the inadequate fees paid to medical witnesses in Crown cases. In a manslaughter case at Wigan, last week, Dr. Brady, one of the medical witnesses, refused, when before the magistrates, to be bound over to appear at the Liverpool Assizes, alleging as a reason that he would not undertake to leave his patients and practice from day to day to attend the Assize Courts at Liverpool for the remuneration offered by the Crown. He was willing to give evidence and render what assistance he could when called upon, but he would not from day to day wait about the Assize Courts till called upon for £1 1s. per diem. The magistrates on the bench threatened him with all the pains and penalties possible if he refused to be bound over, and the assistant magistrate's clerk stated that, with an experience of thirty-five years, it was the first time he had known a professional witness refuse to be bound over. Dr. Brady assured the clerk it was not too late to begin, and he was eventually allowed to leave the court without being bound over. We agree with Dr. Brady as to the inadequate remuneration, and think it ought to be two or three guineas at least. A medical practitioner's time is usually too valuable, not only to himself, but to his patients, to be wasted in waiting about law courts day after day.

SIMPLE METHOD OF ESTIMATING THE EFFECTS OF RESPIRATION.

MM. HANRIOT and Ch. Richet have described a method of measuring the oxygen inhaled and absorbed, also the carbonic acid formed, during respiration, which is much more simple than the usual method by weighing, and is adapted for carrying out at the bedside. A gas-meter measures the volume of air inhaled, and a second that of the air expired; this air is then passed through potash and subsequently through a third gas-meter. The difference between the second and third meters of course gives the carbonic acid formed, and the difference between the first and third the oxygen absorbed.

POLICE EMERGENCY CASES IN EDINBURGH.

THE Public Health Committee of Edinburgh have had before them the arrangements for securing medical attention for emergency cases. The question of appointing police surgeons in different districts was raised, but was not favourably received. The present system was approved, by which the nearest practitioner is to be summoned by the police, who are to give remuneration according to the time at which the service is required.

THE ELASTIC LIGATURE FOR UTERINE FIBROIDS.

THE removal of uterine fibroids by means of the elastic ligature having been recently adopted by Prof. Slavyanski in four cases, a paper has been published by one of his pupils, Dr. Zhabotinski, dealing mainly with the history of this method of operating. He has collected accounts of 216 cases, of which 151 are British (44 being Dr. Robert Lee's), 27 French, 20 German, 10 Russian, 5 American, and 3 Italian. Of these 18, or 8·3 per cent., proved fatal—8 from peritonitis, 3 from septicæmia, 3 from exhaustion, 1 from pleurisy and peritonitis, 1 from meningitis, 1 from tetanus, and 1 from an accidental disease. In 12 of these death occurred before the tumour came away, and in the remaining 6 after separation had taken place. The author thinks that the opinions of West and M'Clintock on the dangerous character of this method of procedure were formed on the results of too small a number of cases, and that as most of the published cases occurred in pre-antiseptic times the danger with modern methods may be looked upon as very slight. The mode of procedure which Prof. Slavyanski adopted, and which in Dr. Zhabotinski's opinion is the best, is to cut away the tumour after the elastic ligature has been applied to the peduncle. This seems to have given the best results, even before the days of antiseptics. The main indications for the elastic ligature operation are a pedunculated condition of the tumour, an accessible situation, and a disposition to hæmorrhage.

THE GENERAL MEDICAL COUNCIL.

PURSUANT to the provisions of the Medical Act of 1886, the following appointments have been made:—Dr. John Struthers, to represent the University of Aberdeen; Dr. William Leishman, the University of Glasgow; Sir William Turner, M.B., the University of Edinburgh; Dr. William Moore for Ireland; and, as announced last week, Professor Bell Pettigrew, the University of St. Andrews.

THE ELECTRIC LIGHT IN MINES.

AMONG the future possibilities of the electric light, there is probably none which possesses more interest than its adaptation to the lighting of mines. The advantages which must follow its use in this way are at once obvious. Darkness and fire-damp between them will account for the majority of the more serious as well as for many lesser accidents to miners, and they are dangers which cannot better be avoided than by the general adoption of a mode of lighting which ensures at once brilliant illumination and the perfect exclusion of gas currents from the lamp flame. Now that the one disqualification which can be urged against the electric light—namely, that it does not serve as a test for gaseous impurity in the air of the mine—has been removed by attaching indicators to the lamps used underground, we may indulge a hope that the cost of introducing new lights and electric machinery will not long be allowed to oppose this much-needed reform.

ENDEMIC GOITRE IN CENTRAL ASIA.

SURGEON G. M. GILES, M.D. Lond., surgeon to the I.G.S. *Investigator*, who was sent on special duty with Colonel Lockhart's Mission to the Gilghit and the Paman Plateau, furnishes an interesting paper to the *Indian Medical Journal* on the Prevalence of Goitre among the Denizens of the Highlands of Central Asia. Dr. Giles is inclined to attribute the disease to the habits of the people who live in dark mud huts with no entrance for light but the door, and to the absence of trees on the surrounding hills. He speaks very highly of the treatment by injections of iodine into the cysts at intervals of a week or so, and lays great stress on the use of a watery, not an alcoholic, solution of the drug. His highly favourable opinion of the efficiency and harmlessness of iodine is founded on the result of some three hundred injections.

DENTAL SURGERY ON THE CONTINENT.

ACCORDING to the *Independent Practitioner*, in Austria and Hungary there were until lately no dentists, medical men alone being allowed to practise dentistry. Before the year 1876, in order to practise dentistry in Holland, it was necessary to hold the diploma of medicine, surgery, and midwifery. The law has now been amended, a special course of study and special examinations having been provided for, as in Germany, Russia, and Switzerland. Is not this non-insistance on medical qualification rather a retrograde step?

THE "JACOB" TESTIMONIAL.

THE subscriptions to the Jacob testimonial fund which have been handed in or promised up to the present amount to about £210. The lengthy list of subscribers shows how general and widespread is the desire of the profession to mark in an appreciable way its esteem for Dr. Jacob.

THE DISCUSSION ON RABIES AT THE FRENCH ACADEMY.

THIS debate, says our Paris correspondent, whose letter we are obliged, from want of space, to hold over, was concluded on Tuesday last. M. Peter read particulars of two new cases in which death had occurred from rabies after the intensive inoculations. M. Vulpian praised Pasteur's work, and criticised the statements and conclusions of M. Peter; after which M. Brouardel spoke, and the discussion terminated.

FILARIA SANGUINIS HOMINIS.

DR. STEPHEN MACKENZIE gave, at the Clinical Society on the 14th inst., a most successful demonstration of the living filariæ from the blood of a gentleman—a member of the medical profession—suffering from chyluria. The microscopical preparations were seen by a large number of members of the Society.

M. BLONDIN.

VIEWED from a physiological point, the performance of M. Blondin at the Agricultural Hall must be regarded as one of the marvels of the age, which grows more wonderful every year. Such feats as his are remarkable when done by men of twenty, but done at the "grand climateric" they are trebly so. Though on close inspection it is seen that M. Blondin bears marks of age, his step on the rope, and his self-command in a "poke" or on his bicycle, are as perfect as ever.

FOREIGN UNIVERSITY INTELLIGENCE.

Dorpat.—The Heimburger prize, amounting to about £50, has been awarded to a former Dorpat student, Dr. Erich Harnack, Professor of Physiological Chemistry and Pharmacology in Halle, for his treatise on Materia Medica and Prescribing.

Gratz.—For the vacant Professorship of the Diseases of Children the names of Drs. Soltmann of Breslau, Epstein of Prague, Von Hüttenbrenner of Vienna, and Tschumer of Gratz have been brought before the Medical Faculty. For the Professorship of Ophthalmology, vacated by Prof. Blodig, the claims of Drs. Becker of Heidelberg, Eversbusch of Erlangen, Sattler of Prague, and Schnabel of Innsbruck having been considered, the last was invited to accept the chair.

Groningen.—The death is announced, at the age of thirty-eight, of Dr. Johann R. Ranke, Professor of Surgery. The

Digitized by Google

deceased professor was a German by birth, and was formerly assistant to Prof. Volkmann.

Kieff.—Dr. D. V. Chirkoff of Moscow has been appointed Professor of Special Therapeutics.

Madrid.—The death is announced of Dr. Gonzalez Encinas, Professor of Clinical Surgery, and one of the most distinguished operators in Spain.

Naples.—A Professorship of Orthopædic Surgery has been established.

Paris.—M. Pajot has resigned the chair of Midwifery owing to his advanced age. M. Farabeuf has been appointed Professor of Anatomy, in succession to M. Sappey. M. Gabriel has been appointed Professor of Physics, in succession to M. Gavarret. M. Dieulafoy has been elected to the chair of Internal Pathology, in succession to M. Hardy. M. Moisson has been appointed Professor of Toxicology in the École Supérieure de Pharmacie. M. Chatin has been chosen Assistant Professor of Zoology in the Faculty of Sciences.

DR. WILLIAM PERRY, of Exeter, N. H., the oldest living graduate of Harvard, celebrated the ninety-eighth anniversary of his birthday on the 22nd ult. Dr. Perry is the sole survivor of the passengers on Robert Fulton's steamboat on its trial trip down the Hudson seventy-nine years ago, and he was a member of the class of 1811 at Harvard College, of the members of which there is only one other survivor.

IN connexion with the outbreak of small-pox on board the German steamer *Preussen* from Southampton to Adelaide, we are requested to point out that although foreign steamers call at British ports to embark passengers, they do not necessarily come under the sanitary supervision which the Board of Trade exercises over British steamers under the Passengers Act.

CHOLERA is now prevalent on both sides of the continent of South America. It has increased in Chili, where it is fatally spreading in the province of Valparaiso; and it has since been reported to have broken out at Monte Video, in Uruguay. Situated as Monte Video is at the mouth of the river La Plata, considerable commercial interests are likely to be involved.

A NEW bi-monthly publication, devoted to the Diseases of Children, the *Centralblatt für Kinderheilkunde*, will be published in Vienna on the 1st of March next. The editor is Dr. R. W. Raudnitz, and the English collaborator, Dr. H. Ashby of Manchester.

BY the death of Colonel Bolton, which we announced last week, the office of Water Examiner under the Metropolis Water Act has become vacant. This is really an important public health appointment, and should be held by a medical man having special knowledge and experience in sanitation.

AT the next meeting of the Hunterian Society, on Wednesday, January 26th, Mr. Croft will contribute a paper on the Immediate Treatment of Fractures, and give a demonstration of his mode of applying plaster-of-Paris splints.

IT is satisfactory to have to announce that the Naval Medical Good Service Pension of £100 a year has been awarded to Sir William Smart, K.C.B., the senior officer on the retired list of Inspectors-General.

THE Berlin police department is doing its best to discourage the sale of quack medicines by issuing warning notices to the public.

AN International Health Exhibition, referring especially to foods and cooking, under the presidency of M. Chevreuil, is to be held next month at Lyons. It will be open from the 20th to the 28th proximo.

THE annual general meeting of the Neurological Society will be held at the National Hospital, Queen-square, at 8.30 P.M. on Thursday, January 27th. The President-elect is Dr. Samuel Wilks, F.R.S.

IN many parts of Bavaria diphtheria has been very rife. It is thought that fully 10,000 children have been affected there being 3000 in Bamberg alone. In several localities the schools have been closed.

A SUCCESSFUL meeting of the Association of General Practitioners was held in Exeter Hall on the 19th inst. We hope to publish in our next issue a detailed account of the proceedings.

IN the Eghri-Capon quarter of Constantinople there is at present a great deal of small-pox, some forty-five deaths having already occurred.

WE are glad to hear that a matter which has excited much painful interest in one of our northern universities has been satisfactorily settled by apology and retractation.

Pharmacology and Therapeutics.

BROMIDIA.

BROMIDA, a sample of which has been forwarded to us by Messrs. Roberts of New Bond-street, is a combination of bromide, chloral, hyoscyamine, and cannabis indica, and is acknowledged to be a valuable hypnotic. The combination seems to be peculiarly efficient, for cases of insomnia have been relieved by it when each of the drugs mentioned had individually failed.

DIFFERENT METHODS OF TREATING CERVICAL CATARRH.

Dr. L'voff of Kazan has reported in the *Meditsinskoe Obozrenie* a number of observations made on the comparative value of different methods of treating catarrh of the cervix uteri. The total number of cases was eighty-two. Of these thirty-six were treated by mechanical scraping of the mucous membrane, eighteen by means of powerful caustic applications, and twenty-eight with weak caustics. The method of applying the weak caustics was, after washing out the vagina with warm water or a solution of boracic acid, to swab the cervical canal with tincture of iodine or with a 10 per cent. solution of chromic acid. This was done once a week, plugs soaked in glycerine of tannin being also used every other day. The strong caustic application consisted of a bougie made of sulphate of zinc and alum fused together. This was allowed to remain in the canal till it had all dissolved, which took place usually in one or two hours. Afterwards the mucous membrane presented a white appearance, due to the eschar. This fell off in five or six days, during which time warm vaginal douches were administered and plugs of glycerine and iodoform inserted every alternate day. In the cases treated by scarification an iodoform and glycerine plug was left in for twenty-four hours, and the patient was then sent home. The results of these different methods of treatment were that the mild caustics ultimately effected a cure, but required at least two months to do so; while the severer methods—that is to say, the fused zinc and alum and the scarification—produced a permanent cure in about a fortnight. The author adds that no unpleasant symptoms were caused by either the caustics or the scarification in any of the eighty-two cases.

RUSSIAN PEPSINE

The comparative value of different preparations of pepsine and papaine as peptonising agents has recently been investigated by Dr. Lipski of St. Petersburg. He finds that the

Digitized by Google

best of all the dry preparations he tried was the pepsinum saccharatum siccum of the Russian Pharmacopœia, 2 grms. of which, when freshly prepared, digested 9·53 grms. of albumen. From his results it appears that the Russian pepsines are far more active preparations than most of those in use in western continental Europe. Dr. Lipski did not apparently make any determinations of the value of any English or American preparations.

ANTIFEBRINE IN TYPHOID.

Antifebrine has been used a great deal in Professor Kotovshcheski's clinic in Kazan in typhoid fever cases with good results. After a single four-grain dose, the temperature sank in the course of an hour 0·9° to 2° C., the reduced temperature persisting for from an hour and a half to three hours. It was found that by repeating these four-grain doses every two hours the temperature could be kept at the normal point all day. The frequency of the pulse was at the same time diminished and its tension increased. The excretion of urea was also augmented. The patients liked the drug, and no ill effects were ever observed from its use.

SALICYLIC ACID IN FOOD.

M. Vallin has presented a report to the French Government on the employment of salicylic acid in articles of food, in which he states that medical observation has established that even small quantities of salicylic acid, or its derivatives, if taken constantly, are capable of affecting the health of certain subjects who are peculiarly susceptible to the influence of this drug, as also the health of aged persons and those whose renal and digestive organs are not perfectly sound. He consequently advises that the addition of salicylic acid and the salicylates, even in small quantities, to solid and liquid articles of food should be prohibited.

ICHTHYOL IN ERYSIPELAS.

Dr. Nussbaum of Munich has recently obtained strikingly successful results in traumatic erysipelas by the use of an ointment composed of vaseline with 10 per cent. of ichthyol, a chemical substance rich in sulphur, obtained from mineral oil, which was introduced by Dr. Unna a few months ago, and which was found useful by Dr. Dubelir of Moscow in acute and chronic rheumatism (see THE LANCET, Oct. 2nd, 1886) both as a medicine and as an external application. Dr. Nussbaum found, as indeed Dr. Dubelir also remarked, that the ichthyol had an irritating effect on the skin, so that it could not well be borne for more than three days, but as this was long enough to effect a cure in all the cases no difficulty on this head arose.

PULVERISED SPLEEN IN CHLOROSIS.

The German medical papers quote some observations made by Dr. Predazzi at Prof. Maragliano's request, on the value of treating chlorotic patients with an emulsion of pulverised spleen, bitter almonds, and brandy. In the five cases in which this was adopted, rapid improvement took place both in the general condition of the patients and in the physical signs; that is to say, the number of red blood-corpuscles was increased, as also the arterial tension and the body weight. The author does not attempt any explanation of the action of this singular remedy. The quantity of "polp. splenic." given daily was about five ounces, and it was ordered at meal-times.

PROTECTIVE INOCULATION FOR BOVINE CONTAGIOUS PLEURO-PNEUMONIA.

THE animal plagues which have for so many years committed such havoc among our flocks and herds are gradually becoming amenable to the measures of sanitary police devised for their limitation and ultimate suppression. Indeed, one of the most troublesome and costly of these maladies—that popularly known as the foot-and-mouth disease—seems to be entirely eradicated from our soil after harassing cattle-owners since 1839, as no cases have been reported in the three kingdoms for several months. But its companion disease, the so-called lung-plague, or "pleuro," as the dairymen and butchers designate it, which appeared in Great Britain in 1842, yet lingers in some parts of the country, and particularly in Scotland, in spite of the efforts of local authorities. This disorder has been a most serious scourge, not only in the United Kingdom, but also on the European continent, notably in Holland (which has now, however, stamped it out), from which country it was originally introduced into our own. Within the last thirty years it has been carried into nearly every part of the world, and its desolating effects are now being experienced in South Africa, Australia, and the United States of America. The difficulty in suppressing it is mainly due to its insidiousness—the invasive stage being most difficult to detect—the uncertain duration of incubation; and the fact that an animal which has been imperceptibly affected, or which has apparently recovered, may for a long time afterwards infect healthy cattle, owing to a necrosed piece of lung, more or less encapsuled, continuing to give off infective elements during expiration.

The disease, unlike rinderpest and foot-and-mouth disease, appears to be exclusively confined to the bovine tribe, all attempts to transmit it to other species having failed; and no authentic instances of accidental transmission to other animals or mankind, even by the ingestion of the milk or flesh of diseased cattle, are recorded.

In order to diminish the ravages of this lung-plague, protective inoculation, first introduced by Dr. Willems of Hasselt (Belgium) some thirty years ago, has been resorted to in this country, on the Continent, and in South Africa and Australia. The value of this procedure has been thoroughly established, the protection afforded by the inoculations having been demonstrated in the most marked manner during outbreaks of the disorder, and also by the experiments instituted by commissions appointed by the Governments of France and other countries. The virus for inoculating purposes is obtained from the diseased lung at a certain stage, and, as may be surmised, great care is necessary not only in collecting and keeping it, but also in introducing it into the body of the ox which is to be protected. Indeed, success or failure depends upon the skill of the inoculator, as he must not only be cognisant of how to obtain the material in its purest and most active condition but also when and where to introduce it, and how to control its action when inoculated. The infectiveness of the virus is extraordinary. If a drop of the serous fluid from a diseased lung is inserted beneath the skin of a part where the connective tissue is loose and abundant—as in the dewlap of the ox—the effect is most serious, death being the result in almost every case from rapid extension of the morbid process set up to vital organs. To obviate such unfortunate accidents, the extremity of the tail is now selected, as there the connective tissue is scantier and denser than elsewhere; and when the morbid action threatens to extend to the body, timely amputation of a portion of the organ—necessitated by certain indications manifesting themselves beyond the seat of inoculation—at once checks it.

Protective inoculation can be resorted to with great advantage when a district or country is invaded by the disease, and slaughter of all the cattle therein would prove a serious calamity. Even in the case of valuable herds, when the disease has only attacked one or two animals, and it is of great importance that its extension should be checked and the remainder of the cattle saved, there is good reason for the adoption of the measure; though the "stamping-out" method, entailing the slaughter of all, has its advocates. These urge the danger of allowing cattle to live which may, through contact with the sick, have only a small portion of lung involved, present no symptoms, are inoculated, and so are supposed to be safe to place among others, while all the time they are capable of infecting. This is really the danger attending the practice of inoculation, a danger not easily avoided, because of the difficulty of thoroughly exploring the thoracic cavity of the ox, owing to the thick skin and parietes, and the unfavourable position of the animal for examination.

There seems to be no danger of infection from cows during the inoculation period, no reliable evidence having been adduced that this operation tends to spread the disease, or to maintain it in districts where it is prevalent. On the contrary, there are numerous instances recorded in which the extension of the scourge in a cowshed has been stopped in a few weeks after inoculation has been practised, and the inoculated cattle have resisted subsequent infection under the most favourable conditions for receiving it. Holland has been freed from lung-plague by energetically slaughtering the diseased and inoculating the unaffected, and France has adopted the same course. In this country no experiments of a public kind have been instituted to set at rest the value of protective inoculation for this malady, and notwithstanding strong evidence in

Digitized by Google

its favour, its adoption is strongly opposed by those who favour the expensive, but thoroughly effective, plan of wholesale slaughter of the sick and suspected, the latter including all the cattle which have been directly or indirectly in contact with the former.

PHTHISIS IN THE ARMY.

AT the Statistical Society on Tuesday evening a paper was read by Robert Lawson, Esq., LL.D., Inspector-General of Hospitals, on the Mortality among Troops serving in the United Kingdom from Consumption. After stating the sources from which the rates of mortality from phthisis in the army and in civil life respectively were obtained, the author showed in a tabular form the ratio of deaths in civil life from this disease at five periods of life between seventeen and forty-five in the five years 1838-42 and the seven quinquenniads 1850-84. The decrease in the mortality from phthisis in the later periods he considers to be mainly attributable to hygienic measures, and perhaps to some extent also to more successful medical treatment. In making a comparison of the death-rates in the army with those in civil life, the author pointed out the necessity of adding to the military deaths a certain proportion, which he shows reason to estimate at one-half, of the men discharged the service in each year on account of consumption. Calculating the ratio of deaths upon the numbers living, and bringing it into comparison with the proportion which would have occurred in civil life in a population with the same age distribution as the army, the following results were obtained:—

Periods.	Phthisis in army at civil rates.	Phthisis observed.		
		Deaths.	Half of discharges.	Total deaths.
1837-46	5·09	8·53	0·85	9·38
1860-64	3·63	3·07	2·70	5·77
1865-69	3·81	2·57	2·26	4·83
1870-74	3·39	2·43	2·21	4·64
1875-79	3·21	2·45	2·22	4·67
1880-84	2·70	1·92	1·71	3·63

The actual reduction in the deaths among the troops in the latter as compared with the first period is to some extent due to increased facility of invaliding phthisical cases; but with the correction made by Dr. Lawson there is still a marked progressive diminution to the extent of about three-fifths. The table, however, shows clearly that "at every period mentioned service in the army was attended by greater mortality from phthisis than would have been met with among men of the same age exposed to the ordinary causes of that disease in civil life." Dr. Lawson questions the opinion held by many of the medical officers that this decrease was to any great extent attributable to improved ventilation in barracks. He believes it to have been much more in consequence of removing a considerable number of the troops from the towns in which they were quartered to camps at Aldershot, Shorncliffe, Colchester, and the Curragh, and to an improvement in their clothing by the adoption of woollen shirts for linen or calico. He also considers the abolition of white trousers and the substitution of woollen material for them to have exercised a beneficial influence. Dr. Lawson pointed out that the mortality from consumption has decreased also among the troops in the colonies, with the exception of Mauritius and Ceylon. In a subsequent table it was shown that while so marked a decrease occurred in the general death-rate among troops at home, it was greater in deaths from phthisis than from other diseases. Instead of the former—as in 1837-46—constituting 52·3 per cent. of the whole, in 1880-4 they only amounted to 43·8 per cent.

In the discussion that followed, Dr. Longstaff, Captain Douglas Galton, Dr. Marston, Dr. Dickson, Dr. Lloyd, R.N., and others took part.

Dr. Longstaff's criticism mainly bore upon the differences between the military and civil portions of the community, rendering comparisons between them difficult, and, as affecting the statistical deductions, unreliable.

Captain Galton spoke of what had been done in effecting sanitary improvements in barracks since the time of Lord Herbert, and dwelt upon the fact that there was a great diversity in regard to these in different barracks, and even in different portions of the same barrack, rendering it difficult to gauge exactly their effect on the soldier's health.

Dr. Marston adverted to the large prevalence of ophthalmia in the army twenty-five or thirty years ago; the amount of inefficiency and invaliding it caused then as compared with the practically insignificant amount of the same disease now; and he urged that this could only have been due to the removal of a main factor in its production—viz., the effects of overcrowding and imperfect ventilation. Clothing might fairly be estimated as a cause of disease. He likewise called attention to the prevalence of pulmonary disease among the crews of ironclads years ago, and to the prejudicial effect of crowded and badly ventilated buildings in causing these diseases, as proved by his experience in India and Afghanistan. He traced the operation of the same factor in affecting the incidence and prevalence of epidemic disease generally, and cited some illustrations.

Dr. Dickson and Dr. Lloyd, R.N., followed, and Dr. Lawson in his reply, after meeting Dr. Longstaff's criticism, explained, in effect, that owing, no doubt, to the difficulty of grasping the points in a statistical paper of this kind some misapprehension had arisen. He did not at all depreciate the effect of sanitary improvements, but he had endeavoured to point out some of the directions in which these had operated that had not hitherto received due attention.

BRITISH MEDICAL BENEVOLENT FUND.

THE annual general meeting of subscribers to this Fund was held on Monday, Jan. 10th, at 34, Seymour-street, Portman-square, the residence of the treasurer, at 4 P.M., when the chair was taken by Dr. Jonson, chairman of the committee, in the unavoidable absence of the President, Sir George Burrows, Bart.

The financial statement was submitted and the annual report of the committee read, from which it appeared that the donations during 1886 had amounted to £869 5*s.* 6*d.*, subscriptions to £1228 9*s.* 5*d.*, exclusive of £226 9*s.* 1*d.* contributed from the Jubilee Fund—a total of £2324 3*s.*, which shows an increase over the receipts of 1885 of nearly £300. The disbursements during the year had been, in grants to 183 applicants, £2128; in annuities distributed amongst 61 old people, all over sixty years of age, £1074. The cost of collection and distribution of this large sum (over £5500), minimised though it is by the fact that the officers are all honorary (with the exception of the collector), amounted to £130, including stationery, collector's commission, the printing and postage of the report (of which a copy is sent to each subscriber), the postage and other expenses of the secretaries for finance and cases, and the postal and incidental expenses connected with the distribution of over £3200 in weekly or monthly instalments, which is a peculiar characteristic of this Fund, carried out by means of the Cheque Bank, and by Dr. Jonson as regards the annuities. The distribution of grants is entrusted to the various honorary local secretaries, when it can be done without imposing too irksome a burden upon those gentlemen who so kindly undertake that duty. The number of applicants for grants was 209, of whom 183 (an excess of two over the number relieved in any previous year) received sums varying from £5 to £20, and many of those inadequately relieved would have been given larger grants, had the sum in the hands of the committee been larger. Personal inquiry proved dire and distressing want in many instances amongst those who had been brought up in comparative ease and comfort, and who, by the death of the breadwinner, found themselves dependent upon charity for the common necessaries of life. If this applies to the case of those in receipt of grants, how much more must it occur in the cases of those who, in addition to want of money, are suffering from the weight of years. Of such, the list of annuitants affords many an example, and well shows the infinite good wrought by this charity. The celebration of the Jubilee Year by a banquet in July, under the presidency, and aided by the distinguished advocacy, of Sir James Paget, including a donation of £100 from Her Majesty the Queen, resulted in the addition of £3000 to the funded property from which the annuity payments are derived. This splendid addition will allow of the creation of new

Digitized by Google

annuities and a consequent relief to the donation or grant department.

Mr. Brett of Watford joined the Committee of Management, in the place of the late Dr. Harvey Kowen, a liberal contributor during his lifetime, and the generous donor of a legacy of £500. The names of Dr. Coates of Bath, Dr. Matthews Duncan, and Dr. R. Quain were added to the list of Vice-Presidents of the Fund, in recognition of their liberality.

THE ERASMUS WILSON BEQUEST.

The following memorial, to which we alluded last week, has been addressed to the President, Vice-Presidents, and Council of the Royal College of Surgeons of England:—

"GENTLEMEN,—We, the undersigned, being informed that a legacy of a considerable amount has been bequeathed to you by the late Sir Erasmus Wilson for the benefit of the College, and presumably for the advancement of science, beg respectfully to direct your attention to the need of support of those collateral branches of medicine which can only flourish by liberal pecuniary aid. We would, therefore, submit to you the desirability of founding an institution under the direction of the College which shall have for its object "physiological and pathological research." The want of such an institution in England has long been felt, and more especially of late, when we have had to look to Berlin for information respecting tubercle and to Paris for experiments on the prevention of hydrophobia. It is a national discredit that we have nothing in London like the splendid laboratories which exist not only in the capital cities of Europe, but in comparatively small towns, such as Bonn, Strasburg, and Leipsic. There is little prospect of the Government establishing such an institution, or of its being founded by public subscription; the only hope of its foundation lies in the possible bequest of a large sum of money to be devoted to scientific uses. An opportunity has now occurred which has put it in the power of the College to carry this into effect, an opportunity which if now lost may never recur. The foundation of an institution of this nature would tend to raise England to the scientific position held by France and Germany, would create a body of men anxious to devote themselves to scientific work, would be in accord with the best wishes of the donor, and would place the Royal College of Surgeons of England amongst the foremost institutions of Europe. The President and Council would be doing much to their honour if, when an endeavour is being made to strengthen the Empire by a consolidation of the Colonies, they founded an institute in the mother country which should draw to it students from all parts of Her Majesty's dominions.

"We remain, gentlemen, yours obediently,

John Eric Erichsen, F.R.C.S.; J. Hughlings Jackson, M.D.; Sir Henry Thompson, F.R.C.S.; Sir J. Fayrer, K.C.S.I., M.D.; David Ferrier, M.D.; Sir William W. Gull, Bart., M.D.; W. Watson Cheyne, F.R.C.S.; Francis Galton, M.A.; Geo. H. Savage, M.D.; George Pollock, F.R.C.S.; Sir Jas. Risdon Bennett, M.D.; P. H. Pye-Smith, M.D.; John Simon, C.B., F.R.C.S.; E. Klein, M.D.; Sir Henry W. Acland, K.C.B., M.D.; George J. Romanes, F.R.S.; F. W. Pavy, M.D.; W. H. Flower, F.R.S.; Sir Andrew Clark, Bart., M.D.; Sir W. Bowman, Bart., F.R.S.; Richard Quain, M.D.; Gerald F. Yeo, M.D.; George Fleming, LL.D.; W. H. Broadbent, M.D.; Thos. Stevenson, M.D.; Victor Horsley, F.R.C.S.; Sir Edward H. Sieveking, M.D.; T. Lauder Brunton, M.D.; E. A. Schäfer, M.R.C.S.; W. Withers Moore, M.D.; Robt. Cory, M.D.; H. N. Moseley, F.R.S.; E. Ray Lankester, F.R.S.; R. Brudenell Carter, F.R.C.S.; Charles E. Groves, F.R.S.; Thomas H. Huxley, F.R.C.S.; Arthur Gamgee, M.D.; John Tyndall, F.R.S.; Sir John Lubbock, Bart.; Jos. D. Hooker, F.R.S.; W. T. Thiselton Dyer, F.R.S.; Shirley F. Murphy, M.R.C.S.; M. Foster, M.D.; J. Burdon Sanderson, M.D.; Charles S. Roy, M.D.; Francis Darwin, M.B.; Hugo Müller, F.R.S.; J. N. Langley, F.R.S.; W. H. Corfield, M.D.; W. H. Gaskell, M.D.; Donald MacAlister, M.D.; Samuel Wilks, M.D.

(The last-named gentleman acted as secretary.)

The memorial was, as we announced last week, referred to a committee on the question as to the disposal of the fund under the will of Sir Erasmus Wilson.

HEALTH OF THE METROPOLITAN POLICE.

SIR CHARLES WARREN states the "authorised strength on Dec. 31st, 1885," to have been 13,319, but nowhere in the report is the average strength throughout the year given. Of this strength, 12,586 were employed in the metropolitan divisions, and 733 in the dockyards and military stations of Woolwich, Portsmouth, Devonport, Chatham, and Pembroke. The Chief Surgeon reports that "the total number of separate individuals who were on the sick list during the year 1885" was 6328, but he does not state how many cases occurred, nor does he give any information respecting the diseases from which the men suffered or the number constantly off duty on account of sickness. There were 204 men admitted into general or special hospitals, and 20 into naval hospitals during the year, but there is nothing to show whether these were included in the number stated above. The deaths amounted to 66, of which 16 occurred in hospitals; 1 man shot himself, 1 was drowned, 1 was killed by accidentally falling downstairs, and 3 died from fractures, in one case complicated with delirium tremens. The proportion of deaths to strength for the whole force was 4·96 per 1000; only one of the deaths occurred among the men employed in the dockyards. The death-rate in the metropolitan divisions was 5·16 per 1000 of strength, a ratio which compares favourably with previous periods. In the five years 1852-6, it amounted to 7·6, or excluding deaths from cholera, which was epidemic in 1853–4, to 7·4 per 1000, and in 1880 it was 6·4 per 1000. Of the 65 deaths in the metropolitan divisions, 31 were caused by pulmonary diseases, being in the ratio of 2·46 per 1000 of the strength, and lower than in either of the two previous periods. The men removed from the force on account of being "incapacitated by sickness or long service" amounted to 222, or 16·67 per 1000. This is very much below the proportion returned as "invalided" in previous reports, having been 35 in 1852–6 and 25 in 1880; but there may probably be some difference in the mode of recording the discharges at these different periods. In the present return the cause of invaliding is stated in only 163 cases; 44, or upwards of one-fourth, were assigned to rheumatism, rheumatic gout, and sciatica; 22 to long service, age and debility; and 16 to pulmonary diseases. So far as we can judge from the information afforded by the returns, the health of the force has been very satisfactory.

THE PARKES MUSEUM.

THE annual report of this institution, which was presented at the general meeting in December, shows conclusively that the work which is being done by the museum is of a kind calculated to be of great utility to the public. Since its inception, now nearly eleven years ago, the annual records of the work done have none of them, we think, equalled the record of 1886 for real solidity in its accomplished facts. Early in the year 1886 it was suggested that a course of lectures should be given intended to meet the requirements of persons desirous of qualifying for such offices as that of inspector of nuisances, &c. No difficulty was found in arranging these lectures. Professors de Chaumont, Corfield, Robinson, Messrs. Eassie, Percy, Boulnois, Shirley Murphy, Wynter Blyth, Sykes, and Cassal each expressed their readiness to help by delivering one or two lectures intended to form part of a coherent course, and it is no wonder that with such a well-qualified staff the lectures became popular. A fee of 5*s.* was charged, with the result that some sixty persons attended the course; and when, as was necessary, the course was repeated in the autumn, seventy-five persons were found who were eager to pay the small fee and listen steadily to the instruction offered. This is work of the right kind, and work which, as we have said above, must benefit the public. The lectures are admirably calculated for the audiences to which they are delivered, and the museum affords abundance of material with which to illustrate them. In lectures such as these the museum finds its true mission. The collection is not one calculated to attract the public at large, and it is obvious that the person who is ignorant in sanitary matters would fail to appreciate the exhibits, many of which are of a very technical character. When, however, the lecturer

Digitized by Google

and the museum collection become mutually complementary to each other the value of each is enormously increased.

The ordinary lectures to the members were well attended.

Most of the recognised teachers of hygiene brought their classes to the Museum for practical instruction.

The library, we are told, has been enriched during the past year by 450 books and pamphlets, and the card catalogue is completed, so that the work of reference is easily carried on. Those of our readers who issue annual reports on sanitary subjects would do well to remember the importance of sending such reports to this central library devoted to sanitation, which is yearly becoming of more and more importance.

The lectures for the ensuing year are to be given, not as heretofore in the evening, but at five in the afternoon—an hour which it is hoped may prove convenient to the majority of members and their friends. The first lecture is arranged for Thursday next, Jan. 27th. The lecturer is Mr. Ogle Tarbotton, M.Inst.C.E., and the subject is "Engineering and Architecture in relation to Sanitary Science." Captain Douglas Galton, F.R.S., will occupy the chair.

ADULTERATION OF FOOD AND DRUGS ACT.

A SPECIAL general meeting was held on Jan. 12th at the Lecture-room of the Sheffield Pharmaceutical and Chemical Society, Norfolk-row. The meeting was called "to consider the recent ruling at Sheffield Town Hall under the 'adulteration of Food and Drugs Act.'" The chair was occupied by the President, Mr. Newsholme, and there was a large attendance, the room being almost filled.

The Chairman proposed the first resolution, which was as follows: "That this meeting, specially convened, views with alarm the recent decision of the Sheffield stipendiary magistrate 'that a preparation containing *any* opium and *any* alcohol whatever may be legally sold as tincture of opium'; and this meeting is of opinion that if this be upheld as legal, and is acted upon, it is likely to interfere dangerously with uniformity and with the public safety. It would further affirm that the only tincture of opium acknowledged generally by the trade is that of the British Pharmacopœia."

The resolution was carried unanimously, as was also the following:—

Moved by Mr. Ward, F.C.S.: "That this meeting expresses also its astonishment at the judgment recently given with respect to paregoric, that any preparation of a soothing nature may be sold under that name. It holds that the fact of two or more dissimilar prepartions having the same name is so dangerous to public health that it is desirable the Pharmacopœia Committee should adopt, as a synonym of the compound tincture of camphor of the Pharmacopœia, that which is commonly known as paregoric, paregoric elixir, and elixir paregoric."

Moved by Mr. Preston: "That this meeting desires to point out its determination strictly to conform to the British Pharmacopœia as binding upon it, in accordance with the Order in Her Majesty's Privy Council made respecting thereto."

This resolution was carried almost unanimously, and a vote of thanks to the Chairman concluded the meeting.

ST. ANDREWS GRADUATES' ASSOCIATION.

ON Friday afternoon last, Mr. Balfour, Secretary for Scotland, and his colleague, the Lord Advocate, received a deputation of the St. Andrews Graduates' Association at Dover House, Whitehall. The memorial, signed by 789 graduates of the University, urged that an endowment be found for two additional professors—viz., a Professor of Anatomy and a Professor of Botany, so that the University may be enabled to give two *anni medici* to medical students attending the University. After completing their two years' course of preliminary and theoretical study, they could go for practical and clinical work to any of the great hospitals of the United Kingdom most convenient to them; they could then return to the University and submit themselves to examination, and thus obtain graduation and a licence to practise their profession. Dr. B. W. Richardson, President of the Association, Sir J. Crichton Browne, Surgeon-General Gordon, and Dr. Hicks, F.R.S., spoke in support of the memorial. Mr. Balfour and the Lord Advocate, in reply to the deputation, assured them that the ancient University of St. Andrews was secure of the good-will of Her Majesty's Government, and that the memorial itself and the arguments in support of it would receive due attention. They also intimated to the deputation that evidence upon the matter set forth in the memorial would be received by the Commission about to be appointed to inquire into the constitution and endowments of the Scottish Universities, and the deputation agreed to furnish this evidence to the Commission. A cordial vote of thanks to Mr. Balfour and to the Lord Advocate for their courtesy and attention was then proposed and carried unanimously.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5856 births and 4263 deaths were registered during the week ending Jan. 15th. The annual death-rate in these towns, which had increased in the preceding four weeks from 20·7, to 26·5 per 1000, declined again last week to 24·1. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·3 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 17·4 in Portsmouth, 19·3 in Bradford, 19·3 in Sunderland, and 19·8 in Oldham. The rates in the other towns ranged upwards to 30·4 in Cardiff, 30·8 in Blackburn, 31·0 in Manchester, and 31·6 in Wolverhampton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 537 and 475 in the preceding two weeks, were last week 485; they included 195 from measles, 95 from whooping-cough, 82 from scarlet fever, 48 from "fever" (principally enteric), 34 from diarrhœa, 31 from diphtheria, and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Brighton, Portsmouth, Nottingham, and Bolton; and the highest rates in Leeds, Sunderland, and Huddersfield. The greatest mortality from measles occurred in Liverpool, Wolverhampton, Newcastle-upon-Tyne, Halifax, Leicester, and Leeds; from whooping-cough in Bristol, Plymouth, Preston, Sunderland, and Huddersfield; from scarlet fever in Norwich, Bristol, Manchester, Blackburn, Sheffield, and Sunderland; and from "fever" in Birkenhead and Plymouth. The 31 deaths from diphtheria in the twenty-eight towns included 18 in London and 5 in Birmingham. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding four weeks from 416 to 731, declined again last week to 591, but exceeded the corrected average by 89. The causes of 107, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Birkenhead, Derby, and Plymouth. The largest proportions of uncertified deaths were registered in Sheffield, Halifax, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25·1 and 29·9 per 1000 in the preceding two weeks, declined again to 26·1 in the week ending Jan. 15th; this rate exceeded, however, by 2·0 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·4 and 18·0 in Greenock and Leith, to 30·9 in Glasgow and 33·3 in Paisley. The 652 deaths in the eight towns last week showed a decline of 94 from the number in the previous week, and included 26 which were referred to whooping-cough, 13 to scarlet fever, 10 to measles, 10 to diarrhœa, 7 to "fever" (typhus, enteric, or simple), 5 to diphtheria, and one to small-pox; in all 72 deaths resulted from these principal zymotic diseases, against 63, 73, and 94 in the preceding three weeks. These 72 deaths were equal to an annual rate of

Digitized by Google

29 per 1000, which was 0·2 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 15, 21, and 27 in the previous three weeks, were last week 26, of which 18 occurred in Glasgow, 4 in Edinburgh, 2 in Aberdeen, and 2 in Paisley. The 13 deaths from scarlet fever corresponded with the number in the previous week, and included 8 in Glasgow and 5 in Edinburgh. The 10 deaths attributed to diarrhœa showed a decline of 8 from the number in the previous week; 5 were returned in Glasgow and 2 in Edinburgh. All the 10 fatal cases of measles occurred in Glasgow. The seven deaths referred to "fever" corresponded with the number in the previous week; and included 2 in Glasgow, 2 in Greenock, and 2 in Paisley. The 5 fatal cases of diphtheria showed a decline of 12 from the numbers in the previous week; 4 were returned in Glasgow. The death referred to small-pox was a fatal case of chicken-pox in Glasgow. The deaths from acute diseases of the respiratory organs in the eight towns, which had been 179 and 213 in the preceding two weeks, declined again last week to 181, but exceeded the number in the corresponding week of last year by 36. The causes of 86, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 38·0 and 31·3 per 1000 in the preceding two weeks, rose again to 36·2 in the week ending Jan. 15th. During the thirteen weeks of last quarter the death-rate in the city averaged 26·7; the mean rate during the same period did not exceed 18·8 in London and 19·5 in Edinburgh. The 245 deaths in Dublin last week showed an increase of 33 upon the number returned in the previous week, and included 8 which were referred to scarlet fever, 7 to diarrhœa, 4 to "fever" (typhus, enteric, or simple), 2 to whooping-cough, and not one either to small-pox, measles, or diphtheria. Thus the deaths from these principal zymotic diseases, which had declined in the preceding five weeks from 23 to 13, rose again last week to 21; they were equal to an annual rate of 3·1 per 1000, the rates from the same diseases being 2·3 in London and 2·4 in Edinburgh. The fatal cases of scarlet fever, which had been 11 and 6 in the preceding two weeks, rose again last week to 8; the deaths from diarrhœa and diphtheria also showed an increase upon the numbers in the preceding week; while those from "fever" showed no variation. The deaths both of infants and of elderly persons showed a considerable increase upon the numbers in the previous week. Five inquest cases and 5 deaths from violence were registered; and 82, or more than a third, of the deaths occurred in public institutions. The causes of 41, or more than 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the following promotions made by the Governments in India:—Surgeon-Major James Hunt Condon, M.D., of the Bengal Medical Establishment, and Surgeon-Major Edward Sexton, M.D., of the Bombay Medical Establishment, to be Brigade Surgeons.

ADMIRALTY.—The following appointment has been made: Surgeon Ernest Apthorpe, to the *Bullfrog*.

RIFLE VOLUNTEERS.—1st Dumbartonshire: Acting Surgeon William Mackie resigns his appointment.—1st Elgin: Acting Surgeon D. Hardie resigns his appointment.

THE CROYDON SEWAGE FARM.—The Beckenham Local Board have given instructions for an injunction to be applied for to restrain the Croydon corporation from continuing to use their sewage farm at South Norwood. It is alleged that the farm causes an intolerable nuisance, and is prejudicial to the health of the locality. The Beckenham board will, it is stated, probably be joined in the application by other adjacent local authorities.

PERILS OF JUVENILE PARTIES.—It is stated that after a juvenile ball given by a well-known Spanish nobleman, seventeen of the children who had been present were found to be suffering from measles, one of the little guests having only just been convalescent from that affection.

Correspondence.

"Audi alteram partem."

"FEVER CASES IN GENERAL HOSPITALS."

To the Editors of THE LANCET.

SIRS,—In your short article, on page 83 of your issue dated 8th inst., approving the decision of the governors of the Sussex County Hospital, situated in the borough of Brighton, to exclude in future cases of typhus, scarlatina, and measles (small-pox is already proscribed) from the hospital, you do not appear to have been fully informed as to the ample provision which has been made by the Corporation for the isolation and treatment of these and other infectious diseases. Will you, therefore, allow me to supplement this deficiency, and to put your readers in possession of the cardinal facts relating to the question.

About six years ago the Town Council—which is the sanitary authority of the borough—purchased ten acres of ground to the north of the town or on the Downs, well removed from all human habitations, and in due course proceeded to erect thereon a commodious sanatorium at a cost of about £13,853, so arranged and divided as to enable the sanitary committee, assisted by the health officer, to cope not only with the ordinary, but also with any extraordinary, demands that might be made upon its resources. The administration block provides accommodation for the physician, matron and steward, nurses, and female servants. The numerous wards and the convalescent rooms can be separately heated at any moment, and maintained at any temperature required. The ventilation is unimpeachable. The arrangements are such that each form of contagious disease can be effectually quarantined from all other types. The sexes are also separated. So that there are two wards assigned for each variety or type of fever, each being equipped with its own nursing establishment and other necessary appointments. Any of these compartments can be fumigated and disinfected with ease; and, as a matter of precaution, this is repeatedly done to make assurance doubly sure. The disinfecting apparatus is open for the use of the public as well as for that of the inmates of the sanatorium. There is an efficient laundry. Telephonic communication exists with the porter's lodge, the Town Hall, and one of the police stations. For the extinction or limitation of fire, hydrants have been fixed, and are periodically inspected and reported upon, like others in the town, to the Watch Committee. A Lewis hand fire-extinguisher is suspended in every ward.

From the foregoing summary, it will be gathered that, as regards the town of Brighton, the quarantine afforded is all that can be desired. The public are still further protected by the employment of an ambulance for the transport of patients and their infected clothing &c., and by its thorough disinfection after being used. The risks involved in conveying in cabs persons suffering from infectious disease are thus avoided. As regards the different kinds of fever, the segregation on the spot, and the periodical purifications of the wards &c., are about as perfect as they can be made.

During the meeting of the British Medical Association here in August last, the hospital was visited by a large number of medical practitioners and health officers, who, without exception, accorded to its management and organisation their full and unqualified approbation. Then there were only four patients. The numbers have seldom exceeded, at any time, a very minute tithe of those for whom provision can be made at the shortest notice. But, seeing that Brighton has occasionally suffered from want of a refuge of this description, the Corporation, in the exercise of the sanitary powers vested in them, have doubtless acted wisely and well, in providing, on a large and liberal scale, readily admitting of much elasticity either in the direction of expansion or contraction, for every emergency.

The commissioners of the adjoining town of Hove have lately opened their splendid Sanatorium which, with the ground, it is believed, cost about £10,000. It is placed at a safe distance, and convenient enough to Aldrington and Portslade—both rising and growing communities; and it may probably be eventually utilised by the inhabitants of these places as well as by those of Hove.—Yours truly,

JOSEPH EWART, M.D.,
Chairman of the Sanitary Committee,
Brighton Town Council.

Brighton, Jan. 14th, 1887

THE PROVIDENT PRINCIPLE AND THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—In condensing into a single paragraph in your leading article in THE LANCET of to-day the proposals for united action between hospitals, general and special, and dispensaries, provident or otherwise, in each district of London, contained in my Sturge Prize Essay, you do, I think, some injustice (quite unintentionally, I am sure) to an idea for which I lay no claim of originality, it having been expressed in both the other successful essays, and possibly in many others of the seventy or eighty which were not successful. The following passage will place the matter before your readers in its true light:—

"If the managers of hospitals desire, as no doubt they do, to have their incomes increased in proportion to the needs of an enormously increased and still increasing London, they must be prepared to abandon the policy of isolation which leads each institution to appeal for itself alone, and to act as if unconscious of the presence of other medical charities in its neighbourhood. The union, for certain purposes, of a group of general and special hospitals and dispensaries in each district of London is to be advocated on many grounds, not the least of which is that it would greatly facilitate the making of effective appeals for funds in a systematic manner. It would also render it easier for the public to distinguish between useful and useless charities, and for hospital managers to compare the different modes of keeping hospital accounts, and of making appeals to the public, with the object of securing the general adoption of what seemed to be the best. It would be almost a necessary preliminary to the systematic workshop collections advocated above, as it would render it possible to offer subscribers the option of going to any of the united medical institutions in their district. A further step in advance would be the union of these various groups under one council with a central office."

I must not trespass on your space so far as to explain what are the "systematic workshop collections" mentioned in this passage, but I shall be happy to send a copy of the essay to any of your readers interested in the subject.

I am, Sirs, yours faithfully,

Southville Park Villas, Jan. 15th, 1887. H. NELSON HARDY.

THE MEDICAL REGISTER.

To the Editors of THE LANCET.

SIRS,—With reference to my communication as to the registration of the diploma of Member of the King and Queen's College of Physicians in Ireland, and the degree of Master in Obstetrics of the Universities, which appeared in THE LANCET of Dec. 25th, I have since that time been engaged in correspondence with the English and Irish Offices of the Medical Council as to the refusal of the Registrar of the Branch Medical Council for Ireland to carry out Clause 20 of the Medical Act, 1886. The result is that these qualifications are now registrable in England, Ireland, and Scotland, and I understand that those already on the Register can have these additional qualifications appended to their names in the Register for 1887 by making application to the Registrar for Ireland during the next week or ten days.

I am, Sirs, yours &c.,

Dublin, Jan. 15th, 1887. C. FREDK. KNIGHT, M.D.

"SCHOOL-MADE CHOREA."

To the Editors of THE LANCET.

SIRS,—Having a year or two ago acted for twelve months as honorary correspondent to one of the largest Board schools in London, I have read with much interest in THE LANCET of last week Dr. Sturges' contribution and the leading article upon the subject of school-made chores.

Dr. Sturges clearly makes out two points. First, that by neglect of the temperament of children chorea is sometimes caused by the mere distress of uncongenial work. Secondly, that when chorea has just begun in a child it often remains unnoticed, and so becomes much exaggerated by school work. The remedy for the first grievance will, I am afraid, remain far distant so long as the present system of forcing children through certain standards, irrespective of their inclination and capabilities, prevails. The second complaint, that of the neglect of commencing chorea, is only a small part of a very wide evil. The commencement not only of chorea, but of all diseases, is neglected in Board schools. No place affords so good an opportunity of studying the different stages in the development of permanent squint than a large infants' Board school. Here, also, children may be seen "growing out of" rickets, and so on. Most of us will also remember the sad case of the child who died of meningitis a few days after he had received a blow on the head for being stupid. The remedy for this state of things is obvious. What is required is a skilled medical inspection of Board schools. It is useless to trust, as at present, to the unskilled and preoccupied observations of the teachers. The Board at present has an expensive organisation for driving children into the schools, but no provision is made to ensure that the children so driven in are fit to go to school. It seems incredible that an institution such as the School Board, whose very existence depends on the value of training, should trust their pupils' health to unskilled hands. I trust that all this will soon be changed; but the change will be brought about only by the calm display of facts, such as appears in Dr. Sturges' article.—I am, Sirs, your obedient servant,

London, Jan. 1887. THOS. GLOVER LYON.

RELATION OF PHTHISIS TO OVARIAN CYSTIC DISEASE.

To the Editors of THE LANCET.

SIRS,—In reference to Dr. Bailey's case narrated in your Clinical Notes of last week's issue, I would, firstly, venture to congratulate him on his accurate diagnosis and successful treatment of a most difficult case, and, secondly, I would thank him for the information he kindly gives me on the point of the relation between phthisis and ovarian cystic disease, for which I am the more grateful because it is *not* confirmatory of the common family history of consumption. But he mentions a fact which strongly supports the theory I ventured to propound, that ovarian cysts were caused by a family tendency to early tissue degeneration. Dr. Bailey says "the patient's parents were first cousins," and how marriages of consanguinity tend to the enfeeblement of the offspring in a great majority of cases is well known. But I feel still more grateful to Dr. Bailey because many professional brethren have most kindly and courteously sent me family charts or particulars of cases in which ovarian cysts and phthisis were existent markedly in the same family, but hitherto no one has favoured me with notes of a case occurring in a member of a healthy family. Such, of course, we know do happen, and I have tried to show the importance of knowing *why*.—Yours faithfully,

West-street, Finsbury-circus, Jan. 17th. BEDFORD FENWICK.

A "NEW" METHOD OF EXCISING THE KNEE-JOINT.

To the Editors of THE LANCET.

SIRS,—I at the earliest opportunity most frankly acknowledge that the operation I thought to be my own has previously been suggested and performed by Professor Ollier. I also tender my sincere thanks to Mr. Keetley for referring me to Professor Ollier's paper in the *Revue de Chirurgie*, which I had never seen before this day. The merits of the operation I submit should in fairness be left to future clinical experience.

I am, Sirs, yours truly,

Jan. 19th, 1887. HERBERT ALLINGHAM.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—With regard to your paragraph in THE LANCET of Jan. 15th, stating that the students of St. Mary's Hospital were the first to express a collective opinion on the scheme of the conjoint Colleges for granting an M.D. degree, I think it is only right to say that on Nov. 25th, 1885, at a meeting of the University College Medical Society, attended by over one hundred students, Dr. Thomas Barlow being in the chair, an almost identical resolution to that approved by the students of St. Mary's Hospital was passed, after a long and animated discussion.—Yours truly,

J. WALTER CARR, M.B., B.S.,
President, Univ. Col. Medical Society.

University College Hospital, Jan. 16th, 1887.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE INFIRMARY.

THE special committee appointed by the governors of the Newcastle Infirmary two months ago have completed their labours and have adopted their report for presentation to the governors. The report is a very voluminous one, and at the same time critical as regards the financial position and past management of the institution. The ground it covers may be inferred from the fact that it fills nearly five columns of our daily papers here, so that I can only give you a condensation of it in this letter. The committee, in dealing with the question of admission of patients, recommend the institution of a ward for those who can pay a whole or part of the expense incurred by their keep. They point out that at present there is much overlapping of the medical charities of the city, and, for instance, recommend the removal of children, except in some surgical cases, to the new children's hospitals at Newcastle and Gateshead when these institutions are ready to receive them. As regards expense, under the head of stimulants they point out that it is in excess of all other institutions with which comparison has been made, with one exception, and they think that it ought to be capable of a reduction of at least 10s. per bed per annum, which would effect a saving of £117 in this head. In reference to the very large expense of one article of diet for the sick—viz., £747 last year for beef-tea alone,—they suggest that a better and cheaper beef-tea could be made by proper cooking. The use of rabbits in place of fowl to some extent is also recommended; and skimmed milk, they think, might be more generally used at the infirmary; also the more general use of oatmeal porridge. The recommendations of the committee as regards beef-tea are to a very great extent borne out by the special analysis of Mr. T. Hatfield Walker, analyst for the city of Carlisle, who states that when beef-tea is intended for enemata it should not be heated above 100° F. Some suggestions are made as to the nursing department, and also as regards saving under the head of antiseptic dressings, an account to be kept of the expense to each bed and to each surgeon, as at Edinburgh. A table is given, showing the number of out-patients and casuals treated in the various medical charities of Newcastle and Gateshead during the year 1885, the total amounting to 75,503. The committee are of opinion that the time has come for abandoning the letter system, and making the infirmary a free institution, and in this they have the unanimous support of the medical board. They further say that the infirmary has long been a school of practical medicine and surgery, and is not the least important factor in the success of the College of Medicine here. The number of pupils entered for the hospital practice at the present time is 115. Of these 38 are full students entered for the complete course of the College, and about 40 are from the metropolitan hospitals. At present the fees are about £1000 per annum, and are at the disposal of the honorary physicians and surgeons, with some small deductions for the infirmary library, &c. The committee think that, without interfering with the fees charged for pure clinical instruction, a charge of £5 5s. per annum should be made for each student using the infirmary, to be paid to and received by the treasurer for the benefit of the infirmary, and they refer to the custom at Edinburgh in this respect. My own opinion is that Newcastle cannot be compared with Edinburgh for many obvious reasons, and that the charge will be regarded, on the one hand, as a fine on the students, and, on the other, an attempt, and not a generous one, to lighten the pockets of the teachers. Surely £5 5s. per annum is too heavy a fine for a student's attendance at our infirmary, good as it is. I predict that this suggestion will require considerable modification before it is adopted. The committee record an investigation of cases which is of considerable interest. Of 161 cases, 41, or one-third, were reported as venereal. Of 33 cases investigated, 5 were in receipt of 5s. per week, 2 had given false addresses, 5 were in receipt of parish relief, and the remaining 21 were persons whose circumstances may be said to have justified their seeking medical relief at the infirmary, though some could afford to make some small payment to a club or provident dispensary. As to venereal cases, the committee recommend that, although only a few male patients had been admitted since 1885, when the lock ward was closed, for the future a stringent rule should be made excluding all such cases, as it is an abuse of the charity to use its funds for this purpose, and they further advise all the other medical charities not to receive them. Here the committee go rather astray, and forget, or are ignorant of, the multitude of cases which spring from this origin, and crowd out eye, throat, ear, and skin hospitals. Besides, if this is strictly carried out at the infirmary, their pupils will pass from its wards very imperfectly equipped with practical knowledge of a very valuable nature. Not very long ago I told you that the question of making the infirmary a free hospital was looming in the not very far distance. This met with an official contradiction. Well, after all, your correspondent was only very slightly in advance of the fact, which is now in a fair way of being accomplished. The committee also recommend the abolition of the casual and out-patients' department, which would effect a saving of £1000 per annum.

Newcastle-on-Tyne, Jan. 17th.

LIVERPOOL.

(From our own Correspondent.)

THE SEVENTEENTH ANNIVERSARY OF HOSPITAL SUNDAY IN LIVERPOOL.

WHEN Hospital Sunday first became an institution here we were favoured with good weather. This continued for years, and it is only recently that the weather has been so inclement. A more unfavourable day than that which marked the seventeenth anniversary could not have been imagined. The result was a great falling off in the attendance at church and chapel, and in most instances a considerable reduction in the sums collected. So strongly has it been felt that many persons were deprived by the weather of the opportunity of showing their interest in the medical charities, that additional appeals were made and offerings collected on the following Sunday, the 16th inst. The total amount of the Sunday collections, as advised to the treasurer up to the 18th inst., amounts to £4074. Many more collections have yet to be returned.

THE HOSPITAL FOR WOMEN.

A meeting of the governors of this charity was held on the 17th to elect a successor to the late Dr. Lupton. On the recommendation of the Committee, Dr. Henry Briggs, M.B. Edin., F.R.C.S. Eng., honorary medical officer to the Ladies' Charity and Lying-in Hospital, was unanimously elected. Dr. Briggs has resided in Liverpool for nearly ten years, during which he has held the offices of senior house-surgeon at the Stanley Hospital, and of resident medical officer to the Royal Infirmary. He has also been demonstrator of anatomy at the Liverpool University College, surgical pathologist, tutor in clinical surgery, and chloroformist at the Royal Infirmary. In all these he has won golden opinions both from patients and colleagues, and the governors of the Hospital for Women are to be congratulated on the choice they have made.

THE STANLEY HOSPITAL.

Drs. Costine and Sheldon, the founders of the Stanley Hospital, who have just retired from the positions of honorary physician and surgeon respectively after twenty years' service, were on the 15th inst. presented with their portraits painted in oil, as a mark of the appreciation in which they are held by the medical staff of the hospital. The presentation was made at a dinner given at the Adelphi Hotel, at which Dr. Kellett Smith presided, among the guests being Mr. Edward Whitley, M.P. For the vacancies thus created Dr. Whitford has been elected physician, and Mr. Robert Jones surgeon.

ADULTERATION OF PEPPER.

Dr. Campbell Brown, the city analyst, and Professor of Chemistry in University College, has done a great public service in detecting and exposing the manner in which pepper is largely adulterated, not only in Liverpool, but elsewhere. It would appear that the adulteration consists of the admixture of 15 per cent. of a hard ligneous tissue,

Digitized by Google

consisting of ground fruit stones, resembling olive stones. It would also appear that a worthless material resembling ground olive stones is imported from Italy, under the name of "pepperette" or "poivrette," for the express purpose of being fraudulently mixed with pepper.

NORTHERN HOSPITAL.

Dr. James Barr was on the 18th inst. elected, without opposition, physician to the Northern Hospital, in the place of Dr. Seaton, recently elected physician to the Infirmary. Dr. Barr is well known for his many contributions to medical literature.

Liverpool, Jan, 20th.

EDINBURGH.

(From our own Correspondent.)

THE LATE LORD IDDESLEIGH.

ON Tuesday last the lectures in the University were entirely omitted, as a mark of respect for the late Lord Rector, while in the afternoon a University memorial service was held in St. Giles' Cathedral, synchronously with that in Westminster Abbey, and with the funeral obsequies in Devonshire. In the Cathedral, which was very crowded, there was a large assemblage of the students, amongst whom the late Lord Rector was an especial favourite, and who were eager to pay this last tribute of respect to their twice-elected representative. The general public filled all the remaining space, with the exception of a portion of the chancel, which was occupied by University officials in their robes and insignia of office. The memorial sermon, preached by Dr. Cameron Lees, one of Her Majesty's chaplains, referred to the great loss to the University and to the cause of culture throughout the country occasioned by Lord Iddesleigh's death. A large part of the sermon dealt with the manly and noble character of the late Earl, as evidenced alike in public and in private life. A special service had been prepared for the occasion, containing appropriate selections for the choir, and the whole ceremony was of a strikingly impressive nature.

HEALTH LECTURE FOR THE PEOPLE.

A popular lecture under the auspices of the Health Society was delivered by Professor Stirling of Manchester last Saturday, and was largely attended. The lecturer chose the subject of "Wear and Tear," illustrating the transformation of energy and of material in the animal mechanism by a series of most demonstrative experiments. In an admirable way the physiological facts connected with nutrition and excretion were enumerated, illustrated by conclusive experiments, and correlated with rules for daily living of great practical importance. The demonstration was heartily appreciated by the audience, who could hardly fail to profit by the lucid exposition of the subject supplied by the lecturer.

THE ROYAL INFIRMARY.

A meeting of the contributors was held last Monday, to consider the report of their committee upon the management of the institution during 1886. The report was of a very satisfactory nature, and was unanimously adopted. It shows that in the twelve months 8088 in-patients and 25,500 out-patients have received treatment at the institution; 57 per cent. of the cases were treated in the surgical hospital, 43 per cent. in the medical house. The success of the new special departments for dermatology and throat and ear diseases is also alluded to. During the year a new observation hospital for infectious cases has been added, situated in an isolated part of the infirmary grounds; and, including this addition, the institution can now accommodate 660 inmates. The ordinary expenditure shows a distinct decrease, while the daily average of patients has been larger than in previous years. The committee report in favour of a modification of the bye-laws giving a deliberative as well as a casting vote to the chairman of the Board of Managers, which is not at present the case, an alteration in which all the parties interested concur. Comment is also made upon the thorough and efficient performance of their duties by the present staff, and the yeoman service during so many years rendered by Dr. Joseph Bell, who recently retired from the acting surgical staff of the hospital.

Edinburgh, Jan. 19th.

GLASGOW.

(From our own Correspondent.)

SOUTHERN INFIRMARY.

THE proposal to erect a third infirmary in Glasgow, to be placed on the south side of the river, where there is at present no such institution, has taken very definite shape, and may now be said to be fairly before the public. A few years ago the future of the scheme seemed to be absolutely assured by a large legacy left by a wealthy local manufacturer; it turned out, however, when the donor's estate was wound up, that there was no available balance for the proposed infirmary, so that the provisional committee are again appealing to the public for funds. It is proposed to erect only a portion of the buildings in the meantime. Plans for this have been prepared and estimates accepted provisionally. The sum which the promoters aim at raising is £20,000, and of this £8000 have already been secured. Acting in the spirit of "Bart. Rous," whose lines appear in last week's LANCET, the executive committee have approached the Town Council of Glasgow, urging the adoption of the Southern Infirmary scheme by the city as at least one of its methods of commemorating the Jubilee of Her Majesty the Queen. If this rather appropriate suggestion be adopted, and Her Majesty's consent be obtained to name the institution the "Queen's Infirmary," or the "Victoria Infirmary of Glasgow," the project will become fashionable and popular, and will soon have plenty of funds. Certainly no Jubilee memorial could be more fitting than this, or more in accordance with Her Majesty's well-known sympathies. The great need for such an institution has been amply demonstrated. The south side of the Clyde, with a population of about a quarter of a million, mostly of the working class, has not a single infirmary bed, the two existing infirmaries being situated one at the extreme northern and the other at the extreme western end of the city. That these two infirmaries are unable to cope with all the work expected of them is seen in the fact that, after filling every available bed, the average weekly number of suitable applicants waiting for admission was in 1885 no less than forty-eight, and in 1886 it was fifty-two. While that was the average number, the maximum was reached each year in February, being 120 in 1885 and 144 in 1886. Further statistics show that, while Dublin provides one bed for every 157 of her population, and Edinburgh one for every 400, Glasgow has only one for every 700, and even that is obtained here by considerably curtailing the number of cubic feet of air space which it is desirable each patient should have. When these facts have been fairly digested by the wealthy and generous of Glasgow the future of the scheme will be no longer doubtful. Meantime, it is to be hoped that the request to be made to Her Majesty for official recognition of the infirmary may meet with a favourable response.

HEALTH OF THE CITY.

The last annual report on the health of the city shows that in the year 1886 there were 13,099 deaths registered, as compared with 13,486 in the previous year, a decrease of 387, representing an average death-rate of 25 in place of 26 per 1000 living. Since the Public Registration Act took effect there has not been so low a death-rate, except in 1879 when it was 24·5 per 1000. The slow but steady improvement which is taking place in the health of Glasgow is indicated in the following table:—

Mean death-rate	1866-75	30·4	per 1000.
" " "	1876-80	26·7	"
" " "	1881-85	26·3	"
" " "	1886	25	"

For the fortnight ending 1st January, 1887, the deaths were 631, giving a death-rate of 31·5 per 1000. Fevers, especially scarlatina and measles, still prevail to a great extent in Glasgow; but it is satisfactory to note that in the whole city there are only 3 cases of typhus, and they are all in hospital. One of the typhus patients is a medical practitioner. It is many years since a Glasgow medical man was attacked by typhus, yet in times not very remote, say twenty years ago, this was a common occurrence, and many valuable lives were thus lost. The value of these fever hospitals, both to the profession and to the community at large could not be more clearly demonstrated than by these facts.

Glasgow, Jan. 18th.

DUBLIN.

(From our own Correspondent.)

THE GENERAL MEDICAL COUNCIL.

I AM in a position to state that Dr. William Moore, Physician in Ordinary to Her Majesty in Ireland, has been offered and has accepted the post of Crown nominee for Ireland on the General Medical Council. Dr. Moore has filled numerous offices with distinction, including that of president of the College of Physicians; and deservedly ranks high in the estimation of the public and his professional brethren.

BRITISH MEDICAL ASSOCIATION.

The tenth annual general meeting of the Dublin Branch of the Association will be held on the 27th inst. in the College of Physicians; when the officers and council for the ensuing year will be elected by ballot, and any other necessary business transacted. The President elect (Dr. Grimshaw), will give the annual address.

BONE-SETTERS: A WARNING.

At a recent meeting of the Drogheda guardians, an application was received from Dr. Adrien for a fee for the performance of an operation under the following circumstances. The patient was a fine young man, aged twenty, who had got his arm broken above the elbow by a fall off a cart. He went to a bone-setter, and as a result of his treatment Drs. Kelly and Byrne were called in, and found the man's arm gangrenous from the tight manner in which the bandages had been applied. On taking off the bandages the bones were found to overlap. The only chance was amputation close to the shoulder, which was done by Drs. Adrien and Kelly. The man is not expected to recover.

BARRINGTON'S HOSPITAL, LIMERICK.

This institution seems financially to be in a very low condition, for at a meeting of the governors last week it was stated that the hospital was £748 in debt, £300 being due to the bank, which had refused to honour any further cheques. It appears also that the resident medical officer and other officers and servants have not been paid their salaries for the past two months. Another meeting of the governors will shortly be held, and in the meantime a committee has been appointed to open a subscription list, and so place the institution in a more satisfactory position than at present.

RICHMOND HOSPITAL, DUBLIN.

There were five candidates for the post of physician to this hospital, which had become vacant by the death of Dr. Lyons. The board appointed Dr. O'Carroll, the assistant-physician. There is no salary attached to the appointment.

ASSISTANT MEDICAL OFFICER TO THE DUBLIN METROPOLITAN POLICE.

By the death of Dr. Long, J.P., a vacancy for an assistant medical officer to the Dublin Police arose; and although the emolument of the post was only £75 a year, yet the competition was most keen, and the candidates were, it is said, over fifty in number, and were from all grades of the profession, from the examiner of a university or corporation down to the simple apothecary. I believe Dr. Long had to compound the medicines ordered, but I understand his successor will not be required to do so. The vacancy has now been filled up by the appointment of Dr. Oulton, formerly resident surgeon to the Meath Hospital.

Dublin, Jan. 18th.

MANCHESTER MEDICAL SOCIETY.—The annual meeting of the members of this Society was held on the 12th inst., Dr. J. Hardie, president, in the chair. The secretary, Mr. F. A. Southam, read the annual report of the committee, in which the members were congratulated on the continued prosperity of the Society. During the past year, it was stated, twenty-four new members had been elected, whilst seventeen had, through death and other causes, severed their connexion. The number of members now on the roll is 249.

ON the 10th inst. an Eye Hospital was formally opened at Cardiff by Mr. Alfred Thomas, M P.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Jan. 17th:

Cranstoun, George, M.B. Durham, Ludlow, Salop.
Middleton, Alfred Hancock, M.D. Dublin, Shankill, co. Dublin.
Moxham, Marcus Camplin, L.S.A., Swansea.
Murray, John, M.B. Dublin, Norfolk-street.
Tattersall, C. Herman, L.R.C.P. Lond., Patricroft, Manchester.
Wild, Charles Henry, L.K.Q.C.P.I., Bedford-road, Bootle.

Admitted on the 18th inst.:—

Adams, Percy Targett, L.S.A., Ashford-road, Maidstone.
Browne, Henry, L.S.A., Cornwall-road, Westbourne-park.
Foxton, Edward, M.D. Kingston, Brockville, Ontario.
Green, Arthur, M.B. Durham, Walker-terrace, Gateshead.
Harrington, Samuel Henry Nazeby, L.K.Q.C.P.I., Parliament-street, Liverpool.
Howitt, John FitzWilliam, M.B. Toronto, Guilford-street.
Johnson, John G., L.R.C.P. Lond., Campbell House, Aldershot.
McLearn, Isaac Crawford, M.D.Q.U.I., Highgate.
Sparrow, John Elliotson Pennington, L.S.A., Clarendon-road, Southsea.
Sumpter, Berners George, M.B. Durham, Cley-next-sea, Norfolk.
Thornton, Fred Whitfield, L.K.Q.C.P.I., Trinity-street, Huddersfield.
Yeoman, William Metcalfe, M.B. Durham, Northallerton.

Admitted on the 19th inst.:—

Blake, William Henry, L.S.A., Brondesbury Villas, Kilburn.
Brown, Henry Herbert, The Park, Harrow.
Crook, Herbert Evelyn, L.R.C.P. Lond., Northfleet, Kent.
Duncan, H., L.R.C.P. Lond., Henrietta-street, Covent-garden.
Spencer, George Herbert, L.K.Q.C.P.I., Turton, Bolton.
Williams, John T. Creswick, L.S.A., Dolgelly, North Wales.

COLLEGE LECTURES.—The annual course of lectures will be commenced on Monday, January 31st, at 4 o'clock, by Professor Francis Warner, M.D., who will deliver three lectures on the "Anatomy of Movement." Professor W. H. Hylson Jessop will deliver three lectures on the "Intraocular Muscles," commencing on Wednesday, February 16th. Professor C. Barrett Lockwood will deliver three lectures on the "Development and Transition of the Testicle, Normal and Abnormal," commencing on Wednesday, February 23rd. Professor A. Alfred Bowlby will deliver three lectures, commencing on Wednesday, March 2nd (subject will be duly announced). Professor Charles Stewart will deliver nine lectures on the "Auditory Organs of the Vertebrata," and on some recent Additions to the Museum, commencing on Wednesday, March 9th. The course will be concluded in June by Dr. Leonard C. Wooldridge, Professor Henry Power, and Professor Christopher Heath. The subjects of the several lectures will be hereafter published. The lectures will be delivered in the theatre of the College on Mondays, Wednesdays, and Fridays, at 4 o'clock punctually each day.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 13th inst., the degree of M.B. was conferred on—

Walsham, Hugo, Caius.

COLLEGE OF PHYSICIANS IN IRELAND.—At the January examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Thomas Spread Campion, William H. Haslop, Hugh Griffith Hughes, Henry John Mathews, Frederick William Monsell, Denis Joseph O'Loghlin, Thomas Fox Parry, John Sclesfield, Thomas Henry Wilson.

MIDWIFERY.—Thomas Spread Campion, Thomas Augustus Connellan, Timothy Corkery, Hugh Griffith Hughes, Wm. Edward MacFeeters, Henry John Mathews, Frederick William Monsell, Denis O'Loghlin, Thomas Fox Parry, Thomas Henry Wilson.

The following have been admitted Members of the College:

J. Armstrong Hanrahan. | William Frazer (Dublin).
William Frazer. | Guy P. L'E. Nugent.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have been admitted Fellows of the College:—

Alfred Asbury, A.M.D. | James McMullen, A.M.D.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on the 13th inst.:—

Bacot, William Rickward, The College, Sudbury, Middlesex.
Ford, Theodore Albert Vores, Beaufort-road, Clifton, Bristol.
Johnson, Reginald Edward, Winter-street, Sheffield.
Wilde, Leonard, Ardwick House, Watford.

UNDERGROUND WIRES.—The Postmaster-General, in reply to a correspondent, states that the question of extending the system of laying telegraph wires underground shall receive his careful consideration.

Digitized by Google

MEDICAL MAGISTRATE.—Dr. Charles B. Plowright has been placed on the Commission of the Peace for the borough of King's Lynn.

A NEW monthly medical journal, entitled *Therapeutische Monatshefte*, edited by Drs. Langgaard and Rabow, is being published by O. Liebreich of Berlin.

THE Marquis of Bute has decided to present to the corporation of Cardiff a site for the proposed hospital for infectious diseases, which it is proposed to provide for that town.

AT the annual meeting of the governors of the Lincoln County Hospital on the 13th inst., it was reported that during the past year the expenditure of the hospital had exceeded its income by £101.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of the fund, held on the 11th instant, Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £61 was distributed among the several applicants.

THE large number of applications for admission to the Normal School of Science and Royal School of Mines at South Kensington at the beginning of the present session has necessitated the adoption of a process of selection for the future.

SOCIETY OF PUBLIC ANALYSTS.—At the annual meeting of this Society held in the rooms of the Chemical Society, Burlington House, on the 12th inst., Mr. A. H. Allen, of Sheffield, analyst for the West Riding of Yorkshire, &c., and author of "Commercial Organic Analysis," was elected President of the Society for the ensuing year.

CARDIFF MEDICAL SOCIETY.—The following members have been elected office-bearers for the year 1887: President: Mr. T. Garrett Horder. Committee: Dr. M. G. Evans, Dr. Herbert Vacher, Mr. J. L. Treharne, and Mr. P. Rhys Griffiths, M.B. Treasurer: Dr. C. E. Hardyman. Hon. Secretary: Dr. W. Campbell.

THE Countess of Dufferin has issued an appeal for subscriptions in aid of the funds of the National Association for supplying Female Medical Aid to the Women of India. The Jubilee year seems, as the Countess of Dufferin remarks, a fitting occasion to make a very special effort to help those Indian women in whose sufferings the Queen has shown so great and personal an interest.

EPIDEMICS OF MEASLES.—Up to the 17th inst., 130 cases of measles, 14 of which proved fatal, were reported by the medical officer to have occurred at Sebastopol, Monmouthshire. In accordance with a notice of the sanitary authority the schools have been closed for three weeks. At Ashford in Kent several deaths have occurred, and the disease is pronounced to be of a very bad type. All the schools in the town have been closed for a fortnight.

PRESENTATIONS.—On the 29th ult. the members of the recent class in connexion with the St. John Ambulance Association at Worsbro' Dale presented Mr. Blackburn of Barnsley, who had acted as their instructor, with a Tantalus spirit stand and a silver jug, in recognition of his services.—On the 13th inst. Mr. E. J. Foulston was presented with an illuminated address and a purse of gold, on the occasion of his departure for Earlestown.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting held on Thursday, Jan. 13th, the following list of officers, council, and microscopical committee was adopted. President: J. B. Nevins, M.D. Vice-Presidents: William Alexander, F.R.C.S.; James Barr, M.D.; Robert Robertson, M.D.; W. Williams, M.D. Treasurer: F. J. Bailey, L.R.C.P. General Secretary: A. Bernard, M.B. Secretary of ordinary meetings: Damer Harrisson, M.R.C.S. Librarian: Richard Williams, M.R.C.S. Council: Alexander Davidson, M.D.; E. T. Davies, M.B.; C. G. Lee, M.R.C.S.; Robert Gee, M.D.; N. K. Marsh, M.R.C.S.; T. G. Wollaston, M.D.; J. D. Crawford, M.D.; Karl Grossmann, L.R.C.P. Edin.; W. Irvine, M.D.; W. P. Rowe, L.R.C.P. Edin.; G. E. Walker, F.R.C.S.; W. Whitford, M.D. Microscopical Committee: W. Alexander, F.R.C.S.; A. Barron, M.B.; P. M. Braidwood, M.D.; Henry Briggs, F.R.C.S.; G. Hamilton, M.R.C.S.; J. S. Hicks, L.R.C.P.; J. R. Logan, M.B.; Rushton Parker, F.R.C.S.; F. T. Paul, F.R.C.S.; W. Williams, M.D.; J. Wiglesworth, M.D. Auditors: William Fleetwood, M.K.Q.C.P.I.; T. G. Wollaston, M.D.

THE third annual ball for the benefit of the Italian Hospital in London was held on the 18th inst., and was largely attended.

MORTALITY OF MEDICAL MEN AT MATANZAS.—The Havana journal, *La Enciclopedia*, states that during the last three years no less than eight medical practitioners have died at Matanzas, which is a port in the northern part of the island of Cuba, the population of which is only about 35,000.

AYR COUNTY HOSPITAL.—The Committee of the County Hospital ball, which was held last week, have been able to hand over to the treasurer of the hospital the handsome sum of £408 17*s* 6*d*, whilst the funds of the charity have been still further enriched to the extent of £40 as the proceeds of the concert given in the Town Hall a few days since

MEASLES IN A LONDON WORKHOUSE INFIRMARY.—A serious epidemic of measles is prevalent in the Homerton district. At the meeting of the Hackney Board of Guardians on the 19th inst., twenty-four cases, four of them proving fatal, were reported to have occurred in the workhouse infirmary. A Board school in the district has been closed to check if possible the spread of the disease.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of the members of this Association, on the 6th inst., a paper was read by Dr. Niven (Oldham) on the Infectiousness of Pneumonia. The author stated that the whole bearing of the inquiry into the question was that the new view that pneumonia was conveyed by germs might lead to the preparation of a vaccine having the power to protect anyone inoculated with it against a subsequent attack of the disease.

MORISON PRIZES FOR MERITORIOUS ATTENDANCE ON THE INSANE.—On the nomination of Dr. Alex. Keiller, LL.D., F.R.C.P.E., the Morison Lecturer on Insanity, the treasurer of the Royal College of Physicians, Edinburgh, has awarded the two annual prizes endowed by the late Sir Alex. Morison for meritorious attendance on the insane to Miss Agnes Shankland, of the Crichton Royal Institution, Dumfries, and Mr. Edward M'Mahon, head attendant, Saughton Hall, Murrayfield.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

FIRST EXAMINATION.

PART I.—CHEMISTRY, INCLUDING CHEMICAL PHYSICS.

Tuesday, January 4th, 1887, from 1 to 4 P.M. (Candidates must answer at least four questions, and not more than six.)

Section I.—1. Explain what is meant by the diffusion of gases. According to what law do gases diffuse? The relative densities of marsh gas and carbonic acid gas being 8 and 22, what are their respective diffusibilities? 2. What is understood by the term latent heat? A pound of ice at 0° C. is placed in a pound of boiling water, and the mean temperature of the water is found to be 10° C. What is the latent heat of water?

Section II.—3. Write a brief sketch of the properties of sulphur. How is sulphuretted hydrogen prepared, and what are its distinguishing chemical characters? Ten grammes of sulphuretted hydrogen are burnt in air. What products, and how much of each by weight, are formed? (S=32; O=16; H=1.) 4. What are the chief properties of iodine? How it it prepared from kelp? State carefully what occurs when iodide of potassium is added to solutions, respectively, of (*a*) mercuric chloride, (*b*) mercurous nitrate, (*c*) lead nitrate, (*d*) silver nitrate, and (*e*) chloride water. Give equations. 5. Describe the oxides, chlorides, and iodides of mercury, and give their formulæ. How are the oxides prepared, and how are they acted on by dilute hydrochloric acid?

Section III.—6. What is the composition of cyanogen, and what are its properties? How can the following bodies be obtained from potassium ferrocyanide: carbon monoxide, cyanide of potassium, prussic acid? 7. What are the relations between marsh gas (methane), chloroform, methylic alcohol, and formic acid? Describe how you would obtain marsh gas from acetate of sodium. Give equations. 8. Describe the constitution of the fats and oils. Some beef fat is boiled with a dilute solution of caustic potash: describe in detail what happens, and the properties of the bodies formed.

[*Note.*—This paper also applies to candidates for the licence of the Royal College of Physicians of London.]

PART II.—MATERIA MEDICA AND PHARMACY.

Wednesday, Jan. 5th, 1887, from 1 to 4 P.M. (Candidates must answer at least four questions.)

1. Give an account of nux vomica, stating its origin, its most important active principles, its medicinal action on the various organs of the body, its official preparations, and their doses. 2. Enumerate the various forms of alcohol contained in the Pharmacopœia. State the strength of each, and give a brief account of their medicinal action.

Digitized by Google

3. What are the official salts of (1) bismuth, (2) zinc? In what doses are they employed, and what are their actions? 4. Give an account of the medicinal action of hyoscyamus. To what drugs is it most closely allied, and to what is it antagonistic? What are its preparations, and what are their doses for internal administration? 5. Give the composition of the following Pharmacopœial preparations:—Mistura ferri composita, pulvis cretæ aromaticus cum opio, pulvis catechu compositus, lotio hydrargyri flava, pulvis opii compositus, liquor arsenii et hydrargyri iodidi. 6. What forms of sulphur are mentioned in the Pharmacopœia? What are its preparations and doses and how is it eliminated?

[*Note.*—This paper also applies to candidates for the licence of the Royal College of Physicians of London.]

PART III.—ELEMENTARY PHYSIOLOGY.

Tuesday, January 4th, 1887. From 10 A.M. to 12 noon. (Candidates must answer at least four of the six questions.)

1. Name the tissues shown under microscopes A, B, C. By what characteristics do you recognise them? 2. Give the position and action of the valves of the heart. 3. Milk is a complete food for infants. Explain this statement. 4. Describe and explain a simple reflex act. 5. Enumerate the chief constituents of bile. 6. What changes does a striped muscle undergo in contraction and in death.

SECOND EXAMINATION.

PHYSIOLOGY.

Thursday, January 6th, 1887, from 2 to 5 P.M. (Candidates must answer at least four questions.)

1. Explain and illustrate the action of the nervous system on the arteries. 2. Describe the minute structure of the spinal cord. 3. What is the structure of a capillary bloodvessel and a venule? Contrast the character of the blood-flow in these with that in an arteriole. 4. Describe the structure and functions of the skin. 5. Mention the fats which are usually taken as food. How are they digested? What is their probable destination? 6. State the composition and properties of glycogen? Where does it occur? How may it be prepared?

ANATOMY.

Friday, January 7th, 1887, from 2 to 5 P.M. (Candidates must answer at least four questions.)

1. Describe the sensory nerve-supply to the skin of the face and scalp. 2. Describe the dissection required to expose the deep epigastric artery. 3. Give the origin, course, insertion, actions, relations, and nerve-supply of the pyriformis muscle. 4. Describe the œsophagus, and give its situation, relations, arterial and nervous supply. 5. Enumerate the muscles acting on the shoulder-joint. Give their actions and nerve-supply. 6. Give the course, relations, and tributaries of the superficial and common femoral veins.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

SOUVERIE, F. P. MCDONALD, M.D., C.M., &c., has been appointed Medical Officer and Public Vaccinator for the North District of Wallasey of the Birkenhead Union.

BRIGGS, HENRY, M.B., F.R.C.S., has been appointed Honorary Medical Officer to the Hospital for Women, Shaw-street, Liverpool, vice Lupton, deceased.

BURKITT, JOHN C. S., M.D., L.Ch. Roy. Univ. Irel., has been appointed Medical Officer to the Whitwick Local Board.

CASTLE, HUTTON, M.B. Lond., M.R.C.S., has been appointed Medical Officer for the Shorwell North District of the Isle of Wight Union.

COURTIER, RAYMOND, M.B.Dur., M.R.C.S., late Senior House-Physician at the Westminster Hospital, has been appointed Assistant Medical Officer to the St. Marylebone Infirmary, Notting-hill, W.

DE JONG, EDWARD M., B.A., L.S.A., has been appointed Resident Junior Visiting Surgeon to the Ancoats Hospital, vice Alfred Mackay, M.B., C.M., resigned.

DRAKE, THOMAS, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the West Ham Urban Sanitary District.

GREENLEES, T. DUNCAN, M.B.Edin., Second Assistant Medical Officer to the Counties Asylum, Carlisle, has been appointed Assistant Medical Officer to the City of London Asylum, Stone, Dartford.

HOBBES, T. G. FOSBROKE RICE, L.F.P.S., L.M., L.S.A., has been appointed Medical Officer and Public Vaccinator to the Sutton District of the Aston Union, vice C. Barlow, M.R.C.S., L.S.A., deceased.

INGLEBY-MACKENZIE, K. W., M.R.C.S., L.R.C.P. Lond., has been appointed House-Surgeon to the Royal Isle of Wight Infirmary, Ryde, vice A. G. R. Foulerton, M.R.C.S., L.R.C.P., resigned.

JOLLIFFE, WALTER J., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Shorwell South District of the Isle of Wight Union.

LIMRICK, W. SOMERVILLE, L.R.C.S., L.R.C.P.Ed., has been reappointed Medical Officer of Health by the Waterloo Local Board.

PARRY-JONES, W. R., L.R.C.S., L.R.C.P.Ed., L.S.A., has been appointed Medical Officer to the Rhosddu Lodge, N. U. Order of Oddfellows, the Bridge House, Golden Lion, Bowling-green, and Wrexham and District Colliers Tontine Societies.

RYGATE, JOHN R., L.K.Q.C.P.I., L.R.C.S.Ed., has been appointed Medical Officer for the Seventh District of the Bridgwater Union.

WESTON, GEORGE H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Polesworth District of the Atherstone Union.

WHITFORD, WILLIAM, M.D., Honorary Assistant Physician, has been appointed Physician to the Stanley Hospital, Liverpool, vice D. D. Costine, M.D., J.P., appointed Consulting Physician.

YOUNG, R. R., M.B., C.M.Glas., has been appointed to the Medical Staff of the Midland Railway Company, Leicester Centre.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CARLISLE COUNTY ASYLUM.—Junior Medical Assistant. Age under twenty-six. Salary £90, with board; no wine or beer.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N. — Two Clinical Assistants.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Clinical Assistants.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Regent's-park. — Assistant Physician.

HULL AND SCULCOATES DISPENSARY.—House-Surgeon. Salary £150 per annum, with house (unfurnished), coals, and gas.

LANCASHIRE COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer. Salary commences at £100 a year, with apartments and board.

NATIONAL ORTHOPÆDIC HOSPITAL FOR THE DEFORMED, Great Portland-street.—Surgical Registrar and Anæsthetist. An annual honorarium of £30 is attached to the office.

NORTH RIDING INFIRMARY, Middlesborough-on-Tees.—House-Surgeon. Salary £100 a year, with bed, board, washing, and £5 per annum in lieu of beer.

ROYAL BERKS HOSPITAL, Reading.—Assistant House-Surgeon. Qualification not essential. Board and lodging, but no salary.

SANITARY ASSURANCE ASSOCIATION.—Chief Medical Officer.

Births, Marriages, and Deaths.

BIRTHS.

HERMAN.—On the 19th inst., the wife of G. Ernest Herman, M.B., F.R.C.P., of Harley-street, Cavendish-square, W., of a son.

HUXLEY.—On the 17th inst., at Higher-terrace, Torquay, the wife of J. Usher Huxley, M.D., of a daughter.

JONES.—On the 12th inst., at Llanfyllin, Montgomeryshire, the wife of F. Felix Jones, M.R.C.S. &c., of a daughter.

MACQUEEN.—On the 16th inst., at Eastbourne, the wife of Thomas MacQueen, M.B., C.M., of a son.

MAURICE.—On the 15th inst., at Terrace House, Marlborough, the wife of J. Blake Maurice, M.D., F.R.C.S., of a son.

MARRIAGES.

GRIFFITHS — COLLING. — On the 15th inst., at St. Michael's, Great Torrington, Surgeon Gilbert Saunders Griffiths, 32nd Punjab Pioneers, to Katherine Celestina, second daughter of the late H. R. Colling, Esq., of Oakehampton, Devon.

HODGE—GEDYE.—On the 14th inst., at the Wesleyan Chapel, Cotham, Bristol, the Rev. Sydney Rupert Hodge, M.R.C.S., L.R.C.P., to Ann Elizabeth, eldest daughter of Francis W. Gedye, of Ashley Grange, Bristol.

LEEDS—EDWARDS.—On the 15th inst., at St. Andrew's, Holborn, Thos. Leeds, M.R.C.S., to Fannie, daughter of Joseph Edwards, of Burton-on-Trent.

REID—HORNE.—On the 5th inst., at the Parish Church, Kirkcudbright, William Swanston Spence Reid, M.B., C.M., to Agnes Darling, daughter of the late James Darling Horne.

RISK — LANGSTON-FADDY. — On the 13th ult., at St. Luke's Church, Jullandur, Punjab, Surgeon E. J. Erskine Risk, A.M. Staff, to Ellie Mary, youngest daughter of Major Langston-Faddy, Ret. List, Bengal Army.

STANWELL — SHARPE. — On the 12th inst., at St. Mary's, Rochdale, William Stanwell, M.R.C.S., to Mabel Frances, eldest daughter of the late Alex. Barclay Sharpe, M.D., F.R.C.S., of Norwood, Surrey.

WARNER—GROVE.—On Wednesday, the 19th inst., at St. Peter's, Eaton-square, by the Rev. R. E. Warner, M.A., cousin of the bridegroom, assisted by the Rev. A. Boyd, M.A., Frederick Ashton Warner, L.R.C.P., M.R.C.S., L.S.A.Lond., only surviving son of Frederick Warner, Barrister-at-law, of Woodford House, Trinidad, W.I., to Sydney Anne Grove, daughter of the late Christopher Grove, of Hertfordshire House, Bucks.

DEATHS.

ANGIER.—On the 16th inst., at his residence, The Highlands, College-road, Upper Norwood, James Hague Angier, M.R.C.S., L.S.A., in his 84th year.

ANDREW.—On the 10th inst., at his residence, St. John's Hill, Shrewsbury, Edwyn Andrew, M.D., aged 55.

HOLLIS.—On the 17th inst., at Deacons, Yarmouth, Isle of Wight, Charles Wise Hollis, M.D. Univ. Edin., in his 71st year.

NOTT.—On the 17th inst., at Russell-road, Kensington, Hamlin Nott, M.R.C.S., L.R.C.P.Ed., Surgeon-Major, Retired List, H.M.'s Indian Forces.

SNAPE. — On the 13th inst., at Chorley New-road, Bolton-le-Moors, Richard Forth Snape, F.R.C.S.Eng., aged 65.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 24.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Dr. J. L. W. Thudichum: The Diseases of Plants, with special regard to Agriculture and Forestry (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Mr. Davies-Colley: Case of Plastic Operation for Ectropium.—Mr. Walter Pye: Case of Plastic Operation on the Face.—Dr. Maguire: Analgesia after Injury to the Head.—Dr. Isambard Owen: Case of Tumour of Abdomen, and others.

Tuesday, January 25.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department. Mondays and Thursdays, 9.30 A.M.
SOCIETY OF ARTS.—8 P.M. Mr. J. H. Kerry Nicholls: The Volcanic Eruption in New Zealand.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Barwell: On Widely Incising by a Two-Stage Method Hydatids of the Liver.—Mr. W. E. Cant: Clinical Observations on "Induration" in the Primary Lesion of Syphilis in Women (communicated by Mr. Holmes).

Wednesday, January 26.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
HUNTERIAN SOCIETY.—8 P.M. Mr. Croft will explain and demonstrate the Method of Treating Fractures by the Immediate Application of Plaster-of-Paris.
SOCIETY OF ARTS.—8 P.M. Mr. J. Traill Taylor: Photographic Lenses.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown. Address on Listerism, by Dr. Granville Bantock. Council at 8 P.M.

Thursday, January 27.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Living and Card Specimens at 8 P.M.:—Mr. Nettleship: (1) Atrophy of Optic Nerves with Multiple Congenital Exostoses of Skull; (2) Three cases of Night Blindness with Peculiar Retinal Changes.—Mr. George Cowell: Three cases showing the result of Operation for Conical Cornea.—Mr. Marcus Gunn: Case of Transverse Calcareous Film of Cornea. Papers:—Mr. P. H. Mules: A short record of Some Unusual Clinical Cases.—Mr. G. A. Berry: On three cases of Acute Cerebral Disease with Ocular Symptoms.—Mr. W. H. Jessop: Sudden and Lasting Lateral Nystagmus.—Mr. W. Lang: Case of Meningitis after Excision.

Friday, January 28.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Address by the President. Mr. Henry Morris: (1) A case of Calculous Disease of both Kidneys, with Remarks on the Surgical Treatment of Calculous Kidneys; (2) A case of Nephro-lithotomy.—Mr. Howard Marsh: A case in which very Severe Symptoms were due to Four Small Stones in an Atrophied and Movable Kidney; Failure to Detect the Kidney by Lumbar Incision; Discovery by Laparotomy; Successful Removal of the Organ.—Mr. W. H. Bennett: A case of Supposed Nephrotomy for Scrofulous Disease. Living Specimens:—Mr. J. R. Lunn: (1) A Boy with Ichthyosis; (2) Peculiar Deformity of the Feet in an Ataxic Patient; (3) A Man with Raynaud's Disease of the Feet; (4) A case of Myxœdema with want of Development of the Genital Organs.

Saturday, January 29.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

Captain Petrie.—The disclosures made by our Analytical Sanitary Commission resulted, we are happy to say, in such legislative measures being adopted as have rendered impossible in this country gross adulterations of the kind specified in the extract from the Pittsburgh paper. The article, as a whole, is probably intended to be amusing, rather than descriptive of an actual condition of things.

A Subscriber will find the reply in our issue of the 8th inst., p. 109.

COCAINE IN WHOOPING-COUGH.

To the Editors of THE LANCET.

SIRS,—In a letter which appeared in THE LANCET of Feb. 27th, 1886, on the treatment of pertussis by local applications, I suggested that cocaine be tried with the view of lessening the severity of the paroxysms. In the Journal of the American Medical Association of October 9th, there appears an original article by Dr. A. V. P. Garnett of Washington, in which he states that in January of last year he determined to try the use of hydrochlorate of cocaine by inhalation and used a six per cent. solution of muriate of cocaine in chloroform, of which ten minims poured into a wineglass made warm by tepid water were placed under the patient's mouth. No difficulty was experienced after a few trials in getting the patient to inhale the vapour. This practice was repeated every four hours, and, whenever possible to do so, immediately preceding or at the outset of a paroxysm of coughing, in the latter instance using double the dose of the solution. He found that by this means many of the paroxysms were arrested entirely or materially cut short. In very young children Dr. Garnett has found it more convenient to pour ten or twelve drops on a handkerchief, instead of using an inhaler. Should further experience confirm these conclusions, we have in cocaine a remedy that will do much to rob this disease of its most distressing symptoms, besides greatly facilitating the application of germicides for its radical cure. I am, Sirs, yours truly,

Bournemouth, Jan. 17th, 1887. A. WOODMAN DOWDING, M.D.

M.D. & F.R.C.S.E. and *O.P.Q.* have not enclosed their cards.

Mr. Gillibrand.—Next week.

SHOULD NORFOLK HOSPITAL BE FREE?

Mr. James C. Barnham, in a letter to the *Eastern Daily Press*, argues against the proposal of making admission to the hospital independent of letters of subscribers and dependent on the mere comparative fitness of cases as determined by medical officers and others. He thinks such a rule would tell hardly upon patients coming from a distance, who might find themselves refused, and that it would not conciliate the support of distant parishes.

A Young Practitioner.—The attention of the bodies whose qualifications the advertiser holds should be directed to the matter.

Señor Fontanal (Lerida).—We cannot exchange.

Mr. J. W. Mason's (Hull) letter arrived too late for publication this week.

PERSISTENT DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—In reply to the request of "L.R.C.P." for information from your readers concerning the treatment of persistent diarrhœa, I beg to send you the following abstracts of two cases.

CASE 1.—A coachman, aged forty-two, consulted me in 1879 for persistent diarrhœa. He had been exposed to great hardships and privations during the Franco-German War, and had had intermittent fever. Whenever he took anything to drink it was sure to "run through him" immediately, and he had been obliged to give up his place because he found that he was unable to sit for any length of time on the box without being disturbed by his infirmity. On the theory that the trouble might be of malarial origin, I gave him quinine (all the more usual remedies having been tried by my predecessors), and this was the last I saw of him as a patient. A few months later, however, I met him in the street, and in reply to my inquiry as to his health, he informed me that he was perfectly well. I was just congratulating myself on the success of the treatment when he added that it was not due to any physic of mine, or, indeed, of any professional brother, but that one of his colleagues who had suffered in a similar way had cured himself by wearing a flannel binder round the body, and, following his friend's advice, he had found it equally efficacious.

CASE 2.—A lady of uncertain age, from Central America, gave me some particulars about a similar condition. I was attending her husband, and the ailment was mentioned as a chronic infirmity, for which she did not expect to find any relief. She was saturated with malaria, and had tried every kind of treatment, the only medicine in which she had retained any faith being hamamelis. I do not think I offered any advice; but in any case she would not have followed it. The following year she again visited Paris, and I was much struck with the change for the better in her appearance, and learnt that she was then quite well. After trying without effect a grape cure and a whey cure in Switzerland, she had been recommended to go to Wiesbaden, where she had by the use of the waters been restored to health, and witnessed a like success in the case of a fellow bather.

I presume that your correspondent has eliminated from his diagnosis the possibility of organic disease of the liver. Assuming, then, that there is only habitual hyperæmia of liver and intestine, associated with malarial poisoning, I would recommend him to abstain from fluids during meals and the period of digestion, and take, even if it has failed under other circumstances, small doses of arsenic.

I am, Sirs, yours faithfully,

Rue Marbeuf, Paris, Jan. 17th, 1887. OSCAR JENNINGS, M.D.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "L.R.C.P.," seems to me to be suffering from the result of abnormal fermentative changes in the bowels, due probably to the original obstruction. In all ordinary diarrhœa cases I find carbolic acid with ammonia sufficient to check these changes and the resulting flatulence. When, however, an element of chronicity is introduced, the bacillary consequences have to be combated with germicidal remedies having a more remote action, and of these the biniodide of mercury is the one I depend upon. I would prescribe as follows:—℞. Spiritus ammon. aromat., ʒss.; sol. morph. hydrochlor. (P.B.), ʒi.; sol. acid. carbolic. (1 in 20), ʒvi.; ether. chloric., ʒii.; sol. hydrarg. bichlor. (B.P.), ʒi; potass. iodid., ʒss.; aquam ad ʒviii. M. ft. Mist. One tablespoonful every four hours.

I am, Sirs, your obedient servant,

Jan. 17th, 1887. C. R. ILLINGWORTH, M.D.

To the Editors of THE LANCET.

SIRS,—I have little doubt in my own mind that "L.R.C.P." is suffering from malarial poisoning, and I would suggest a trial of large doses of quinine. I have myself suffered from such diarrhœa on my return from the tropics, and at first could not account for it, and treated it wrongly with astringents; but experience has proved to me that, as far as my case went, its cause was tropical malaria lying latent in my system and breaking out periodically in troublesome diarrhœa, and at other times in excruciating muscular pains. As Sir J. Fayrer said in his lectures at the College of Physicians in 1882, its symptoms are multifarious. Among other peculiar pains it gives rise to is unendurable pain in the vicinity of the kidney and along the course of the ureter and into the testis. This in my case is always relieved by a large dose of quinine. I remember in my young and inexperienced days, in the hot weather in India, treating this latter expression of its existence in soldiers as acid urine passing down the ureter, and giving bicarbonate of potash and anodynes. Since I have become the subject of such symptoms I am forcibly reminded of my malpraxis, and in those cases a large dose of quinine would have given rapid, if not instant, relief.—I am, Sirs, yours faithfully,

Jan. 17th, 1887. A SURGEON.

To the Editors of THE LANCET.

SIRS,—Will anyone kindly give me some suggestions as to the treatment of the following case of obstinate diarrhœa?

Mrs. L——, after suckling her first child for two months, was attacked for the first time in her life with diarrhœa, which has continued, more or less, for the last five years. Milk, vegetables, fruit, or coffee always bring it on. Worry, anxiety, and excitement also have the same effect. The diarrhœa came on worse after the birth of the second child and the third, so that she had to give up suckling. She is rather weak, and not well nourished. Appetite good. A mixture of catechu, opium, and chloric ether seems to have given more relief than any other medicine. She is the wife of a medical man, and has undergone a variety of treatment without any permanent good effect.

I am, Sirs, your obedient servant,

Jan. 17th, 1887. NEMO.

Dr. W. H. Murray.—We fear the employer is not liable, unless our correspondent can prove that he was called in on the employer's authority.

Mr. Eversbed (Arundel).—We shall be glad to receive the particulars.

R. S. W.—It is customary to waive all considerations of fee in such cases.

HOMŒOPATHY.

To the Editors of THE LANCET.

SIRS,—I have just received a pamphlet on "The Medical Treatment of our Time," which proves to be a prize essay on homœopathy addressed apparently more to the public than to the profession. In the appendix there is an urgent appeal to young practitioners to "visit the homœopathic hospital in Great Ormond-street, watch its treatment, examine into its cases, and test its results with an open and candid mind and a sincere desire to arrive at truth." Now, this is exactly what I did, or rather attempted to do, soon after I was qualified. I was treated with great courtesy by the medical officers, and allowed to accompany the physicians on their somewhat rapid rounds; but upon my repeated requests to be permitted to attend in the morning and assist in taking notes and examining the patients, I was told that that could not possibly be allowed. I was, I remember, shown a patient who was being cured of impetigo by taking a solution (!) of carbon, and was assured that some drug—I forget what—had caused several ovarian tumours to disappear. I was also taken to a meeting of the British Homœopathic Society, where I heard it gravely stated that natrium muriaticum (chloride of sodium) in minute doses was the best treatment for relapsing fever. I was also shown the book by which, as I was told, all homœopaths studied their treatment, referring to it as to a dictionary. This was "Jahr's Materia Medica." The absurdities I found in it when I looked at it in the British Museum convinced me that homœopaths must be satisfied with very little evidence, and has since made me sceptical when I am told of the wonderful cures they effect.

I am, Sirs, yours faithfully,

Jan. 18th, 1887. A BAFFLED INQUIRER.

*** We have also received a letter on this subject from Mr. A. G. Bateman, M.B., in which he says that Drs. Ringer and Brunton have done an immense deal to break down the barrier between homœopathy and allopathy, asks for a calmer and juster examination of both systems and, with a generosity which does him no discredit, argues for a discontinuance of what he calls "boycotting" the homœopath. The prize essay which calls forth these letters is prefaced by a communication from Dr. Richard Hughes, in which, in a somewhat menacing tone, he says, and he reiterates, that "this [the prize essay] may be the last appeal to the profession of this country for justice to homœopathy." We regret to say that the "last appeal to the profession" looks much more like an appeal to the public, or rather to the less informed among the public. The medicine of to-day, excepting homœopathy, is held up to ridicule and disparagement, and is in very material respects misrepresented whilst its real achievements are not stated. The whole idea underlying the prize essay is that there is a conspiracy in the minds of the men of medical science to shut their eyes to the discovery of Hahnemann. This is an admission of despair and almost of failure. Is there any other instance of all the scientific men in Europe resisting a true discovery for nearly a hundred years? The idea is altogether absurd. The sooner homœopaths see that they boycott themselves the better for them. All they have to do is to drop their distinctive appellation, cease to believe that there is something in the human mind specially inimical to them, liberate their own minds from the fetters of a fantastic notion which they are pleased to call a "law," and recognise the general drift of medical science and art, and they will find no unfriendly feeling to them.—ED. L.

Nivis.—Such a person is not likely to suffer prosecution. But he is not justified in acting in the way suggested.

Frater.—It is difficult to answer the question without knowing the nature and amount of the insurance for which the fee is paid.

Mr. E. J. Fisher.—The duty is by law made imperative and gratuitous.

CITY AND GUILDS OF LONDON INSTITUTE.

PROFESSOR ARMSTRONG'S lectures at this institution, on the Chemistry of the Alkaloids and Albuminoids, commence on Monday next, Jan. 24th, and not on the 27th, as by an error was stated in an advertisement in our columns.

M.D., F.R.C.S.—Our correspondent acted with much humanity and reasonableness. The journey home might have been followed with fatal consequences. He has the satisfaction of having done right—the praise of Boards of Guardians does not always follow that line of conduct. The existence of measles already in the infirmary nullifies the only conceivable argument against his action.

Constant Reader.—1. Moorfields or any of the principal general hospitals.—2. This is more a question of taste than of professional etiquette.—3. We cannot give an opinion without seeing the circular.—4. As we understand the question, the reply must be in the affirmative.

Honorarium.—Unless any circumstances exist of an exceptional nature, such as length of attendance, &c., the charges mentioned appear highly reasonable.

EMASCULATION OF FOWLS.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "B. L. T.," will find all he wants relative to caponising and poulardising of fowls if he refers to the large edition of Tegetmeier's Poultry Book, p. 138 (published by Routledge).

As I am writing, I should like to take the opportunity of asking whether any of your readers have found any special treatment succeed in split or fissured lip. A little girl, aged ten, always suffers from this in cold weather, especially the lower lip, which gets rather a deep crack in the centre. Even if it slightly heals, laughing will make it bad again. I have tried several of the usual applications—oleates, salves, &c.

I am, Sirs, yours faithfully,

Jan. 19th, 1887. FIDELIS.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "B. L. T.," we beg to say we have been making sets of instruments for caponing chickens for upwards of eight years. Directions as to the mode of operation accompany each set. We are, Sirs, yours obediently,

Jan. 18th, 1887. KROHNE AND SESEMANN.

Mr. Brown (Oban).—We have not given an exhaustive opinion on the nutritive value of the esculent. One of the Handbooks published by Clowes in connexion with the late Health Exhibition, entitled "Health in Diet," Part I., contains a chapter on the subject, which may possibly answer the purpose of our correspondent.

THE LICENCE OF THE LONDON COLLEGE OF PHYSICIANS A SURGICAL QUALIFICATION.

To the Editors of THE LANCET.

SIRS,—Can a L.R.C.P. Lond. call himself "Surgeon," having no other diploma? Or is a L.R.C.P. Lond. having only that diploma a surgeon? Can he give surgical evidence in court? Can he sue in a county court for surgical treatment? I am, Sirs, yours truly,

January, 1887. L.R.C.P. LOND.

*** The answer to all the above questions is in the affirmative. The licence of the London College is a double qualification, complete in itself.—ED. L.

ERRATUM.—An obvious printer's error occurred in our issue of Dec. 25th, second paragraph, page 1245, where "Birmingham" is put for *Washington*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Fenwick, London; Dr. Charteris, Glasgow; Dr. Quinlan, Dublin; Dr. Griffiths, London; Dr. Maclagan, London; Mr. Harwood, Bristol; Sir Philip Magnus, London; Rev. C. Bullock, Blackheath; Mr. Symonds, London; Mr. Fisher, Wolverhampton; Dr. Illingworth, Clayton; Mr. Shirley Deakin; Dr. Alderson, London; Mr. E. C. Beale, London; Dr. Percy Boulton, London; Mr. J. Harveian Lectures
ON
CANCER OF THE UTERUS.

By J. WILLIAMS, M.D. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE II.
CANCER OF THE CERVIX.

(*Concluded from page 163.*)

CASE 15.—A married woman, thirty-one years of age, was admitted into University College Hospital in December, 1884 and gave the following history. She first noticed a yellow discharge three years ago, which has greatly increased in quantity during the last three months. It was preceded by bearing-down pain. During the last three months she has had hæmorrhage about a fortnight after each menstrual epoch, lasting for about two hours. This was first noticed after a fall. She began to menstruate in her fifteenth year, has always been regular, with bearing-down pain for two or three hours. She has been losing flesh for twelve months, but more rapidly during the last five months, and during this time she has suffered from indigestion, swelling of the feet, and faintness at times, once causing her to fall and hurt her back. She has had rheumatic fever three times. She has been twice married, the first time at eighteen; she became a widow at twenty, and was married again at twenty-nine. She has had one child by the first husband, and no miscarriages. She was fairly nourished, somewhat sallow; she weighed 7 st. 7 lb.

The uterus was moderately low down, slightly retroverted, and freely movable; the cervix had been lacerated on the right and left sides. The anterior lip was rough, and there was a rough edge apparently at the junction of the vaginal surface with that of the canal. The posterior lip was thickened, soft, everted, and bled readily on examination. The surface of the growth was of a pale pink colour, and somewhat like brain-substance in appearance. The growth in the posterior lip extended backwards, but did not involve the vagina.

The cervix was amputated above the vaginal insertion. After removal the nodule on the posterior lip was found to be three-fourths of an inch in diameter. On the anterior was a papillary superficial growth about three-fourths of an inch in diameter and one-fourth of an inch in depth. The surface appeared rough, and the stratified epithelium was retained to the border of the disease on both lips, and at that point was a slight depression as if it ceased abruptly. On the vaginal surface of the nodule on the posterior lip the stratified epithelium was intact. The squamous epithelium on the vaginal portion was preserved. The whole thickness of the posterior lip was cancerous; the cancer extended downwards so as to abut on the squamous epithelium. It was of the columnar type, and developed in the glands. It appeared to have begun in the deeper parts of the glands.

She returned twelve months afterwards with recurrence, and I ask your particular attention to what I have to say about this, for its importance from a clinical and therapeutical point of view cannot be exaggerated. A portion of the vagina and of the stump of the uterus remaining after the first operation was removed, and when the part removed was submitted to examination a very curious and interesting condition was found. The surface of the vagina as well as of its walls was healthy. The epithelium was somewhat thickened, but it showed no sign of malignancy. The surface of the stump was healthy. There were numerous glands in the mucous lining of the portion of the canal left, and these were healthy; none of them showed signs of cancer. Deep in the cervical wall, however, on its outer aspect, was found well-developed cancer. Between the glands on the inner surface of the canal and the diseased tissue was a layer of perfectly healthy cervical tissue, containing neither glands nor cancer. There was no connexion between the glands present in the cervix and the malignant new growth. The cancer was of a typically glandular character, and every stage of transition from almost healthy glands to cancerous masses could be distinctly traced. Whence came the disease? The recurrent disease presents the same glandular character as the primary disease in the cervix, and yet it does not grow from the cervical glands. On examining the whole section, we find the cancer grows from the outer end of the cicatrix upwards and inwards into the wall of the cervix; and it is clear that before the first operation the disease had extended through the whole thickness of the cervix and invaded the cellular tissue around, though in so slight a degree as not to have affected the mobility of the uterus, and to have escaped notice during the operation. As far as the uterine stump was concerned the cancer had been extirpated, but the cellular tissue around proved traitorous and the disease recurred on the outer and non-glandulous side of the organ. I must illustrate this further by another case of no less interest.

CASE 16.—A married woman, very sallow and cachectic-looking, was admitted on May 9th, 1885. She weighed 8 st. 3 lb. For the last six months she has been getting thinner; she has noticed a slight discharge, and has lost a great deal of blood: during the whole time she has hardly been free from hæmorrhage. She has had slight pain in the stomach and between the shoulders. She has frequent frontal headache, and lately has frequently vomited after taking food. She has no pain or flatulence after food. Temper bad. She was married when nineteen years of age, and has had five children, at twenty, twenty-one, twenty-three, twenty-five, and twenty-seven years of age. Her labours were good. The catamenia appeared at thirteen, and have always been regular until a few months ago, lasting six days without pain. The cervix was low down, freely movable, and of the diameter of half a crown. It was flattened and granular, some of the granules being hard, others soft. The cervix was greatly thickened. The body was not large for a woman who had had five children; it was freely movable.

Supra-vaginal amputation of the cervix was done, and in the course of the operation the disease was found to extend up higher than was expected, the whole of the cervix being thickened. The cervix and the greater part of the body was removed, and the mucous membrane of the fundus, together with that at the orifices of the Fallopian tubes, were shaved off. The cancer in this instance proved to be histologically of the same character as that already described—glandular. The patient was lost sight of until August last, when she came back complaining of a return of the bleeding. On examination it was found that recurrence of the disease had taken place, and the manner of it and the lines of its growth were very clear, and have an important bearing upon the operative treatment of cancer of the cervix.

The patient was readmitted into the hospital on Aug. 31st, 1886, sixteen months after the operation. She said that she had been well until lately, when bleeding returned, and recurred occasionally, lasting four or five days. She had a varying amount of offensive discharge, but always small in quantity. The mucous membrane of the vagina was healthy up to the old wound. A finger was passed through the opening at the top of the vagina into a cavity large enough to hold a small walnut. The sides of this cavity were formed by the cellular tissue around the cervix, and the bases of the broad ligaments, the bladder and peritoneum, and the roof, by the remains of the body and fundus of the uterus left after the operation. The sides of this cavity were cancerous. The walls of the vagina were fixed and rigid—the anterior in almost its whole length, the posterior for about an inch from the top; the sides were also similarly affected. On microscopic examination of a portion of the vagina at the edge of the wound, the superficial epithelium was found intact, and the papillæ were not enlarged; beneath the epithelium was a layer of healthy vaginal wall, and deeper still was cancerous tissue. The recurrence was of a cylindrical shape, but the cells composing it might have been taken for those arising from squamous epithelium rather than from columnar. While in the hospital she had several attacks of severe hæmorrhage, and died on September 20th.

On examination after death the peritoneum of the pelvis was in the main healthy. The fundus of the uterus was normal. It was freely movable within certain limits, the limits being determined by the indurated tissues below the stump at the upper end of the vagina. There was a chain of cancerous glands running up along the iliac vessels on

Digitized by Google

the left side; on the right side were a few enlarged glands at the brim of the pelvis, at the sacro-iliac synchondrosis, and along each side of the spine. There were three yellowish white spots, each of the size of a hemp-seed, on the posterior aspect of the fundus. They were covered by peritoneum, and the vessels running into them were injected. The ovaries were healthy. The right Fallopian tube was closed at the outer extremity, but not dilated; the left was healthy, but a little more bent than usual owing to an old adhesion. The rectum and sacro-uterine ligaments were healthy. There was a large opening between the bladder and the vagina. The new growth had spread for the most part in the cellular tissue around the vagina, breaking through the mucous membrane in a few places only. The tissue between the vagina and the bladder was involved as far down as the opening of the urethra; posteriorly the disease extended for a much shorter distance. The growth was sloughing. The mucous membrane of the vagina was healthy, except at a few points where a few whitish spots as big as carraway-seeds were seen, caused by the encroachment of the new growth from the surrounding tissues. The kidneys showed extreme interstitial nephritis; the pelves were dilated; the right contained pus; there was commencing suppurative nephritis in the right kidney.

In this instance the recurrence took place, not in the uterine stump or in the vagina, but in the peri-cervical cellular tissue. It grew into the bladder, forming a large opening into it, and into the cellular tissue at the base of the broad ligaments and around the vagina, and at the time of death had only just begun to invade the uterine stump and the vaginal mucous membrane by extension.

Three other cases I have observed in which the cervix was amputated for cancer and in which recurrence took place. In two of these the disease did not return in the stump, but in the cellular tissue around, and it did not appear in the stump until the close; in one I cannot tell whether the recurrence appeared in the stump or cellular tissue. In one of those in which recurrence showed itself in the cellular tissue, I do not know the nature of the cancer; in the two others it began in the glands.

But cancer may also begin not only in the lower section of the cervix, but also just below the inner orifice in the substance of the cervical wall. This happens perhaps oftener than is generally supposed, and the fact has not been taken into consideration in theorising about the cause of cancer. I have seen two instances of this which were observed from an early period.

CASE 17.—The first was that of a lady, aged about forty years, of a very fair complexion, who had had two children and some miscarriages. I saw her first in July, 1878. She said that she had not been poorly for six weeks, and that she felt sick and had very frequent micturition. On examination, the os was found large and patulous; and high up, close to the inner orifice in the wall of the cervix, was a small hard mass the size of a pea. This was thought to be a small fibroid. I saw her again in 1879. She said that she had had a miscarriage at Christmas-time. Her husband had been away for six months, and returned a fortnight ago, and she had observed a slight loss of blood after coitus since, but at no other time. She had no pain and no discharge. The uterus was a little enlarged and freely movable. The posterior wall was thickened, and on its inner surface was a small ulcer about the size of a shilling, which extended slightly on the vaginal surface of the lip; it was depressed with hard edges, and it bled on the slightest touch. The uterus was extirpated. It was three inches and a half in length. The walls of the body were somewhat thickened, but otherwise appeared to be healthy. The cervix was considerably enlarged, the enlargement affecting chiefly the posterior wall, which had a small ulcer situated on its anterior surface just within the os. The anterior lip was papillary on the surface. Section showed the posterior wall to be occupied by a mass of the size of the kernel of a walnut. This reached upwards to a little above the level of the internal orifice, and occupied the whole thickness of the wall, and it reached downwards to the portio vaginalis; but it had nowhere penetrated through the mucous membrane of the portio, which remained intact. The mucous membrane of the lower half of the cervical canal had broken down, and there was found the ulcer I have already mentioned. The growth appeared to the naked eye almost as if it were encapsuled; but this appearance seemed to be due to the pressure exercised by the growth upon the parts immediately surrounding it. The growth was a glandular cancer.

But cancer may have more than one point of origin. It may begin in the substance of the wall of the cervix, near the inner orifice, and also at or near the os externum. It may begin in the cervical glands and in the squamous epithelium of the portio at the same time. This happened in the following case:—

CASE 18.—The patient was thirty-nine years of age; she had had three children, and was admitted into University College Hospital in July, 1885. She said that menstruation had always been regular until July, 1884, when she had a "tremendous hæmorrhage." She had been bleeding for three weeks. She had had no pain until a few months before admission, and then it was only slight, situated in the umbilical region, and of a sharp shooting character, lasting a few seconds. Micturition was normal. She had wasted a little. Menstruation began between the age of fourteen and fifteen; it was regular, lasting two or three days, in large quantity, accompanied by a little backache. Her labours were good; the last was "rather hard." She made good recoveries. The father died of cancer of the stomach; five brothers and sisters died of consumption. The patient was well nourished, fat, but looked very ill, sallow, and anæmic. She was of dark complexion. There was a slight watery discharge from the vagina. There was a growth on the anterior lip of the uterus and inner surface of the canal, extending to the vaginal portion; the mucous membrane over the portio appeared healthy. The posterior lip was healthy. The body of the uterus was somewhat enlarged and freely movable. The cervix was amputated at the inner orifice. She died of septicæmia.

After death no enlarged glands or secondary deposits were discovered. The body of the uterus was healthy. Examination with the microscope showed the squamous epithelium of the vaginal portion to be intact and unchanged up to a point close to the external orifice. Beneath the part of it close to that orifice were many glands, clearly glands of an erosion. Before it terminated at the external orifice it became suddenly much thickened, and beyond this point it was cancerous, and this cancerous part overlapped the glandular cancer which I shall presently describe. This cancerous portion was in part separated from the glandular cancer by glands which were not cancerous. Then we came upon the cancer of the cervix, which appeared to have been developed from the lower cancerous centre. This was developed from the glands in the substance of the cervix, and had not involved the whole of the superficial glands, so that the inner surface of the cervical canal was in the main intact. Higher up towards the inner orifice was the cancer developed from the upper centre near the internal orifice, and this also had grown from the deeper glands, and had left some superficial glands unaffected in the canal. The growth of the cancer from the glands is clearly shown by the transition from columnar epithelium of the glands into cancer. Here we have cancer developing from two points of origin, if not from three—that is, from the glands just below the inner orifice, from glands near the external orifice, and from the squamous surface of the portio vaginalis. It may be asked, What is the relation of the growth of cancer in the squamous epithelium to that growing from the glands? I cannot answer this question. I do not know whether it was an independent growth, or whether it was due to irritation caused by the presence of the glandular cancer in its immediate neighbourhood.

A form of cancer which has not been described before is the squamous epithelioma, which attacks the mucous polypus of the cervix. I have met with only one instance of the kind. It was the following:—

CASE 19.—A patient aged forty-two, was taken into the hospital for a few days to have a small mucous polypus removed. She said that she had been losing a good deal of blood with her periods. The uterus was low down, and a small polypus was found projecting from the os externum. It was seized with forceps and twisted off. The polypus was about three-quarters of an inch in length, and half an inch in diameter at its widest part. Its pedicle was quite thin. A section was made of the growth in its whole length, and this was examined microscopically, and a very curious and not less important state of things was discovered. The lower and larger end of the tumour was capped by a layer of cancerous squamous epithelium, which sent processes into the substance of the growth and into some of the glands. Above the point where the cancer ceased and along the surface of the pedicle many glands opened, and the surface was covered by columnar epithelium. The pedicle

Digitized by Google

was quite healthy. This was a mucous polypus, and evidently had grown from the surface of the cervical canal. The lower portion of it, outside the os externum, appeared to have acquired a squamous epithelial covering, while that covering the base retained its original columnar form. Uterine polypi in advanced age are apt to be malignant, and whenever removed they should be examined by the microscope with a view to ascertain their true character.

The changes in the glands in cancer are various. The glands increase in number, and develop in places where glands are not present in health. They assume forms which are not seen in health, but which are often seen in erosions. The chief and the characteristic changes, however, are those observed in the epithelial lining of the glands. The cells, which are in a single layer in health, become stratified or multiple-layered, and frequently fill the gland, obliterating its lumen. The cells, instead of having a single nucleus, acquire two or more, and they become many-shaped. Not infrequently they form long branching tubes, or strings of cells, and clusters and nests, which sometimes contain horny cells, just like those found in squamous epithelioma; and frequently the true character of the growth can only be made out by tracing it to its origin, or by tracing its mode of growth. The latter method fails, however, in some cases, as in the recurrence in Case 16. Sometimes the cells preserve their original columnar character, but become thinner and larger, and stratified as in Case 17. In other cases the new product consists of small round or oval cells, as in Case 18; and here it would have been impossible to have arrived at certainty with regard to the origin of the growth, but for the discovery of the actual transition of the columnar to the round cells. The cells in the recurrences may maintain the character of those met with in the original growth, retaining more or less their columnar shape, as in Case 15; or they may lose every trace of it, and present characters which are indistinguishable from those of growths from squamous epithelium, as in the recurrence in Case 17.

The starting-point of cancer of the cervix, so far as I have seen, is in the cervical glands. I have seen no case originate in the epithelium of the surface, but it may begin in the glands close to the surface or in the deeper portions of the glands. Of twenty-four cases, the whole cervix was involved in nine when first seen, and it was not possible to discover the starting-point of the growth. It is not impossible, indeed I think it is probable, that in some of these the growth had begun near the inner orifice, and among other reasons for this opinion is the fact that the portio vaginalis was not ulcerated in any one of them, although the whole of the cervix was involved. In eleven the cancer had clearly begun in the lower part of the cervix; in two it began near the inner orifice; in one it appears to have begun in two separate centres, one being near the outer and one near the inner orifice; and in one it had commenced on the surface of a mucous polypus. So that although the upper part of the cervix is by no means uncommon as the starting-point of cancer, yet the lower half appears to be a far more favoured site. Of the eleven in which the disease had begun in the lower part of the cervix, the posterior lip was alone or chiefly affected in six, the anterior in two, and the right commissure and lips in two, leaving the left commissure free. So that cancer appears to show a preference for the posterior rather than the anterior lip of the uterus, the growths retaining more or less the columnar character, as in Case 15, or they may lose all trace of it, and present appearances which are not distinguishable from those of growths from squamous epithelium, as in the recurrence in Case 16.

The forms assumed by cancer of the cervix are various. It may form a polypus hanging from one of the lips; in this case its surface carries for a considerable time a thin layer of normal squamous epithelium, which has nothing to do with the disease. In others it forms a papillary growth on the surface, which penetrates deeply into the wall of the cervix, and then it looks much like the head of a cauliflower; or the growth may begin as a small nodule in the wall of the cervix, as in Cases 14, 15, 16, and others; or, again, it may begin as a nodule close to the inner orifice and gradually extend and involve the whole cervix. I have met with no clear instance in which the disease began on the surface.

The lines of its growth appear simple, and unfortunately they have a direction which is calculated to baffle treatment. If we take first of all the polypoid form, we find here the tendency of the disease is to grow downwards into the vagina and to form a sort of excrescence on the lip. The growth appears to invade the lip for a short distance, apparently for a depth of not more than about three-quarters of an inch; but it involves the whole thickness of it. If we take three or four cases in succession, beginning with Case 14, we shall find the disease commencing as a small nodule near the surface and gradually extending downwards and outwards, and upwards in a less marked degree, invading the wall of the cervix deeper and deeper until it has passed through its whole thickness and has reached the cellular tissue around it, where it luxuriates. At the same time it grows downwards, causing elongation of the lip as well as thickening. In the course of this process of growth the squamous epithelium is retained, but it becomes thinner and thinner, apparently by the tension placed upon it. As the disease progresses, it extends upwards and reaches the internal orifice, and sometimes, but rarely, passes it. This tendency to grow downwards and in a lateral or horizontal direction towards the peri-uterine tissues is very clearly shown by the instances of recurrence which I have related.

Again, when it begins high up, just below the internal orifice, its lines of growth are similar. It has no tendency towards, or preference for, the body. It does not, however, invariably respect the internal orifice, for sometimes it passes beyond it and invades the body. It grows downwards towards the vaginal portion and outwards towards the cellular tissue around, and ultimately involves the whole of the wall in its length and thickness. This was well seen in Case 17 and in another, the only two cases in which this form was observed from an early stage. Thus the lines of growth are mainly outward and downward so as to involve the portio vaginalis and the vesico-vaginal and recto-vaginal septa, but respecting the mucous membrane of the vagina.

Lecture

ON

ACUTE CROUPOUS PNEUMONIA.

Delivered at Mercer's Hospital, Dublin,

BY CHARLES FREDERICK KNIGHT, M.D.;

CONSULTING PHYSICIAN; MASTER IN SURGERY, OBSTETRICS, AND GYNÆCOLOGY; LECTURER ON PRACTICE OF MEDICINE AND PATHOLOGY, LEDWICH SCHOOL; PHESICIAN TO THE HOSPITAL.

GENTLEMEN,—Towards the end of last session you were afforded an opportunity of hearing a paper read on "Certain Peculiarities attending the type of Pneumonia prevalent during the session in Dublin and its immediate neighbourhood," and of subsequently listening to a discussion on the subject, which by special request was chiefly directed to the treatment of the affection. The peculiarities to which attention was directed were complications—viz., pericarditis, pleuritis, peritonitis, congestion of the brain, lungs, and kidneys, and in one case dyspepsia. It was stated that morphia had been administered in some of these cases subcutaneously to allay pain and diminish the number of respirations, also that in one case aconite was administered with benefit, and in another where the right heart was loaded cupping afforded speedy and lasting relief. You heard that some years ago the late Professor Stokes treated cases of this form of pneumonia with large doses of tartarated antimony—six- or eight-grain doses; that some years after this the disease was treated in Edinburgh with diaphoretics, which practice was about the same time followed by Professor Stokes, who stated that the constitutions of the people had changed so much that they were unable to bear the more depressing mode of treatment. Cases were cited where the affection had been preceded by exposure to emanations from sewers, and also cases where it was associated with enteric fever. A close observer of climatic influences on the causation of disease had noticed that the affection was most frequently met with in the months of April, May, and June—that is, during the transition period from wet to dry cold—and suggested that this atmospheric condition may act as an excitant. Opium was advocated to allay pain, and also ergot, though said to be a cardiac sedative, like aconite,

Digitized by Google

still, good effects have been obtained by carefully watching the action of these drugs. Quinine was little noticed except by one speaker, who objected to its administration in the disease because it "dries up the secretions." Large blisters were advocated, but attention was drawn to the fact that they caused localised pleuritis. Lymph had in one case been found on the cerebral arachnoid. Mercury had also been administered with advantage. Attention was directed to a valuable physical sign, obtainable in a large number of cases, which occurred during the session—viz., increased resonance, sometimes amounting to tympany, above the affected portion of lung, *which was not subsequently attacked.*

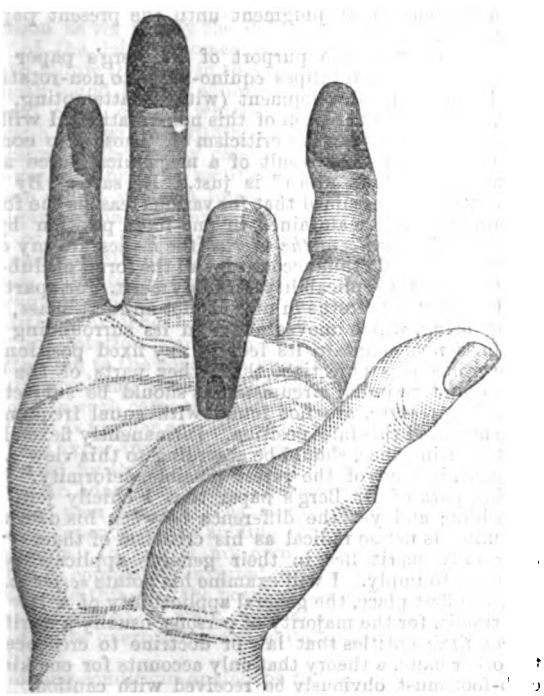
The cases that have come under your notice during the session have not presented any unusual features, and though some might be classed as bad cases, in no instance have we had a fatal termination. You have been taught for years to avoid opium in all forms of pulmonary disease. I admit that in cases of pneumonia where opium or its preparations have been given, the objects aimed at—namely, allaying pain and reducing the frequency of the respiratory acts—have been obtained. But is this advisable? Can we not by other means relieve the pain, and is not the increased frequency of the respiratory acts a conservative process, compensating for the lung tissue, which is inactive? Again, in cases related to me, and also in those recorded, in which opium has been given, complications, especially cerebral, have arisen. Is this due to the cerebral congestion caused by the narcotic? With regard to ergot, does it act as a cardiac sedative in medicinal doses? Doubtless it does so in toxic cases, like digitalis, and in medicinal doses it diminishes the frequency of the cardiac beats; but does it not act primarily by contracting the arterioles, thus raising arterial tension, and causing the heart to contract less frequently, but with more regularity and force? I regard ergot as a most valuable therapeutic agent in this affection, particularly if given in the earlier stages, causing contraction of the vessels, acceleration of the blood current, and limiting the amount of exudation. Quinine is of value as an antipyretic. The term "drying up secretion" is rather indefinite, but if it has the power of limiting the amount of exudation, its administration will be beneficial even in the earlier stages. It is probable that the delirium may in many cases be due to the presence of exudation substance on the arachnoid, and not to the action of narcotics. The hyper-resonance noticeable above the affected portion of lung was, I believe, pointed out by Dr. Hudson, who was of opinion that this preceded extension of the disease to the area which was hyper-resonant; this, however, did not occur in the cases previously referred to, no extension of the disease having taken place. Is not the increased resonance due to distension of the air vesicles which are adjacent to the consolidated portion of lung? The more marked the distension, the greater will be the tenuity of the membrane which forms the walls of the alveoli; consequently there will be stasis of the capillary circulation in that part, thus placing it in a condition most favourable for the manifestation of the disease in question.

It has been remarked—and very properly—that this disease is not suitable for "speculative medicine," and also that drugs have little effect on its progress. Pathologists of the present day nearly unanimously regard acute croupous pneumonia as a specific disease, the exudation substance in the pulmonary alveoli being its local manifestation. The views which I hold are not only in accord with this, but I go further and say that the affection tends to throw out exudation substance on all serous membranes, these being especially "selected" on account of the tenuity of the membranes and transudation from the bloodvessels taking place with facility. The "selective power" of disease is readily seen in many other affections—rheumatism, &c.; and this view with regard to croupous pneumonia explains the phenomena seen in the pericardium, pleuræ, peritoneum, arachnoid, kidneys, &c., and shows us how occasionally these membranes are implicated as well as the pulmonary alveoli. The predilection for the lung tissue appears to me to be due to the fact that its tenuity is greater than other serous membranes; the walls of the vessels are more permeable; the membrane is the most extensive of its class in the body, and its vascularity is far in excess of any other. The exudation in the alveoli obtains its peculiar characters from the presence of so many bloodvessels, and is most likely to become puriform from its constant exposure to the air, whereas the same exudation substance on other membranes does not so frequently undergo the same degenerative changes from the absence of this exciting cause. I would direct attention to the pathological significance of the "raspberry" congestion of the posterior thick margin of the lungs, to the attenuation and fatty condition of the right heart, and finally to the elongated and attenuated condition of the papillary muscles in the right ventricle. At a recent necropsy I found two papillary muscles with a clot projecting into the pulmonary artery, which accounted for the sudden termination of the case.

The following is the treatment which you have seen adopted in the cases occurring in my clinique:—A patient in the first stage is placed on camphor and ergot, with counter-irritation over the affected area by sinapisms or turpentine stupes; if the temperature runs up, quinine is added to the camphor and ergot. Embarrassed respiration from congestion of the right heart is relieved by depletion; but if from extension of the disease, the physical signs point to its advent and call for energetic treatment—viz., larger doses of ergot, using turpentine in the form of inhalation, stupes, and by the mouth. Finally, in the third stage, if the exudation is not being absorbed, stimulants are given, as brandy; if the cardiac action is weak, digitalis is prescribed, carefully watching effects to guard against these drugs embarrassing respiration. In cases associated with "prune juice" expectoration turpentine is especially useful. I regard it as the only remedy on which we may rely with confidence in apparently hopeless cases. It is a stimulant to the pulmonary capillary circulation, stimulating their absorbent functions. It is also a powerful "antiseptic" and hæmostatic, and a therapeutic agent which, I believe, exerts a powerful and beneficial influence on the progress of this affection; and by its free use you have had numerous opportunities of seeing many cases of croupous pneumonia guided to a happy termination in the wards of this hospital.

A CASE OF RAYNAUD'S DISEASE.

BY SEYMOUR TAYLOR, M.D. ABERD., M.R.C.P., &c.,
ASSISTANT PHYSICIAN TO THE WEST LONDON HOSPITAL; DEMONSTRATOR OF ANATOMY, ST. THOMAS'S HOSPITAL.



ON February 8th, 1886, I was called by my friend, Dr. C. F. Wilkinson of Caledonian-road, to see a patient of his. I made the following notes of the case:—

L. D——, aged fifty-six, widow, who keeps a butcher's shop, had been in failing health since her husband died, some years ago. Formerly a very active and energetic woman, she had, during the last four years, been somewhat lethargic; she had increased rapidly in bulk, owing to overfeeding, and, as a consequence, her exercise had been much restricted. She had hitherto enjoyed only tolerably good health, having suffered from occasional bronchitis and rheumatism. She was also subject to quinsy and frequent 'nettle-rash." In addition, she had periodic attacks of "stomach-ache" and looseness of the bowels for many years, the diarrhœa being easily increased by hurry or excitement. Her friends asserted that she was always emotional, being "easily upset," tremulous, and would always cry at the least distressing occurrence; and they constantly noticed her habit of sighing and gaping. The patient herself was always complaining of catching cold, and of always feeling cold except in the middle of summer. There was no history of exposure to malaria.

When I examined the patient—a very large, fat woman—she was complaining of excruciating pain in her hands and fingers and in her toes and feet. The digits in both extremities were affected by the condition known as Raynaud's disease. In the *right* hand the pulp of the index and little fingers was of a dusky, livid, or bluish tint, whilst the whole of the skin, back and front, on the terminal phalanges of the ring and middle fingers was of the same dusky and livid colour, but apparently in a more intense condition. In the *left* hand the same fingers—viz., the index, the middle, and the ring—were affected in a precisely similar way, except that the discolouration was on the skin over the dorsum of the little finger instead of on the pulp. (See engraving.) There were symmetrical black patches about the size of half-crowns on the dorsal metacarpal surfaces of both hands. Over these patches of discolouration the skin was of a dark bluish tint at first, not at all unlike the discolouration resulting from a

Digitized by Google

blow or crush. The cutaneous sensibility was so much increased over the discoloured areæ, that the slightest touch caused exquisite pain; the patient even complained of pain from exposure to the atmosphere. The toes were affected in a similar way; that is to say, in the *right* foot the terminal phalanges of the middle, ring, and little toes were discoloured, tense, and painful, the pulp being the part apparently most involved, although the lividity extended to the dorsal surfaces of the digits. There was, in addition, a patch of discolouration about two inches square on the dorsum of the foot over the bases of the second, third, and fourth metatarsal bones. In the *left* foot the ring and little toes only were seized, but exactly in the same way and degree as in the right foot. There was, however, no patch on the dorsum of the foot. At night there were paroxysms of excruciating pain in the discoloured fingers and toes, causing her, although a woman of some fortitude, to cry out with distress. The pulse was 100, but regular and free from intermission. There were no signs of degeneration in the vessels, nor any obstruction in the main arterial trunks of the limbs, and, in addition, pulsation could be distinctly felt in the digits of both upper and lower extremities. The heart's apex beat was in its normal position; there was no increase of area of cardiac dulness. The only abnormal sign which she had in reference to her heart was a faint systolic murmur over

the aortic valve and in the course of the aorta. The lungs presented a slightly impaired percussion note at both bases, with small crepitation both with inspiration and expiration. Elsewhere there was dry rhonchus, with a slightly prolonged expiratory murmur, which condition, together with great expansion and hyper-resonance of the thorax, is generally held to be characteristic of chronic bronchitis with emphysema. The respirations were 30; temperature 99° F. The hepatic dulness was slightly increased, and there was some slight resistance over the hepatic region, probably showing just such an enlarged liver as one would expect in a patient of her build, occupation, and habits. The urine was of sp. gr. 1025, and contained mucus and an excess of urea, but no albumen or sugar. I could detect no oxalates with the microscope, but amorphous urates were abundant, and there was an occasional crystal of uric acid. There was nothing in the appearance of the urine or in its chemical reaction indicating the presence of blood. The skin over the general surface of the body, but especially on the chest and back, was damp and sodden, and, in addition, was covered with a dense papular exanthem somewhat resembling an irregular initial eruption of small-pox. This condition was perhaps best marked round the loins and abdomen at the line of cincture of her garments. Indeed, beneath the band of an old flannel petticoat which she habitually wore, night and day the skin eruption was so pronounced as to suggest the presence of some local irritant, rather than a constitutional disorder. The eruption was intensely irritating, especially at night, and her skin was in places lacerated by her constant scratching. There was nothing approaching a gangrenous condition in any part of the body except in the hands and feet, as described. The joints of the body appeared quite healthy. Her eyesight was, and always has been, good. I did not, however, examine her optic discs. She had no indications of affections of any of the columns of the cord; the "reflexes," both superficial and deep, were normal. The surface temperature of the trunk and limbs was not, I regret, observed. It may be interesting to note that the weather at the time was very raw, cold, and damp.

The treatment we resolved upon was complete rest in bed; the hands and feet to be thoroughly protected from the atmosphere by being swathed in cotton-wool. Her bedroom, which hitherto had been stuffy, as the windows were always closed to shut out the noise of the street, was thoroughly ventilated. The windows were ordered to be kept open night and day, whilst the temperature of the room was maintained by a brisk fire. We attended to the state of her stomach and digestive organs, and we prescribed mild aperients with a view to ensuring a regular action of the bowels, and thus help to lessen vascular irregularities or disturbance. In addition, we prescribed ether and digitalis, with iodide of potassium. Her diet consisted of milk and broths and other easily digested foods, together with four ounces of brandy daily.

She apparently improved so much under this regimen, that three days afterwards, when I was again asked to see her, the lividity of her toes and fingers had almost disappeared. There was no discolouration on the dorsum of the hands, and, with the exception of some still acute pain in the phalanges of both hands and feet, there was very little trace or appearance of what so recently had seemed such a dangerous malady. But the "local asphyxia" reasserted itself in a few days more, with all the old intolerant pain, which was worse at night, all the symptoms of restlessness, and also of alternate fits of irritability and depression. The skin on the trunk during the remissions was again very active, and the papular eruption, which had somewhat faded during the intervals, became again lit up, and added, by its irritation, to a truly pitiable condition of mental depression and bodily helplessness. The same toes which only a few days since were threatened with death, and which subsequently recovered, were again swollen, with an integument which was tense, shiny, and livid. There was a recurrence of the intolerable pain, and, in addition, the mental agony, as a result of her pain and sleeplessness, was apparent. Such exacerbations, with subsequent remissions, continued, but with decreased length of intervals, for about three or four weeks, till eventually they were replaced by constant pain and discolouration of the toes, and at length death of the parts. This occurred in spite of treatment, which we varied. Gentle shampooing of the limbs above the seat of injury was tried, and this, together with hot anodyne fomentations, appeared to afford more relief than anything. Galvanism was not attempted on account of difficulties in its regular application. Collodion, however, appeared to afford transient reprieve from pain.

On seeing the patient about three months after my first visit, I found that the following destruction had occurred:—

Right hand	Little finger	Slough of pulp.
	Ring ,,	Terminal phalanx exposed.
	Middle ,,	Terminal phalanx had been exposed, and was removed by Dr. Wilkinson.
	Index ,,	Slough of pulp.
Left hand	Little ,,	Slough of pulp.
	Middle ,,	Terminal phalanx exposed.
Right foot	Middle toe	Loss of pulp and nail.
	Little ,,	Do. Do.
Left foot	Ring ,,	Loss of pulp.

Remarks.—There can be no doubt that this case is an example of Raynaud's disease, but with this peculiarity: the patient is not only an adult, but is beyond life's prime. The great majority of cases have occurred, so far as I have been able to gather from the literature on the subject in this country, in children. Dr. Barlow, however, has published a case in an adult, and Dr. Colcott Fox has published two. But my case occurred in a woman who had no obvious sign of heart disease, the only exception being a faint systolic murmur at the aortic orifice. She had no sign of

Digitized by Google

vascular degeneration; there was no history of syphilis. Besides all these, the pulse both at the wrists and on the dorsal surfaces of the feet was good. One could distinctly feel, in addition, pulsation in the digital arteries of both hands and both feet. Another point in the diagnosis is the almost perfect symmetry of the affection, the fingers affected of the left hand being the same as those of the right, although varying in amount. Again, we must note the almost precise parity of conditions in the feet. It is of interest, however, to observe that the toes have been involved to a less extent than the fingers, a condition one would expect to be reversed were Raynaud's disease a true dry gangrene. On the other hand, it cannot fail to be noticed that the pollex and the hallux, both of which are extra well supplied with blood, show no signs of the disease. The darkened condition of the finger ends is not due to ecchymosis. There is no true ecchymosis. The discolouration is transient. It may be present to-day with intolerable pain, but it vanishes perhaps to-morrow, to reappear, it may be, in two or three days.

In criticising the suggestion that the disease is a peripheral neuritis, I must content myself with clinical evidence at present. For until I have had demonstration that such lesion does exist, the clinical aspect of the case must be regarded as against such theory. One of the characteristic features of the disease is its transient nature. To-day the patient is suffering intense agony, and to-morrow, or it may be the next day, there is little or no pain, and perhaps less naked-eye evidence of the disease. This characteristic is, so far as I can understand, opposed to the theory of an inflammatory condition of nerve-endings—a condition which would suggest chronicity in duration, regularity in its painful course, and eventually the production of some atrophic lesion of the part, whether of skin or of joint.

On the other hand, we must recognise the main clinical points which present themselves—viz., that cases of Raynaud's disease occur most frequently in feeble, ill-nourished children, or in adults, in whom, by some cause or other, be it inactive habits, be it defective systolic stroke, or be it some functional disorder of the sympathetic system, the peripheral circulation is diminished. For although the typical lesion occurs in the fingers or toes, patches of "asphyxia" may be occasionally seen in the external ears, the nose, &c.; in other words, those distant parts which are exposed to any disordering influence from without, such as changes of temperature or the like, are the sites in which the disease manifests itself. This looks as though the extremities, or the external ears, or the face, are the seats of local vascular storms—storms which are not of a very wide range, but which are very severe in those localities in which they occur; and that the "chief centres of depression" of such vascular storms occur in the finger or toe ends, or in the tip of an ear or nose, producing, it may be, damage which is easily repaired, or, on the other hand, a destruction which, as in the case above related, amounts to gangrene and the loss of some digits both in the hands and feet.

Tavitton-street, Gordon-square,

ON CLUB-FOOT.

By R. W. PARKER,

SURGEON TO THE EAST LONDON CHILDREN'S HOSPITAL, ETC.

THE interest of the subject, and the diversity of the views held by competent observers as to the mode in which this well-known deformity is brought about, lead me to offer some further observations thereon, and to add some fresh proofs in favour of a mechanical mode of causation. I cannot do better than make the observations a sort of criticism on a paper published two years ago by Dr. H. W. Berg, of the New York Orthopædic Hospital, in Seguin's *Archives of Medicine* (vol. viii., No. 3, pp. 226-48), now defunct, in which this author raises most of the points in dispute.

In the *International Journal of the Medical Sciences* for July, 1886, there is a brief but friendly notice of some views on the pathology and etiology of club-foot, which I recently communicated to the Pathological Society of London conjointly with my friend Mr. Shattock. I cannot sufficiently thank the author of that notice for calling my attention to Dr. Berg's excellent paper, and can only regret that I did not become aware of its publication until the end of last October, the more so as I might then have embodied in the monograph just alluded to, the few criticisms on his paper I now desire to make. As regards the question of priority, delicately hinted at in the above-mentioned journal, I need only say that both Dr. Berg and I have been anticipated, more or less, by so many previous writers that we can both afford to say nothing about priority. Moreover, our interpretation of club-foot rests not so much on individual work, as may be well seen from the rich bibliographical references contained in Dr. Berg's paper, as on the application of that of many workers in the various branches which constitute scientific medicine. I must thank Dr. Berg, however, for his mention of my first paper, which appeared some two years before his own, and again express my regret that I could not (for the reason given) reciprocate this kind attention by a reference to his views in my later, more detailed, and illustrated monograph. As regards one other remark in the *International Journal*, "that the American contributor has carried his observations a step in advance of the authors', and followed them to their legitimate logical conclusions, which for some reason Messrs. Parker and Shattock have avoided," I will only ask for a suspension of judgment until the present paper is concluded.

Premising that the purport of Dr. Berg's paper is to attribute congenital talipes equino-varus to non-rotation of the limb during development (without attempting, however, to explain the reason of this non-rotation), I will pass on to discuss how far his criticism of "those who consider the deformity as the result of a mechanical force acting upon the fœtus in utero" is just. He says: "By these authorities it is assumed that for various reasons the foot, in certain cases, is maintained in one fixed position by the *pressure of the walls of the uterus* [the italics are my own]. This theory would thus account for all the forms of club-foot, and this general applicability is its only merit. For, apart from the fact that the fœtus in utero is not an inert mass, but a living being, which moves about in its surrounding fluid and does not maintain its feet in any fixed position, the theory has this objection, that other parts of the body, which under similar circumstances should be subjected to a similar pressure, are not found with equal frequency to have acquired this false position. Permanently flexed knee-joints, for instance, should be according to this view a very frequent, instead of the rarest possible, deformity." It is on this part of Dr. Berg's paper that I chiefly join issue with him; and yet the difference between his own views and mine is not so radical as his criticism of them—"that their only merit lies in their general applicability"—is intended to imply. I will examine his points *seriatim*.

In the first place, the general applicability of a law or a doctrine is, for the majority of persons, usually a merit, and *primâ facie* entitles that law or doctrine to credence; on the other hand, a theory that only accounts for one kind of club-foot must obviously be received with caution. Now, although Dr. Berg applies his views to congenital equino-varus only, and not to calcaneus, these two—the common—forms of congenital club-foot are so clearly due to some common mode of causation that, *mutatis mutandis*, only such mode of causation can be acceptable as will apply to each. Non-rotation of the limb, however, will not explain calcaneus, and for this reason, therefore, I regard Dr. Berg's explanation not as wrong, but rather as insufficient, due to the fact that Dr. Berg has not followed his observations to their legitimate logical conclusion.

In the next place I must object to the idea that when the foot is "maintained in one fixed position" this is always due to "pressure of the walls of the uterus." This latter is only one of several mechanical forces acting on the fœtal foot. Direct pressure of the uterine wall undoubtedly occurs in certain cases, but I doubt very much whether it comes into play in any large proportion of the cases of club-foot which come under the surgeon's observation. A more frequent force, only to mention one of several, is interlocking of parts of the fœtus, one in another. This condition, described by various authors, leads to deformity without the direct action of the uterine walls, and cases have been figured which undoubtedly originate in this manner. According to Dr. Berg, the "mechanical theory" has also this objection: the fœtus in utero not being an inert mass, but a living being moving about in its surround-

Digitized by Google

ing fluid, and not maintaining its feet in any fixed position, other parts of the body ought to show signs of similar pressure *with equal frequency* [the italics are my own]. Here again I find myself at variance with Dr. Berg. It seems to me that a very sufficient reason why other parts suffer less frequently than the feet may be found in their being less anatomically disposed to a deformity so consistent with healthy development elsewhere. Is it not highly probable that when direct pressure affects the head or the abdomen, the life of the fœtus is endangered and that abortion takes place? But that both hip- and knee-joints do frequently suffer analogous deformity is known to every orthopædic surgeon, certainly to every surgeon who sees much of children's diseases. In the severer forms only are these deformities rare; in their lesser degrees they are matters of every-day experience. But the surgeon must look for them not among his orthopædic cases, but among new-born infants; there he will find that probably not less than 30 per cent. are quite unable to fully extend the thigh or the leg for a variable number of days or weeks after birth. As regards the hands, it will be remembered that Cruveilhier explained their comparative exemption by the protected position they occupy during fœtal life.

Dr. Berg further says (*op. cit.*, p. 228):—"There are no adhesions to overcome. On the contrary, motion, as far as is possible in the deformed position of the joint, is good; and as soon as we rectify the deformity by tenotomy, the motion of the joint becomes unrestricted." I am quite unable to follow Dr. Berg in this opinion also. Mr. Shattock and I both found fibrous adhesions within the ankle-joint in several cases, one of which (Case 6) is figured in our monograph. It will be within the knowledge of all orthopædic surgeons that many cases of club-foot, especially of equino-varus, cannot be rectified after tenotomy. I have elsewhere shown what an important part is played by the tarsal ligaments in maintaining the deformity. Even after section of both ligaments and tendons there are cases which resist rectification. It is quite probable that this resistance is due to the presence of such adhesions between the astragalus and the tibio-fibular articular surfaces.

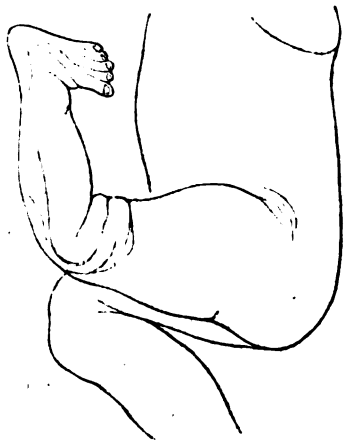
If additional evidence be required to show the insufficiency of the "non-rotation" causation of congenital varus, I will draw attention to the condition known as "crus varum"—a deformity involving the foot and the whole limb up to the hip-joint. In such cases the talipes proper is generally very marked, but is further aggravated by the inward rotation—I would say hyper-inverted position—of the limb. Such cases are described by Dr. Berg's distinguished countryman, Prof. Sayre, by Mr. Adams, and some other authorities, and I have myself also seen several. The chief difficulty in treating these cases depends on the abiding tendency of the limb to turn inwards. In one of my own cases, a little girl, the feet could be completely inverted, so that the heels looked forwards; and this was the position the feet assumed when she first attempted to walk, even after the talipes proper had been quite overcome, until suitable instruments were applied.

As showing conditions analogous to club-foot, I may cite the following cases from my own practice, and while admitting that they are rare, I would carefully point out that their rarity depends on the *degree* rather than on the *nature* of the deformity. As I have already said, the hip- and knee-joints do not lend themselves, anatomically, to severe deformity; nor does the ankle-joint, and it is for this reason a talipes calcaneus is far less severe as a deformity than equino-varus. The former concerns a hinge-joint, and involves movements of flexion and extension only; the latter, besides these movements, involves others (chiefly of rotation) between the calcaneum and astragalus, and between these bones and the fore part of the foot, at the transverse joint. It is this multiplicity of joints and of possible movements which renders the foot so much more liable than the hip or knee to be influenced by slight causes, while the complicated nature of the deformity ensures its coming under the care of a surgeon, and of being reported.

Fig. 1 represents a child with genu recurvatum—a condition of the knee-joint in every way analogous to talipes; owing to malposition in utero, the limb has not been able to pass through that series of positions which is necessary to the development of muscles and ligaments (chiefly) of sufficient length to ensure healthy movements in independent life, and thus certain movements of the knee- and hip-joints were faulty. The deformity, like talipes, yields to suitable manipulations. This infant was only seventeen hours old when first seen. There had been a normal presentation, and labour was quickly accomplished. The deformity affected the left side only.

Fig. 2 represents a still severer form of the same deformity, associated with talipes calcaneo-valgus. The infant was fourteen days old when first seen. The right limb was more affected than the left. The right knee could not be flexed at all; it appeared quite fixed, and resisted all attempts at flexion. The thigh could be extended a few degrees only. The left limb differed in having a few additional degrees of movement. The child was born in, and when naked and left to itself it for some weeks resumed, the position indicated in the drawing. During intra-uterine life the limbs had remained extended on the trunk, with the feet pressed against the chest. In this case there can be no doubt that talipes was caused by uterine environment; the muscles and ligaments were, as a consequence, so short that the joints

FIG. 1.



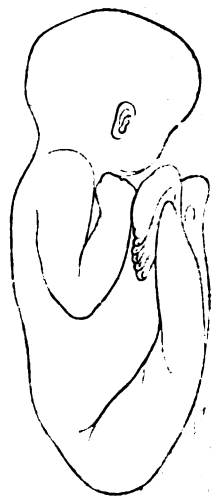


FIG. 2.

could not be extended until the shortened structures had been stretched.

These cases and the whole subject of talipes will be dealt with more fully in a work I have nearly completed, and am about to send to press. More especially I hope to point out the part played by certain of the tarsal ligaments in maintaining the deformity of club-foot, and the importance of dividing them in view of a speedy and radical cure of the deformity.

These observations dispose, I think, of the chief objections urged by Dr. Berg against the "mechanical theory." After discussing other alleged causes and demonstrating their insufficiency, he proceeds to enunciate his own views. He says:—"I shall endeavour to present in a new light a view which, although feebly advanced by some authorities from time to time, has never been supported by well-observed facts, and has therefore gained no adherents. This theory supposes that the deformity of pes equino-varus is due to an *obstruction in the normal development of the feet during some period of intra-uterine life.*" I am quite prepared to endorse this italicised sentence, and am quite sure Mr. Shattock would do the same. For reasons to be presently given, I cannot endorse the earlier part of the above quotation from Dr. Berg's paper. He next proceeds to epitomise the development of the lower limbs, more especially as to the rotation they undergo during the earlier weeks of intra-uterine life. He then says that the deformity "is not due to pressure," but to "non-rotation inwards, or a retarded rotation inwards of the lower extremities." He thus very materially limits the method of causation, and rather goes back on himself and his opinion previously expressed in the italicised sentence just quoted above. In this I think he is wrong, and that Mr. Shattock and I have the advantage over him, since we point out the direct mechanical agencies, which are the *active causes*; it being hardly possible to conceive non-rotation or retarded rotation of the limbs as *spontaneous*; this non-rotation itself must have some active cause. It would seem not improbable that the vitality of a fœtus may be low and insufficient to carry through those developmental processes on which the

Digitized by Google

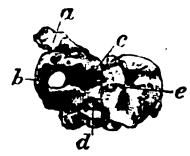
integrity of the limbs and other organs depend. Should this be very marked, death of the fœtus and abortion take place. When the want of vitality is more localised, perhaps it results in deformity or deficiency in the organ chiefly affected; but these are mere speculations, difficult to test, and obviously inapplicable to the majority of cases of congenital club-foot, since, as Dr. Berg himself admits, the limbs are fat and well-nourished, of normal surface temperature, showing no signs of the atrophy which would follow on deficiency of vital power. What, then, are these active causes? Without pretending to have explained all the methods in which a *mechanical force* may act, I think good evidence may be found in our monograph in favour of the mechanical mode of causation as the most reliable and most satisfactory for the majority of cases met with in practice.

If Dr. Berg still entertains the view that the developmental processes to which he alludes in his paper have not been sufficiently taken into consideration when attempting to explain the production of club-foot, and have found no adherents, I would refer him to an admirable exposition of the whole subject entitled, "Ueber die Fötalkrümmungen, namentlich in Bezug auf die Bedeutung der angeborenen Verdrehungen der Bauchglieder," by the late Professor Eschricht of Copenhagen, and to other writings by this distinguished physiologist. I think he will find that Professor Eschricht has anticipated him in most of his conclusions. By consulting the literature of club-foot Dr. Berg will also find that Eschricht's doctrine has many adherents; it has been fully appreciated by writers of eminence, such as Billroth, Volkmann, Lücke, and many others of lesser note, including myself. The great merit of Eschricht is that he was *original* in his enunciation of this doctrine and far ahead of his compeers. He founded it on researches, both human and comparative, carefully and laboriously carried on for years. Among other interesting points he showed that one particular form of monstrosity—the siren—depends on a total absence of this rotation of the limbs, and he thus explained how it was, in such cases, that fusion takes place along the outer border of the limbs, and not along the inner border, as many have erroneously supposed. If Eschricht's views appear to be neglected, it is due to the fact that they are unconsciously included in the larger "mechanical theory" which is at last gaining ground, and to one probable factor in which Dr. Berg has contributed the weight of his authority.

In conclusion, I hope that Dr. Berg, as well as the writer in the *International Journal of the Medical Sciences*, will accept the assurance of my regret that I did not sooner meet with Dr. Berg's paper, and that they will bestow careful consideration on the points on which they and I seem to differ.

Old Cavendish-street, W.

CASE OF



SEPARATION BY NECROSIS OF THE OSSEOUS LABYRINTH OF THE RIGHT EAR, AND ITS REMOVAL AS A SEQUESTRUM FROM THE EXTERNAL AUDITORY CANAL.[1]

BY THOMAS BARR, M.D.,

SURGEON TO THE GLASGOW EAR HOSPITAL; LECTURER ON AURAL SURGERY, ANDERSON'S COLLEGE.

THE specimen shown in the accompanying figures was removed on June 1st from the right ear of a boy aged eleven years. It consists of an osseous labyrinth with its three divisions—the vestibule, semicircular canals, and cochlea—clearly marked. In examining the specimen from the outer aspect (Fig. 1)—that is, from the direction of the cavity of the tympanum—we see the opening of the fenestra ovalis (Fig. 1, *e*) leading into the vestibule considerably enlarged by carious erosion; below this, and separated from it by a part of the outer wall of the first turn of the cochlea, there is the fenestra rotunda (Fig. 1, *d*) leading into the scala tympani of the cochlea. Behind and above the fenestra ovalis the external or horizontal semicircular canal (Fig. 1, *b*), with its ampullary enlargement, is seen in its whole extent. Springing from the upper part of the vestibule, the superior semicircular canal (Fig. 1, *a*) is seen to about half of its extent. The Fallopian canal, with its contained facial nerve, is absent at that part of its course where it lies above and behind the fenestra ovalis. The outer wall of the cochlea, considerably thickened, is seen in front (Fig. 1, *c*). On the inner aspect of the specimen (Fig. 2), or that corresponding with the interior of the cranium, there is a cavity of considerable size (Fig. 2, *c*) leading into the vestibule and the scala vestibuli of the cochlea; this

FIG. 1.

Outer aspect of sequestrum.

FIG. 2.

Inner aspect of sequestrum.

opening is evidently a carious extension of the apertures of the lamina cribrosa. In its interior can be traced part of the osseous spiral lamina of the cochlea. On this side of the specimen are two other smaller apertures in the vestibule; one is that common to the two united extremities of the superior and posterior semicircular canals (Fig. 2, *d*), and the other is the ampullary end of the posterior semicircular canal—the only part of this canal represented in the specimen. The superior semicircular canal (*a*) and the horizontal canal (*b*) are also seen on this side of the specimen.

The boy from whom this sequestrum was removed had been affected for ten years with profuse purulent discharge from his right ear, which had originated in an attack of scarlet fever when a year old. Facial paralysis of the corresponding side appeared shortly after the commencement of the discharge, and has continued ever since. He was brought to the Glasgow Ear Hospital on June 1st, mainly in consequence of severe pain in the affected ear. A polypoid growth was seen to occupy the orifice of the ear, and on examining with a probe a large loose sequestrum was felt in the external auditory canal. After the polypus was removed by means of a snare the sequestrum was with some difficulty extracted with a pair of forceps. The external auditory canal was considerably dilated and its lining much excoriated, but after the removal of the necrosed bone the discharge quickly subsided, and within two weeks it had completely ceased, while the interior of the ear had become healed. There was apparently at no time any mastoid complication. It has also to be mentioned that the boy suffered a few years ago from hip-joint disease, which went on to suppuration, and has left behind considerable shortening of the left leg. There is, as might be expected, total loss of the hearing power in the right ear, as tested both by air conduction and by bone conduction. A vibrating tuning-fork or a loudly ticking watch, applied to any part of the head, is heard only in the left ear, while neither a watch, tuning-fork, nor Politzer's Hörmesser is perceived by air-conduction, if the opposite external auditory canal is efficiently closed. The voice spoken into a hearing tube inserted into the ear is heard—evidently, however, by the other ear through osseous conduction. In view of the loss of the semicircular canals on one side, it is interesting to note that this boy has at no time suffered from giddiness or staggering. This seems to support the theory that disturbance of the equilibrium, which has its origin in the semicircular canals, is due to irritation from disease or injury of these canals, while, on the other hand, absence or destruction of the semicircular canals has no effect upon the equilibrium. The facial paralysis is almost complete. As the trunk of the facial nerve was without doubt destroyed at that part of its course where it ordinarily lies on the inner wall of the tympanum, it was important to determine accurately the condition of the muscles supplied by that nerve; and in order to insure this accuracy I asked the President of the Glasgow Pathological and Clinical Society to examine the area of supply, both electrically and otherwise. The following is his report of the condition as tested on the 5th and 7th of June:—

"There is almost complete paralysis of all the muscles of expression on the right side, and the face is drawn to the left; the right eye seems lower than the other, probably from the relaxed state of the occipito-frontalis. The right eye can be closed to a much more considerable extent than is usual in bad facial paralysis, but the part of the sclerotic below the cornea can be seen. He can close both eyes simul-

[1] This specimen was shown to the Glasgow Pathological and Clinical Society on Nov. 8th, 1886.

Digitized by Google

taneously pretty well, but he cannot wink with the right alone. The right side of the lips has also some slight power of movement, and the right buccinator contracts feebly on the finger introduced between it and the gums. There is also some movement of the ala nasi on the right in sniffing; otherwise the whole right side of the face seems flabby and expressionless. The cornea is clear; the eye waters only slightly on exposure on a cold day; the movements of the eyeball are good, and the sensation of the paralysed side of the face is perfect. There is a pretty distinct deviation of the uvula to the left; no deviation of the tongue. On testing with the faradaic battery no response could be obtained in the paralysed muscles, even when using strong currents. Ordinary strengths of the galvanic battery likewise failed to secure contractions. On getting up to twenty-seven or thirty elements, and using an interrupting handle well soaked in salt water, the slightest recognisable quivering was produced in some fibres of the orbicularis in the lower lid, and in the orbicularis at the angle of the mouth. During this testing marked contractions of the muscles of mastication sometimes occurred." Dr. Finlayson again reports on November 8th: "No distinct change since above note. The sense of taste was not tried last time, and the boy does not seem very ready to give assistance in this testing."

It is somewhat surprising that in such a case as this there was not extension of the disease to the brain or its membranes. In cases where sequestra have been found after death in the inner wall of the mastoid process, in contact with the dura mater, but without injuring the intracranial contents, there has usually been found localised thickening of the dura mater. Probably thickening of the dura mater also exists in this boy in the region of the posterior surface of the petrous bone—a conservative process of nature, by which a barrier is erected against the propagation inwards of the purulent disease. It is very curious to see how the inflammatory process has caused death and separation of only the hard ivory-like osseous tissue which forms the encapsuling walls of the labyrinthine cavities, as if these walls were separate and distinct, which they are not, from the adjoining more cancellated bone. The disease has really provided us with a preparation which the anatomist finds it difficult and tedious to prepare by dissection.

It only remains for me to say that while a number of cases are on record of individual sections of the osseous labyrinth, especially the cochlea, being exfoliated, there are comparatively few cases recorded of an exfoliated labyrinth having its various parts so well represented as in this specimen. A pretty complete specimen which was placed in the museum of the London College of Surgeons, but has since disappeared, is mentioned in Toynbee's book, and is fully described in the eighth volume of the Pathological Society's Transactions. Wilde also describes one in his "Aural Surgery" (p. 377), and refers to it as "one of the most extraordinary pathological specimens of diseased bone perhaps in existence." In the *British Medical Journal* of June 13th, 1885, Dr. Pye of London describes a specimen removed from the mastoid process somewhat similar to the one I have described. Another case is related in the same journal by Dr. Phillips of Bolton on July 4th, 1885. In his paper Dr. Pye gives an interesting account of the more important recorded cases of necrosis of the labyrinth, both partial and complete.

ON THE OCCURRENCE OF A POISONOUS PTOMAINE IN MILK.

BY R. H. FIRTH, F.R.C.S. ENG.,
SURGEON, ARMY MEDICAL STAFF.

FROM time to time one reads or hears of people who having partaken of certain milks or ices, and even cheeses, are afterwards the subjects of symptoms indicative of an irritant poison. I am at the time of writing unable to quote instances of such with any accuracy, but readers of THE LANCET will doubtless be able to recall several such cases. During the past few months my attention has been devoted to an inquiry into the circumstances of a case of the kind.

On August 3rd, 1886, certain men in the British Infantry section of the Station Hospital, Meean Meer, were seized with nausea, vomiting, dryness of the fauces, with a sense of constriction, colic, purging, and in some few a tendency to collapse, while in others there was a disposition towards stupor. On the same day nine out of ten men in the military prison were affected with similar symptoms in greater or less severity. Under simple treatment all the cases recovered. The circumstance naturally attracted the attention of the medical officers, and on inquiry it was found that the only men affected in hospital were those upon "milk" or "low milk" diets. Also it was noted that the one prisoner who had been free of the symptoms was a man who, not liking the taste of his milk at breakfast, had refused to drink it. Curiously enough, the others remarked nothing to be wrong with the taste or smell. This common factor in the dieting of the two groups of men directed suspicion towards the milk supplied. Further, it was noticed that the milk supplied to the British Infantry section of the hospital and to the military prison were from one and the same contractor, while the milk sent to the Artillery section of the hospital came from another contractor, and amongst the Artillery sick no similar symptoms had followed the drinking of the milk. Unfortunately, none of the suspected milk remained from the hospital, but the unconsumed pint remained at the prison. As officiating staff surgeon at the time, I inquired into the matter, and secured the residue of the milk. The contractor was reported to the commissariat officer, and fined on the strength of the circumstantial evidence. Analysis of the sample of milk left gave the following result: Sp. gr. 1025; solids not fat, 9·6; caseine, 4·1; fat, 3·0; milk sugar, 5·04. It was pronounced therefore to be a fairly good milk. I inspected the premises of the contractor (a native), and examined all his utensils and his cows. His premises, while not being all one could wish, were yet good for a native of his class. However, I unhesitatingly condemned the condition of two of his pans, which were markedly unclean, emitting a repulsive odour, and evidently had been unwashed for some days. Though unable to extract in so many words the fact that these vessels had been used to store the milk in on the morning in question, the presumption was that they had been. The weather at the time was very hot, and specially favourable to organic decomposition, fermentative or otherwise. The cows appeared healthy, well nourished, and the udders quite free from fissures, sores, &c. Reflection on this case led me to try to isolate, if possible, and if such existed, any organic poisonous product from the milk under suspicion. Further consideration favoured the belief that any such product must be a ptomaine.

As the quantity of milk for disposal was small after the ordinary analysis had been finished, I adopted the following method. The milk, being coagulated, was filtered. The filtrate was nearly colourless and acid. This was neutralised and made feebly alkaline by potassium hydrate, and afterwards well shaken up with ether. This was now allowed to stand for awhile, and the ethereal stratum removed by a pipette, and then allowed to evaporate spontaneously. After the completion of this process a moist semi-crystallised residue was left. This appeared to be aqueous, probably the result of a certain amount of water which the ether had taken up. This concentrated residue had a mawkish sickly odour, and a strongly pungent taste when put on the tongue. Trying some carefully myself, I was soon after conscious of marked nausea and dryness of the fauces, followed by headache. Though without the prominent symptoms obtained from the original milk, I suspected I had more or less reached the *fons et origo mali*. Following the idea up, I gave all the remaining residue after evaporation to a small pariah dog belonging to one of my servants. The effects were pronounced: the dog was within fifteen minutes purged, vomiting, and obviously ill. He gradually recovered, and six hours later I had him killed. The stomach and intestines, though containing a serous and frothy fluid, were quite free of congestion or inflammatory action.

Deeming this result so satisfactory, I decided to follow up the inquiry and see whether this product was always present in milk, and, if so, under what circumstances. Taking six samples of fresh milk, I tested them all in the above manner, and in each case failed to procure any toxic residue. To see whether time or degeneration of its constituents was the essential factor for its formation from milk, I obtained a gallon of fresh milk, and by analysis assured myself of its goodness. This I placed in eight clean glass stoppered bottles, and put the same in a room having a mean tem-

Digitized by Google

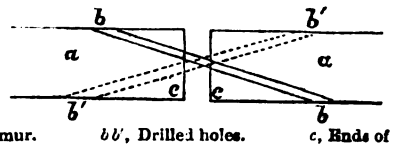
perature of 80° F. From time to time, usually every twenty days, a bottle was opened and the milk examined for the ptomaine, as before explained. Negative results were always obtained until Oct. 19th, when bottle No. 6 was examined and yielded a white acicular crystalline substance having the same odour and taste as that found in the originally suspected milk. Its action on myself and on four dogs and a cat was identical—namely, nausea, vomiting, purging, thirst, frontal headache, and collapse. Bottles 7 and 8 yielded the same product. My means at command are too imperfect to enter into any precise analysis as to the exact nature of this product. I believe it to be a ptomaine, and to which I offer the name "lactotoxine." How and why it is formed seem obscure. It is evidently an effect of decomposition. Microscopical examination of the milk showed no specific organisms on which to father it beyond some common forms of oidium and penicillium. The milk was not unpleasant to taste or smell.

The literature on this topic at my command is so limited that I am unable to refer to the writings of others; but that ptomaines, or similar bodies, do exist in organic fluids under certain circumstances is probable, and it is only by patient and careful investigation as to their causation and composition that we may hope to unravel some frequent but obscure forms of dietetic poisoning. As but an indifferent contribution to this subject, and with a keen sense of its imperfections, I somewhat hesitatingly furnish this paper; but, in conclusion, would remark how well this case illustrates one of the many difficulties we in India have in guarding the soldier from the dirty habits and carelessness of the native food contractors. Notwithstanding the care taken in hospitals to see the milk drawn from the cows on the premises, and under supervision, yet on this occasion some evasion of the precautions must have occurred either by mixture of stale milk with fresh, or by employment of unclean vessels. That the cows themselves were not to blame is supported by the fact that on the next day the very same animals gave milk unproductive of toxic effects.

Meean Meer, Punjab.

NOTES ON A CASE OF UNUNITED FRACTURE OF THE FEMUR.

BY ROBT. W. LEEMING, B.A., M.B. CANTAB., M.R.C.S.



THE following notes may prove of interest as showing the success attending the use of ivory pegs in ununited fracture of a large bone like the femur, and the power of recovery in youth after severe injury.

On Sept. 27th, 1884, J. B——, aged twelve years, an errand boy, was admitted into the Kendal Hospital suffering from injuries received on the railway. From a subsequent account by himself, he was standing on the metals, when a waggon coming up behind him knocked him down, and "he thinks ran over him."

On admission, there was a large open wound over the lumbo-sacral region, about four inches and a half in diameter; just below the left trochanter was a second wound, two inches and a half in diameter, showing the tendons &c. perfect and uninjured, and having a long subcutaneous connexion with a similar opening on the outer side of the thigh a short distance above the knee. The right thigh had sustained a compound comminuted fracture at the junction of the upper and middle thirds of the femur. All the wounds, especially that at the seat of fracture, were thoroughly washed out with carbolic acid (1 in 40) and dressed with iodoform wool. The fractured limb was extended to its original length, and placed on a bracketed Liston's splint. The temperature was 96·6°; the pulse 136, small and feeble. The patient was ordered brandy, and a mixture containing carbonate of ammonia and digitalis every two hours.

The temperature gradually rose to 104° on Oct. 1st, after which date both that and the rapidity of the pulse subsided, till on the 10th both became normal, and remained so. On the third day a gangrenous slough had formed over the seat of fracture, and the veins showed great congestion around. Hot fomentations were applied, and the slough separated on Oct. 3rd, when all the wounds assumed a healthy appearance. Owing to the frequent dressings required by the wound on the back it was quite impossible to keep the limb in perfect position, more especially as there was a fragment over an inch in length lying between the ends of the broken bone. It was therefore decided to keep the parts in as good position as possible until the wound on the back was healed. This proved a very tedious process, and was not completed till the beginning of March, and then only by the aid of skin-grafting.

At 12 noon on March 10th the patient was placed under chloroform, when examination showed the end of the lower fragment to be drawn backwards and upwards towards the ischial tuberosity, and firmly fixed in that position, while the upper fragment was tilted forwards. An incision was made the full length of the cicatrix, and a second one at right angles to the first meeting it in the middle, when a fragment of dead bone an inch and a half in length was removed. The upper end of the lower fragment was so firmly embedded in connective tissue that the greatest difficulty was experienced in reaching it. This was done by means of the finger-nail and a blunt-pointed instrument to avoid risk of hæmorrhage, the whole circumference of the bone from the wound upwards having to be stripped before any reduction could be effected. When this was done the end was sawn off, and the upper fragment was treated in the same manner, its end also having to be stripped for some considerable length before it could be brought into apposition. Having been under chloroform for more than an hour, it was found necessary to proceed no further for the present; the limb was therefore placed on a back splint and firmly bandaged, with the ends of the bone in contact. The lad stood the operation remarkably well, the temperature being highest (100·4°) on the 13th and 14th; but as the position was not maintained, it was determined to try ivory pegs as a *dernier ressort* before amputation. On the morning of the 16th the boy was placed on a fracture board and encased in plaster-of-Paris, strengthened with bell wire, from the shoulders downwards, with the exception of the anterior parts of the chest and abdomen, the second limb, and an opening eight by six inches in extent over the wound. By these means the body and limb were completely

a, Femur. *b b'*, Drilled holes. *c*, Ends of bone.

fixed, and he could be moved when required without injury. In the afternoon of the same day, under chloroform, several strands of strong silk were passed beneath the lower fragment, which was then drawn forwards and held in position by an assistant, while the upper fragment was depressed till accurate contact was secured. Holes were then drilled through both ends of the bone in opposite directions, as is shown in the above diagram. Into these holes two ivory pegs, each two inches in length, were driven, their crossed direction preventing any displacement; the wound was then closed and dressed with iodoform wool as before. On the 26th the temperature rose for the first time to 102·6°, and as it remained high a large portion of the plaster in the neighbourhood of the wound was removed, as it had become saturated with discharge, and a fall of temperature followed; this was on April 2nd. A large amount of callus had by this time been formed, the diameter of the bone at this part being nearly four inches; and a few days later all the plaster was removed and the bracketed splint again brought into use. On May 9th the temperature suddenly rose to 104·4° without any apparent cause; the exhibition of quinine caused a fall, which was again followed by a rise on successive days. On the 16th a small red swelling, not unlike a boil, was observed near the cicatrix; while examining this, half of one of the ivory pegs was expelled spontaneously, falling some distance from the limb. After this the temperature remained normal, and in about a fortnight the second half of the peg came away through the same opening. The ivory shows deep marks of absorption over the whole surface, and as more than twelve months have now elapsed since the operation, it seems very probable that the other peg has by this time been absorbed. On July 16th he was discharged cured, being able to walk easily with a thick sole to his boot, and even to ride on horseback.

The two points which seem of most importance in this case are the difficulty in keeping the broken limb in position and the absorption of the pegs. From experience the splint

Digitized by Google

was evidently powerless to keep the limb so firmly in position as to prevent the two thin pieces of ivory from being broken, but by encasing the body and limb in plaster almost complete immobility was maintained. With regard to the second point, the marked absorption of the material used, as shown by the appearance of the portions which came away, affords an argument in favour of using ivory where possible instead of wire, presenting as it does the chance of a wound healing by first intention, and no further operation being required. Of course this plan could not be adopted in the case of a slender bone, since the drilling of so many holes would render the ends too weak to bear any strain.

Kendal.

OVARIOTOMY FOR THE REMOVAL OF A DERMOID CYST.

By E. SINCLAIR STEVENSON, M.R.C.S., L.R.C.P. Ed.

THE following case illustrates the rapid growth of dermoid cysts.

Mrs. B ——, aged thirty (second pregnancy, last eighteen months ago), a spare and healthy person, sent for me in September, 1885, suffering from symptoms suggestive of pelvic hæmorrhage occurring during menstruation. The locality of the effusion could be easily felt anteriorly in the left inguinal, and per vaginam filling the posterior cul-de-sac and left fornix. The patient being thin, a thorough examination of the pelvic cavity could be made. The right side was free from any suspicious enlargement. The pelvic hæmatocele gradually disappeared under careful treatment. On Nov. 26th of the same year I saw her again, and found a lump the size of a turkey's egg projecting in the hypogastrium, inclining to the right, freely movable, hard, not fluctuating, with little pain and no inconvenience. She had menstruated since I had last seen her, and there had been no increase in the flow. The case was carefully watched at frequent intervals. At the end of three months, during which she had menstruated regularly, the growth had reached a level two inches above the umbilicus, filling the abdomen anteriorly, leaving the flanks clear. Fluctuation was now distinct, percussion at any point of the circumference producing an equal wave in all directions, pointing to the existence of a large unilocular cyst. The patient felt very little pain or inconvenience besides that of weight; but a few days before she had been seized with a sharp pain in the right side, suggestive of a twist in the pedicle. For this and other reasons, especially that of the rapidity of the growth, it was decided to interfere.

The operation on Feb. 21st, 1886, was done with strict antiseptic precautions. The room was carbolised with spray for half an hour previously to the operation, other details being strictly carried out on Listerian principles. There were no adhesions, and no hæmorrhage whatever. The cyst contained about two pints of sero-albumen, with lymph flakes and oil and fat floating in it. While tying the pedicle a small secondary cyst burst and discharged its sebaceous contents into the peritoneal cavity, necessitating a careful toilet. The growth was a cyst of the right ovary, containing bunches of long hair in the cavity, short hair growing on the lining membrane, and between the walls anteriorly a flat bone half an inch long with two teeth. Besides which there were five smaller cysts, containing sebaceous matter and hair. Carbolised silk was used for tying the pedicle and for the sutures, and a dressing of salicylated cotton wadding externally. The temperature immediately after the operation was 99°. She was kept on ice for two days, with the addition of injections of peptonised beef-tea. On the third day she had milk added to her diet. Menstruation occurred on the second day after the operation, and lasted four days. On the twelfth day the wound was healed, and on the twenty-first day she got up.

Remarks.—The interest of this case lies in the clear data which I had, enabling me to calculate almost to a certainty the duration of the growth. Thus in three months the cyst grew to the size of an adult's head. The success of the operation I attribute to its having been done early, and to the skilful assistance rendered me by my friends and colleagues, Drs. Murray, Parson, and Evans.

LONDON HOSPITAL.

HEPATIC ABSCESS.

(Under the care of Dr. RALFE.)

THE surgical treatment of tropical abscess of the liver has excited considerable discussion in the past, and it was at one time advised that such abscesses should be left to break spontaneously. Since the introduction of improved methods of drainage and the employment of antiseptics, of which the following case is an example, the opinion of the majority will be found to coincide with that expressed by Dr. Ralfe in his remarks. This mode of treatment, however, cannot in all cases supersede the use of the aspirator or trocar, the employment of which is still required where the diagnosis is obscure, or the abscess deeply seated and possibly of small size. That the use of the aspirator may be beneficial where no abscess exists is proved by a case published by Dr. Ralfe in THE LANCET of 1876. For the notes of the case we are indebted to Mr. J. F. Johns.

John A——, a sailor, unmarried, a strong, muscular man, came to the hospital on Nov. 15th last, complaining of a feeling of uneasiness in his abdomen, and of "a lump there." The patient was pale and tremulous, and looked exceedingly unwell. On examination a fluctuating tumour was felt about an inch and a half below and a little to the right of the xiphoid cartilage. The tumour was very soft, and the fluctuation well marked. No pain was experienced by the patient in the region either on palpation or percussion, nor indeed had he ever noticed any pain in the part, but, as he was evidently very unwell, he was taken into the hospital forthwith. The patient had contracted syphilis in India twelve years ago, had suffered from cholera in India three years ago, and had also suffered from dysentery whilst in China recently. During several recent voyages the patient, together with others of the crew, partook frequently of partially cooked meat, especially the so-called frozen mutton. His illness commenced about three weeks ago, after a considerable debauch, by general pains all over the abdomen, which on subsiding left a feeling of uneasiness at the upper part of the abdomen. Then it was that the tumour was first noticed. He stated that the tumour got larger for about a fortnight, and then seemed to cease enlarging. The temperature on the evening of the 15th was 100°, being down to normal the next morning, and running up to 101° in the evening again.

The patient was seen by Dr. Ralfe on the 17th. The tumour was larger and more doughy to the touch, and the fluctuation less distinct than on the previous Monday. Mr. MacCarthy was called in consultation, and it was decided to make an exploratory puncture. The patient being anæsthetised with ether, Mr. MacCarthy proceeded to puncture the tumour at about its centre with a trocar and cannula, with the result of pus being found. Then, without the use of the carbolic spray, a free opening was made into the abscess and enlarged with the finger, allowing about a pint and a half or two pints of laudable pus tinged with blood to escape. On inserting the finger, an extensive cavity was found extending deeply downwards, excavating the whole left lobe of the liver. The cavity was then washed out with a weak carbolic solution and a large drainage-tube inserted. The orifice was dressed with iodoform, with a wood-wool pad and antiseptic gauze.

Nov. 18th.—Temperature last night 101°. The patient felt no ill effects from the operation beyond a slight headache. Wound dressed this morning, and the cavity syringed out with carbolic solution. A considerable amount of discharge had taken place. Temperature 99°; pulse 80. Patient quite comfortable; no pain.

20th.—Discharge still plentiful, but diminishing. The drainage-tube, which was level with the surface of the

Digitized by Google

abdomen, now protrudes half an inch from the wound. Temperature normal; pulse 78.

25th.—The temperature went up to 100° last night, but is normal this morning; pulse 82. The tube in the cavity is now about an inch and a half long. Discharge much less. General health much improved. Diet increased. No pain.

27th.—Large drainage-tube came out in the night, and so this morning a smaller one was substituted. Very little pus washed out. Temperature 97°; pulse 80.

Dec. 4th.—There has been no pus washed out for two or three days, and so syringing is discontinued. A very small piece of drainage-tube is now left in the cavity. The opening of the cavity is too small to admit even the tip of the little finger, but the probe goes in about an inch and a quarter. Wound dressed as usual. Temperature 97·5°; pulse 80. Patient gets up.

7th.—Tube removed entirely; no discharge. Probe goes in about an inch. No pain, only a tickling, itching sensation round lips of wound.

13th.—Wound dressed with small piece of padding and iodoform; is healing rapidly. Patient eats well and is up all day. Has no pain whatever.

17th.—Patient discharged. Wound quite healed up. He was looking much better than when he came in, and had gained several pounds in weight.

The only drug treatment the patient had was a quinine mixture until the operation and slight laxatives regularly afterwards.

Remarks.—The clinical interest in this case was the painless character of the swelling, and the very slight degree of pyrexia attending this large and rapidly formed collection of pus. The patient declared that he had never experienced a rigor and did not sweat, and it was not till his admission to the hospital that a slight rise of temperature at night was noticed. This, taken with the history of the patient having eaten for some time raw meat, led to a suspicion that the swelling might prove to be a hydatid cyst undergoing suppuration, but the peculiar doughy infiltration of the integuments over the tumour was considered decisive of the abscess being hepatic. The case also illustrates the advantage of a large opening and drainage-tube, the patient being discharged cured within a month of the operation. In a previous case, where the incision was made between the eighth and ninth ribs, owing to narrowness of the intercostal space only a small drainage-tube could be introduced. Considerable difficulty was experienced in keeping the tube free, and pus was constantly re-collecting in the abscess, so that the patient was in the hospital some months before the abscess closed up. As regards the comparative results obtained by aspiration and free drainage respectively, Dr. Ralfe has had seven cases of hepatic abscess under observation. In the first three aspiration was relied on, and of these all have died. Of four cases treated by incision and drainage three have made a complete recovery; the fourth case recovered from the operation, but as soon as the abscess closed tubercular phthisis developed, which rapidly proved fatal.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

TWO CASES ILLUSTRATING THE TREATMENT OF THE DEFORMITY FOLLOWING TUBERCULAR DISEASE OF THE KNEE-JOINT.

(Under the care of Mr. BILTON POLLARD.)

For the notes of the following cases we are indebted to Mr. H. Downes, house-surgeon.

CASE 1. *Tibia flexed and displaced backwards; joint opened by division of the patella; anterior crucial ligament divided and limb straightened; joint healed under one dressing.*—Eliza P——, aged seven years, was admitted on Sept. 27th, 1886. Her father and two of her brothers had died from consumption. The disease of her knee began when she was two years of age. Plaster-of-Paris bandages were applied for a few months, and then for a period of eighteen months nothing more was done. The leg became drawn up and shortened. Two years ago an operation was performed on the knee, and the child returned home with discharging sinuses. For the last seven months the knee had been quite sound, but the deformity had been steadily increasing. On admission the child was well nourished, and presented no signs of disease. There were scars of old sinuses on the front and inner side of the right knee. The joint was flexed almost to a right angle, and so firmly fixed that no extension or flexion movements could be made. The tibia was displaced backwards considerably, and the leg was much wasted.

On Oct. 8th an incision was made across the front of the knee, and the joint opened by sawing across the patella. It was found impossible to straighten the limb owing to the tibia being held backwards by means of a mass of fibrous bands taking the direction of the anterior crucial ligaments. These bands were divided, and then it was possible to bring the tibia forwards; but the limb could not be quite straightened owing to the interval between the condyles being so filled up as to prevent the somewhat enlarged spine of the tibia riding forwards into it. This interval was deepened sufficiently to accommodate the spine, and then the leg was brought forwards into a line with the femur. There were no visible signs of recent disease in the joint. A few vascular points were seen and ligatured, but the tourniquet was not removed until the dressing had been applied. The two halves of the patella were united by a silver wire suture. The middle portion of the skin wound was sutured, but both ends of the wound were left open for drainage. No tube was employed. The wound was dusted with iodoform, and a dressing of salicylic wool was applied and firmly bandaged on. A piece of galvanised iron was placed behind the knee in the middle of the wool as a support to the joint. The limb was raised to a right angle with the body for a few hours. The spray was used during the operation, and the strictest attention was paid to antiseptic details. The temperature reached 100·6° F. on the second day after the operation; it then fell to the normal and remained so. No blood or discharge showed through the dressing, and there was no need to change it, but on the twenty-second day after the operation this was done to remove the stitches. The wound was healed except at a small spot opposite the wire in the patella. Three weeks later the wire was removed from the patella, and a week after that the limb was put up in plaster-of-Paris and the patient was discharged. She was seen six weeks later. The limb was straight and slight movement at the knee was possible. The patella was soundly united and freely movable at the condyles of the femur.

CASE 2. *Left leg flexed and abducted at the knee and ankylosed; joint excised and bones wired; joint healed under one dressing.*—Annie P——, aged eight years, was admitted on Aug. 31st, 1886. Her father and grandfather died of consumption. The disease of the knee commenced after a fall when the patient was fifteen months old. The knee had never suppurated, but it got much deformed and almost prevented the patient from walking. The child had been twice in the hospital during the year. Weight extension and forcible movement under chloroform failed to reduce the deformity.

On admission, the patient could only hobble about a little; the knee was flexed to an angle of 45° from the extended position; the leg was abducted and rotated outwards at the knee; the joint was firmly ankylosed, and the patella was fixed to the external condyle.

On Oct. 2nd the joint was opened by a transverse cut across the patella; the patella was firmly ankylosed to the external condyle, from which it was freed by a vertical saw-cut. The greater part of the external condyle had been destroyed, and as it was found impossible after the division of fibrous bands to bring the leg straight, a slice of bone was removed from the lower end of the femur, and a very thin layer was removed from the tibia; a few vascular points were tied. The limb was put straight, and the patella was united by a wire to the front of the femur, the femur and tibia being united by a second wire. The rest of the treatment was identical with that described in the first case. The temperature remained normal throughout. On the second day after the operation a spot of blood appeared through the wool, so a layer of the latter was removed and a fresh layer applied, but the wound was not exposed. Four weeks after the operation the dressing was removed and the wound was found healed in its entire length. The dressing was stained with blood only, and was perfectly dry. Three weeks later the limb was put up in plaster-of-Paris and the patient was discharged. The patient was seen a month later; the limb was soundly healed, but there was a small sore opposite the wire suture which united the tibia to the femur. This was removed, and after a week the wound was healed.

Remarks by Mr. POLLARD.—The first case appears to me of much interest and importance. It is well known that after strumous disease of the knee, when the tibia is dis-

Digitized by Google

placed backwards, it is useless to attempt to straighten the joint until the tibia has been carried forwards, for unless this precaution be taken, either the backward displacement will be increased or the tibia will give way at the upper epiphysial line. To Mr. Beck's teaching at University College I owe the knowledge that the cause of the difficulty in straightening the limb in such cases is the shortened anterior crucial ligament combined with other adventitious bands, and in this case I was able to demonstrate the correctness of that teaching, and to show that the deformity might be remedied after dividing these bands without removing any bone, and subsequently without impairing the growth of the limb. In the second case the external condyle of the femur was so destroyed that it was impossible to straighten the limb without performing an excision. This I regret greatly, and I would not have done it if any other means would have succeeded, for the growth of the bone will be impaired thereby. The cases are good examples of what can be achieved by aseptic surgery—primary union—under a single dressing without tubes. I do not know that the complete method of dressing detailed in the first case has as yet been published, but I claim no credit for it; I owe it likewise to Mr. Beck, and my cases are only instances of the success which has attended it equally in his hands as well as those of other surgeons. For such operations as those described I prefer Volkmann's method of dividing the patella, for I should anticipate firmer union of a wired patella than of a sutured ligament.

ST. VINCENT'S HOSPITAL, DUBLIN.

TWO CASES OF ABSCESS EVACUATED WITHOUT ANY RESULTING DISFIGUREMENT; REMARKS.

(Under the care of Dr. QUINLAN).

For the report of these cases we are indebted to Mr. M. C. O'Gorman, resident pupil.

CASE 1.—C. B——, aged seventeen, a messenger, was admitted on Oct. 12th, suffering from a large swelling occupying the whole right submaxillary space, and in which deep-seated fluctuation could be detected. On the 15th, the purulent matter being apparently half an inch from the surface, a silver wire was introduced in a horizontal direction, beginning in the healthy tissue to the right of the abscess, passing through it, and coming out about half an inch on the inner side of it. Lint wetted in spirit lotion was applied to the external surface. On the next day purulent matter was coming out at both openings; but after a few days it was evident that the lower part of the abscess was working towards the surface. This arose from the circumstance that the lower part of the abscess extended down the neck much further than was at first supposed, and in consequence a "pocket" of purulent matter pressed upon the tissues and produced absorption of them. As the skin was actually beginning to thin, another wire was on the 20th introduced through the external opening of the original wire, passed through the "pocket" above described, and brought out well below it. In a few hours the pus began to discharge through the lower opening, and the tendency to "point" at once ceased. The discharge became gradually thinner, the abscess being carefully evacuated by pressure with a tampon of soft cloth in the morning, mid-day, and evening. On the 25th the discharge from the openings of the original wire having entirely ceased, it was removed, and the evacuation process through the secondary wire carefully continued. On Nov. 22nd all discharge ceased, the swelling was much reduced, and the redness of the skin greatly lessened. On Nov. 7th the secondary wire was removed, and on the 10th the openings had healed up. On Nov. 16th the patient was discharged. There was slight swelling and induration on the site of the abscess, and very little redness of the skin on the spot where it had threatened to point. Three red points showed the sites of the entrance and exit of the wires. On Nov. 22nd the boy was seen, and all traces of the abscess were rapidly disappearing, there being no disfigurement whatever.

CASE 2.—M. H——, aged thirty-nine, a healthy, well-nourished woman, the mother of eight children, had been confined of her last child, a girl, on June 2nd. A month after, a swelling appeared in the left iliac fossa over Poupart's ligament, accompanied with great pain, gathering up of the left thigh, and stooping of the body. She became gradually unable to make the slightest exertion, and was at last obliged to take to her bed. She was admitted on Aug. 19th. She was treated with hot poppy fomentations and linseed poultices, together with hypodermic injections of morphia, to keep down the pain, which was extreme; quinine and nourishing diet were given to support her strength, which was very much reduced. Suppuration took place, so that on Aug. 25th the purulent matter was within half an inch of the surface. Two silver wires were introduced through the abscess—one in a direction parallel to Poupart's ligament, and the other at right angles thereto. The matter gradually discharged itself along these wire setons, a dressing of calico steeped in spirit lotion being kept continuously applied. The pain and swelling steadily subsided, and the discharge, which was profuse, became less of a purulent and more of a sanious character. On Sept. 10th it had ceased for some days, and one of the wires was withdrawn. After an interval of three days the second wire was withdrawn, and the openings closed. On the 20th she was able to walk without stooping, contraction of the leg, or pain; and on the 28th she was discharged, cured, and without any mark over the site of the abscess, except four red pinhole openings corresponding to the entries and exits of the wires.

Remarks by Dr. QUINLAN.—In both these cases large abscesses were evacuated without the production of any external mark or disfigurement. In the second case the situation of the abscess in the groin rendered this a point of little consequence, although this case clearly shows how disfigurement can be avoided in abscesses of the neck and face, where the avoidance of marking or deformity is most desirable, especially in the case of females. The treatment is dependent upon the early introduction of the wire, upon the avoidance of poultices (which tend to relax the capillaries of the skin) during the wire process, and upon the application of spirit lotion, which cools the surface, keeps down inflammation, and hardens the skin. This method is superior to aspiration, which causes too many punctures, and has not the same power of keeping the sac of the abscess empty by the drainage of the matter, whether purulent or sanious, as fast as it is secreted. This constant drainage, which is greatly aided by the use of the flat tampon of old soft calico, causes the sac of the abscess to collapse, and removes all pressure and consequent chance of absorption from the skin. The red wire openings left after the operation are small cicatrices, not larger than the head of a full-sized pin. These undergo cicatricial contraction and disappear. In the case of Miss O. D——, recorded in THE LANCET some years ago, they cannot now be detected, even by the aid of a lens.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Surgical Treatment of Hydatids of the Liver.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. The whole of the evening was occupied by the discussion of Mr. Barwell's paper.

Mr. RICHARD BARWELL read a paper on widely incising, by a two-stage method, Hydatids of the Liver. Hydatids of the liver may be treated surgically by (1) puncture with a small trocar, (2) evacuation with a large persistent opening, and (3) electrolysis. This last has not commended itself to the judgment of the profession. The author recommends that the first method should always be primarily resorted to, chiefly because it sometimes is curative—viz., in cases of single barren cyst; but in a large proportion of cases there are numerous daughter or secondary cysts, and then the tumours frequently recur. Under such circumstances the most efficacious treatment is by keeping a large opening patent for some time. The object of the paper was to point out the safest way of making such an opening. After discussing certain other methods, it was shown that incising the abdominal parietes first, then stitching to them the cyst or its surroundings, and finally cutting into the tumour after a few days, was regarded as a very safe and efficacious procedure. The author recommended certain precautions to be taken when the cyst wall appeared so thin that a needle puncture might cause effusion of hydatid fluid into the peritoneum. Some modifications introduced with a view to meet special circumstances were discussed. The case of a young

Digitized by Google

woman who had a hydatid of the liver which had been punctured eight times, and on whom the author performed the above mentioned operation, was related. After a time eighteen hydatids and the wall of a large mother cyst were passed from the wound. There was an absence of peritoneal symptoms, and the patient made an easy recovery.

Mr. W. HAWARD considered that the character of the contents of the hydatid cysts should determine the nature of the operation. Doubtless a free opening would be required if the contents were thick and compounded of daughter cysts. He criticised Mr. Barwell's method, and thought that the potassa fusa caustic was to be selected, rather than the one which Mr. Barwell advised. His remarks were illustrated by cases. In one instance a second cyst was found bulging into the first, which had been emptied. The second one was also opened through the first, but still the patient did not recover, and finally died with lardaceous disease. Hydatids were found in the omentum and spleen, and a suppurating cyst in the back of the liver, which was doubtless the cause of the continued illness and lardaceous disease. Altogether the method of gradual perforation of the abdominal wall, so as to secure proper peritoneal adhesions, was to be preferred to other methods.

Mr. HOWARD MARSH had successfully practised the operation recommended by Mr. Barwell in one case recently. The sutures had to be passed into the substance of the liver because the hepatic peritoneum was so thin. The suppurating hydatid cyst was incised four days afterwards. In a case of suppurating hydatid cysts of the liver in a little child, an abdominal section was made without attempting to secure adhesion between the liver and abdominal wall. The result was satisfactory, and the case not complicated by the extravasation of the contents of the cysts into the peritoneal cavity.

Mr. HARRISON CRIPPS considered that the free incision enabled the surgeon to deal with multiple cysts, which, in his experience, were frequent complications of hydatids of the liver. A case illustrating the advantage of a free incision was mentioned. In this instance special precautions with a view to obtaining adhesions were not used. A second cyst was completely emptied through the wall of the first cyst, which had also been completely evacuated. The results were perfectly satisfactory.

Sir DYCE DUCKWORTH had seen good results after all the methods of treatment for hepatic hydatids. He was doubtful of the excellency of the advice that all the contents of the cyst should be evacuated at the surgical operation. It was still a point for the surgeons to decide whether the cysts should be completely cleared out, and whether antiseptic injections should be practised.

Mr. WALSHAM remarked that surgical treatment of hydatid cysts was not always of a harmless nature. A few cases of sudden death, even from aspiration, had been recorded. Perhaps this was due sometimes to hydatid fluid escaping into the venous circulation. He could not but think that an incision four inches long would be attended with some danger. In several cases of the kind he had made the incision from an inch to an inch and a half in length, and found this size ample for all purposes. There was but little fear of pus or hydatid fluid escaping into the peritoneal cavity, and he thought that excellent results could be obtained without the surgeon first endeavouring to secure adhesions of the cyst to the abdominal wall. After evacuation of the contents the cysts should be well syringed with carbolic acid solution, and then powdered with iodoform. In his own practice the wounds healed under this treatment with the best possible results.—Dr. ANGEL MONEY said that a continental surgeon was operating by abdominal section on a case of hydatid of the liver when the patient suddenly fainted and died. A daughter cyst must have escaped from the liver and entered into the hepatic vein, for one was found free in the right auricle of the heart.

Mr. A. PEARCE GOULD thought that aspiration should be tried first in all cases. It was still an open question as to what was the best means to be adopted even in aspiration. Should the surgeon remove all the hydatid fluid obtainable, or only a small quantity? Perhaps the latter method was the safer. In one case that had been under the care of Dr. C. Y. Biss, in a woman aged forty, Mr. Gould made an incision through the right linea semilunaris, when peritoneal adhesions were found and four quarts of pus and hydatid cysts evacuated. The patient began retching, and the omentum protruded at the lower part of the wound. In the omentum abortive hydatid cysts were seen, but the omentum was easily returned and the sinus eventually closed. In a second case there was a very large hepatic tumour, from which reddish serous fluid, without hooklets, was drawn off. After incision two pints of fluid flowed out, and a large quantity of solid material was discovered. Some days later much of this material was scraped away, and some bleeding resulted. The case had now almost completely recovered. He was strongly in favour of the knife as against caustics. He did not think it was necessary to stitch the wall of the cyst to the abdominal wall before opening the tumour.

Mr. HENRY MORRIS supposed that the chief point for discussion in the paper was the necessity or not of a double operation. In a work of Dr. W. Thompson, published in 1841, on diseases of the liver and biliary passages, four methods of treatment were fairly stated. Some quotations were made by Mr. Morris from an article published in the *Madras Quarterly Medical Journal* for 1839 by an Indian surgeon, in which the opinion was expressed that there was not much danger of effusion into the peritoneal cavity in opening abscesses of the liver. The plan of attaching the cyst to the abdominal wall was perhaps associated with that of gastrostomy and colotomy, but the procedures in the three cases were altogether different; for in the two latter operations a mobile and contracting organ had to be dealt with. In hydatids of the liver it was necessary to obtain a sufficiently large opening to allow of the escape of bulky contents. It was not difficult to secure coaptation of the cyst to the abdominal wall, and thus to prevent the escape of fluid into the peritoneum. Manipulations were also possible by which this coaptation could be secured at the time of operation. He thought that there was no necessity for a division of the operation into two stages. He could not think the procedure of Mr. Harrison Cripps—of removing the entire mother sac—an advisable one. Once, when tempted to perform this, he had in his recollection the case recorded by Dr. Bright, in which the stripping of the parent membrane from the adventitious coat was followed by hæmorrhage that nothing succeeded in stopping. Once also a boy was run over and died. It was found at the necropsy that a hydatid cyst of the liver had become detached from its adventitious capsule, with consequent fatal extravasation of blood between the true and the false sac of the hydatid. The surgeon should, in his opinion, empty as much of the fluid and daughter cysts as would come away without using force, but he should not attempt to remove the parent sac at the time of operation. He had never resorted to irrigation, but aseptic drainage-tubes should be used. The indiscriminate use of iodoform in the cyst might be followed by disagreeable delirium and perhaps even death.—Mr. BARWELL said that he could supply the sequel to the case narrated in the paper. A small but long sinus persisted for some time, but had recently completely healed. He had a dread of filling a large cavity with iodoform; symptoms of blood-poisoning had been known to occur after such free dressings with this powerful antiseptic.

MEDICAL SOCIETY OF LONDON.

Hunterian Chancre of Lower Lip.—Plastic Operations for Ectropion and Contraction of Face.—Excision of Elbow.—Nævus of Hand.—Early Colotomy.—Floating Abdominal Tumour.—Pharyngo-laryngeal Stenosis.

A CLINICAL MEETING of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. G. R. TURNER showed a living specimen of Hunterian chancre on the lower lip complicated by a mushroom-like growth on the chin. The man had injured his lip five months ago, and two months and a half ago the site of injury took on morbid action. There had probably been simultaneous inoculation at two places, and this was perhaps the chief interest of the case. Syphilitic sores were found on the penis, and a suppurating bubo in the left groin, also an eruption on the arms.—The PRESIDENT thought the high probability was that the inoculation had been accidentally effected with the man's own fingers.—Mr. BLOXAM remarked on the occurrence of two chancres on the lip in close proximity. He had several times seen three and four hard chancres in one individual at the Lock Hospital. They affected any position, such as the upper and lower eyelids, side of the nose, armpit, nipple, abdomen, umbilicus, arms, and back.—Mr. HARRISON CRIPPS had observed fourteen cases of Hunterian

Digitized by Google

chancres of unusual situation during the past year. In one case of chancre of the eyelid, in a woman aged seventy years, it seems that the grandchild was suffering from secondary syphilis, and the woman averred that she had obtained her sore from the child. These unusual sores might not show any induration when occurring in the skin; but those attacking the lips sometimes caused the submaxillary glands to enlarge so much as to suggest mumps.

Mr. DAVIES-COLLEY exhibited a case of Ectropion following necrosis of the superior maxilla in a boy aged six. He showed the case as an example of a new form of operative procedure for the relief of a severe case of ectropion. The lower eyelid exhibited a granulating surface of the palpebral conjunctiva, and was exposed over an extent of three-eighths of an inch at least, from above downwards. The bone beneath the sinus was bare, but not loose. The edges of the tarsal cartilage were pared over the outer two-thirds of their extent, and after freeing the lower eyelid by an incision three-quarters of an inch long, made parallel to it and a quarter of an inch below its free border, the eyelids were sutured together. Three-fifths of the palpebral aperture were closed. Nine months after this operation the sinus had healed up, but the contraction of the parts had considerably drawn down the upper eyelid. The union was divided, and the eversion of the eyelid was seen to be as bad as ever. A year after the first a further plastic operation was performed: a triangular flap of skin two inches long was taken from the left temple just behind the external angular process, and fixed on the gaping incision which had been again made below the lower eyelid. This flap healed fairly well, but the upper eyelid was still drawn down, and the palpebral aperture was very small. To overcome this defect, Mr. Davies Colley divided the upper eyelid and converted that portion of it which had for some time occupied the position of the lower eyelid into a substitute for it. The result was very satisfactory. The boy had good sight and could close the eye. The hairs of the upper eyelid still remained in what was now the lower border of the lower eyelid.—Mr. BRUDENELL CARTER congratulated Mr. Davies Colley on the success of the treatment.

Mr. WALTER PYE showed a Nævus of the Left Hand in a girl aged seven years, in whom there was a clear and definite history of a maternal impression.

Mr. ASTLEY BLOXAM exhibited a case of plastic operation for Contraction following Ulceration of the Face. In 1879 the patient had ulceration of the entire face as high as a line drawn transversely across the face at the level of the infra-orbital ridges. The nose was completely eaten away in process of time. The ulceration was probably due to lupus, though some contended that syphilis was the cause. In December, 1886, the mouth was represented by an opening half an inch in transverse and a quarter of an inch in vertical diameter. On Jan. 13th Mr. Bloxam operated as follows: A tube was placed into the orifices representing the nostrils, and the tongue was secured by a piece of string passed through the lip. An incision was then made through the cheek on either side, and the mucous membrane turned down over the lower lip and fastened to the incision in the skin by horsehair sutures close together. The skin of the upper lip was then stitched to the mucous membrane with horsehair. The result was very satisfactory.—Mr. BRUDENELL CARTER had operated on a somewhat similar case with a good result.

Mr. WALTER PYE showed a case of Excision of the Elbow in a boy aged six, in whom he tried to perform a partial excision, leaving the lesser sigmoid cavity of the ulna; but this had to be removed after five months had passed. The part left seemed to be typically healthy. The case went to show that complete excision was most necessary in order to obtain a perfect result.

Mr. HARRISON CRIPPS showed a case of Colotomy for Carcinoma of the Sigmoid Flexure in a woman aged forty. The opening of the artificial anus was of a valvular nature, and the patient had considerable power over defecation. The operation had relieved distress and diarrhœa, and probably retarded the growth of the disease. It was important to obtain primary union between the skin and mucous membrane. The operation was in this case very beneficial to the patient.—The PRESIDENT, Mr. J. H. MORGAN, and Mr. BLOXAM joined in the discussion. Mr. H. CRIPPS, in reply, thought it was most important to get the bowel thoroughly emptied before opening it, if primary union was desired.

Mr. ISAMBARD OWEN described a case of Floating Abdominal Tumour in a woman aged seventy-six. It was situate in the epigastric and umbilical regions, and reached beyond these bounds, but was not apparently connected with either the liver or spleen.—Dr. W. H. DICKINSON thought it was a floating kidney.—Dr. C. T. WILLIAMS considered that the splenic relations of the tumour were not absolutely negatived; the tumour might be omental and benignant.

Dr. GILBART SMITH showed a case of Pharyngeal Stenosis of peculiar funnel shape; the epiglottis was much contracted and the cricoid cartilage thickened. The larynx seemed to have received a sort of twist. There was no doubt that the man had had syphilis, though he attributed the laryngeal state to accident.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society on Jan. 7th, Dr. Alderson, President, in the chair, the following communications were made:—

Dr. BLENKINSOP read a paper upon Phthisis and its Treatment.

The Etiology of Phthisis and its Treatment from a Hygienic Standpoint.—Dr. SEYMOUR TAYLOR read a paper under this title. Phthisis he considered a condition or symptom having several causations—inflammatory, fibrous, tubercular, or otherwise. The tubercular form might be described as bacillus phthisis, or, owing to Koch's connexion with the tubercule bacillus, the disease might be called Koch's phthisis. In his experience the bacillus tuberculosis was always present in tubercular phthisis. Tuberculosis, like cancer, may vary in its virulence. In some it may be general in its distribution; in others it may be quite a local process. It is not singular in its behaviour. It seems to attack some localities from choice. It selects certain families or constitutions, apparently by preference, and not by accident. The author then discussed the arguments which had been advanced against the infective theory of tuberculosis, and said that other factors were necessary for a man to contract the disease than the mere contact of the bacillus; while, whatever the gate of infection might be (mucous or otherwise), an abnormal condition of the points of contact was a certain factor in the production of the disease. The blood contained bacilli after inoculation, and, as in enteric fever, a relapse may be occasioned by re-inoculation from an infected patch of ulceration; so it may be the case with the extension of tubercular ulcer on the tonsil, or buccal cavity, or from strumous glands containing bacilli; indeed, it is possible by inhalation to account for the multiple tubercular lesions which are met with in the lungs. The author then sketched briefly the life history of a tubercular patch, and discussed the origin of the giant cells. He concluded by epitomising the causes which in his opinion rendered phthisis so virulent amongst us, and said that our cold damp climate, by favouring the prevalence of catarrh of the respiratory apparatus, was directly responsible for a condition which allowed the tubercular parasite to flourish.

The Operative Treatment of Intercurrent Disease in Tubercular Patients.—Mr. BRUCE CLARKE read a paper on this subject. After briefly discussing the nature of tuberculosis and its dependence on a specific bacillus, the author proceeded to show that it was almost impossible to remove by a surgical operation the whole of the bacilli that had found their way into the body. The local manifestation was all that could be got at. It was clear, therefore, that an operation could only aim at removing a growth which was causing so much constitutional disturbance as to prevent the recuperative powers of the patient and the physician's remedies from exercising a due influence on the course of the intercurrent disease. After relating several cases of his own and of other surgeons in which such operative treatment had been practised with more or less favourable results, and after showing that such cases healed with success and ease, the author concluded by asserting that surgical interference was only justifiable when all attempts at cure without the knife had been tried and found wanting.—Dr. THOROWGOOD, in the course of some remarks, said that a depressed state of the nervous system was an especial factor in the causation of phthisis.—The PRESIDENT said that a dry soil was an important preventive of phthisis. In the second decade men

Digitized by Google

were much more prone to the disease than women.—Dr. THUDICHUM observed that there was no climate in the world which was free from phthisis. He thought the Koumiss cure advocated by the Russians was of no real use. It was remarkable that since Koch's discovery of the bacillus phthisis had increased all over the world.—Messrs. H. H. Taylor, Lloyd, Benham, and Dunn continued the discussion; and Drs. Blenkinsop, Seymour Taylor, and Mr. Bruce Clarke respectively replied.

Dr. P. S. ABRAHAM showed a selection of sections of Tubercular Organs in man and the lower animals, and specimens of the Tubercle Bacillus.

Messrs. WRIGHT and Co., of New Bond-street, exhibited a large collection of Instruments, Sprays, and Inhalers.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Preventive Inoculations.

A MEETING of this Society was held on Jan. 12th, at which a paper on the above subject was read by EDWARD F. WILLOUGHBY, M.B.

In opening this paper, which was, he said, in some sense a continuation of one he read last May on the Variolæ of Man and Beast, the author called attention to two characters by which a large class of diseases were distinguished from all others—viz., the spontaneous extinction of the morbid process within a limited, often definite, time, and the immunity against subsequent infection, more or less lasting and complete, which followed one attack. The two phenomena were doubtless closely counected, but till lately no rational explanation had been even proposed. On the latter, however, rested the whole idea of protective inoculations, and it was of the utmost importance that clear and correct conceptions of their nature and relations should take the place of the confused notions that at present prevailed, not only out of, but even within, the profession. The first condition of a preventive inoculation was that the virus used should be derived directly or indirectly from the disease it was intended to avert: "Diseases distinct but antagonistic," to use Mr. Fleming's expression, were unknown to pathologists. Cow-pox protected against small-pox only, because it was small-pox modified by having passed through the cow. The second condition was that the disease must be one that does not recur. All non-recurring diseases were, or were presumably, bacterial; but the converse did not hold good, for some bacterial diseases ran on indefinitely, as tuberculosis and septicæmia; and others, as diphtheria, typhoid, and cholera, conferred no immunity. Consequently, there could in such be no such thing as preventive inoculation, while inoculations of one disease in the hope of averting another were worse than useless. Preventive inoculations might be divided into four or five orders—viz., methods of (1) *Inoculation*, (2) *Vaccination*, (3) *Attenuation*, and (4) what for want of a better term he would call *Neutralisation*. The first and second had as yet been applied only in the case of the varioloid diseases, and he would repeat from his former paper the principles on which they were based. They were: 1. One attack of variola, of the kind proper to any animal, protects the individual against infection by, or inoculation of, the same. 2. Inoculation of any animal with the virus of its own variola produces a milder form of the same disease, but affords a protection similar to that conferred by an attack contracted by ordinary infection. (This is the method of inoculation, properly so called.) 3. Any variola inoculated in an animal other than that whose proper variola it is gives rise to a peculiarly modified form of the disease, attended by little constitutional disturbance, merely local eruption, and no danger to life, such modified disease being no longer communicable to any other animal of the same or of different species, except by direct inoculation (cow-pox is such a modified form of small-pox). 4. This modified disease affords a considerable degree of immunity against infection by any means whatever with the variola whence it was derived, either to the animals whose variola was the original source of it, or to others capable of being infected in any way thereby. (This is vaccination, properly so called.) The first method, or that of inoculation, is open to the grave objection that, however great the immunity conferred and small the risk incurred by the individual, the disease is unchanged and infectious. Jenner's operation is as yet the only instance of the application of the second method, though there is no reason why some animal should not be found to play for the sheep the part that the cow does for man, and it seems probable from Dr. Klein's experiments that the disease at the farm at Hendon, which he would call Cameron's disease, stood in precisely the same relation to scarlatina as cow-pox did to small-pox, and might possibly be employed in the same way. If so, it would be a vaccination in every sense. The third class comprised the so-called attenuations of M. Pasteur, in which it was alleged that the cultivation of the bacilli in artificial media under certain conditions lessened their virulence, so that inoculation with them produced, as in the first method, a milder form of the disease. To minimise the risk, M. Pasteur generally used attenuations of two degrees of virulence, the weaker affording protection against the stronger, and this against the disease itself. This method was open to the same objections as the first, and also to the more serious one, that, it being impossible to standardise the attenuations, they sometimes failed to confer any protection, and at others caused the death of the animal. For this reason they could never be used in the case of man, and except under special circumstances could not be recommended even for domestic animals. The fifth class was represented by Pasteur's practice as regards rabies and hydrophobia, on which he did not yet feel in a position to express a decided opinion. But it was to the fourth method that he wished to to call the attention of the meeting. It consisted in the inoculation of the products of the development of the bacilli without the bacilli themselves. It was well known that all low forms of life, such as those concerned in fermentation, putrefaction, &c., as well as bacilli secreted or caused to be formed in and from the fluids in which they grow, contain chemical products, and that in some cases, as alcoholic fermentation, when these accumulated to a certain point the further development of the organisms was arrested, and doubtless something analogous to this occurred, and to some extent explained the spontaneous extinction of the febrile process, in the so-called zymotic diseases, though it would not of itself explain the subsequent immunity, since such products could not but be eliminated in the course of a few weeks at the longest. However, Dr. Salmon, of the Bureau of Animal Industry in connexion with the Agricultural Department of the United States, had found that, while pigeons were peculiarly susceptible to the poison of swine plague, he could by employing inoculations of sterilised cultivations of the bacilli in artificial media render them perfectly insusceptible. After some more or less successful experiments he performed a series which gave the most decisive results. Culture fluids heated to 140° F. for several hours were so far sterilised that they failed to develop in fresh gelatine solutions. And four pigeons inoculated two or three times at intervals of a fortnight or more with such sterilised fluids were but slightly indisposed after each operation. Finally these birds, together with one that had received a much smaller dose seven weeks previously, and a control bird inoculated with the gelatine only, were each inoculated with '75 cc. of a virulent culture of swine plague, a dose that had invariably proved fatal to others. The results were most remarkable: the control bird died in twenty-four hours; that which had received the insufficient dose fifty days previously died in forty-eight hours; while the other four birds were absolutely unaffected. Cultivations from the blood of the two that died developed the specific bacilli in abundance. Dr. Salmon, therefore, inferred that the products of the development of the bacilli of any such disease so modified the constitution of the bioplasm of the tissues as to render it incapable of affording a pabulum for the bacilli, and, if they did not cause the death of the animal, led to the cessation of the morbid process; and, secondly, that since cells to which a special character had once been imparted tend, as in the case of carcinomata and other neoplasms, to transmit it to those to which they gave rise in the act of proliferation, this inability to support the growth of the particular bacillus might persist for many years; but that, since they might tend to revert to their original character, the individual might sooner or later become again susceptible. That such was the case was well known, as also that in some persons the insusceptibility was so soon lost as to be practically unattained, and that very mild attacks, like that of the pigeon that had received the smallest dose, failed to afford appreciable protection. This method, Dr. Willoughby thought,

Digitized by Google

promised results of incalculable importance, and to be of the widest application to the diseases of man and beast. It was merely necessary to identify the specific bacillus to find a suitable medium for their cultivation and to determine their thermal death-point, or to remove them by the Pasteur-Chamberland filter. It was entirely free from the objections to which inoculations and attenuations were open, the phenomena induced being those of a poison, whatever it be, actually antagonistic to that of the disease. Mr. Willoughby urged that investigations on these lines should be at once undertaken in respect of all infectious diseases of cattle, and that there was one human disease—yellow fever—the fatality of which would fully justify, or rather demand, such an experiment, which might under circumstances of special exposure.

New Inventions.

NEW FLEXIBLE GLYCERINE RING PESSARY.

MESSRS. ARNOLD & SONS, of West Smithfield, have patented a new form of annular pessary, which is precisely similar to the ordinary indiarubber ring pessaries. Like these it contains a watch-spring, and is therefore of the same resistance; but instead of being covered with a piece of

thick indiarubber, it has first a coating of rubber around the watch-spring, and then a thin rubber case filled with glycerine. By this means the pessary is rendered beautifully soft; the glycerine, unlike air, never escapes; and the pessary is rendered much softer and easier of introduction.

HUTCHINGS'S FILTERING-PAPER.

In this paper (manufactured by G. J. Hutchings, Howard-street, Baltimore, U.S.) a coarse trellis-like gauze is embedded in the pulp, so that filters of quite exceptional strength can be made from it. Paper filtration is so excellent, and the material so cheap and clean, that we have no doubt this new article will be largely used. The inventor has already applied it to the household filtration of water, wine, and the like, and has made a coffeepot, which we have not seen, but which ought to be perfect. We think it was Jerrold who described English coffee as "perfectly palatial, standing in its own grounds," and the description is but too often true enough. Paper filtration is at once sufficiently accurate and quick to give a perfect infusion, as every chemist knows, while by successive additions of water all waste may be avoided.

THE NEW SEWERS OF THE PALACE OF WESTMINSTER.

The much-needed reconstruction of the main sewers of the Houses of Parliament has been carried out during the recess by Mr. Isaac Shone, the engineer in charge of the works, and on Tuesday last a select party, including representatives of some of the daily and weekly journals, were personally conducted by the engineer to view the alterations which have been made. Mr. Shone has issued an explanatory pamphlet, which to a certain extent is historical, and serves to show what an absolutely modern science is sanitation as carried out at present, and how crude were the attempts in this direction fifty years ago, even in the hands of men of genius with command of unlimited funds. The original sewer of the House, as laid by Sir Charles Barry in 1839, was a huge brick structure with a flat bottom, and having a fall of 1 in 923 towards Abingdon-street, where it emptied itself. It is needless to say that such a sewer as this, with no means of flushing, soon became little more than a nuisance. In consequence of the complaints of smells in the house a new sewer was constructed in 1846, with a narrow deeply curved invert, and with a fall of 1 in 215 towards Speaker's-green, close to which it emptied into a sewer in Bridge-street. This sewer, it will be observed, sloped in a direction opposite to the original one, and, being of better form and possessing ample means of flushing, served its purpose well till 1873. In this year the metropolitan low-level sewer was made, and the Palace sewer was connected with it, its bottom being 21 in. above the bottom of the metropolitan sewer, which was 7 ft. 9 in. in diameter. The average depth of sewage in the metropolitan sewer in dry weather has been about 42 in., 21 in. above the bottom of the Palace sewer. Thus there was always a head of sewage against the Palace outlet, and in wet weather, when the metropolitan sewer was full, the Palace sewage could not escape, and its sewer became a sort of storage reservoir for the metropolitan sewage, the pressure of which forced the sewer air back into the Palace. Thus the Palace of Westminster, especially of a night, when the gas was lighted, served the purpose of a partially exhausted chamber for sucking poison from the metropolitan sewers. Who can complain if the legislation of late years has not been all that could be desired? To remedy this state of things a committee was appointed in 1886, with Sir H. Roscoe, F.R.S., as chairman, and the recent improvements are owing to the labours of this committee. It is due to Mr. L. H. Isaacs, the Conservative member for Newington and Walworth, who is by profession an architect, to state that this gentleman twice performed the unpleasant and almost heroic task of traversing and inspecting the Palace sewer, and it was largely to his evidence and practical knowledge that the works just completed were undertaken. The plan of the new arrangement was supplied by Mr. John Phillips, and received the approval of Major Hector Tulloch, R.E., the Local Government Board inspector. There were originally about 122 subsidiary drain connexions with the main sewer, and these were formed at various levels on the top, bottom, and sides. The original main sewer was 10 ft. high and 3 ft. wide. The improvements which have been made are many of them in the direction of simplification, and will be easily understood. In the first place, the old brick sewers have been replaced by iron pipes. The chief tributary is 9 in. in diameter (in place of one 24 in. by 15 in.), and the main sewer is 12 in. instead of the dimensions above given. The outlet is into a manhole in Speaker's-green, and this is at a lower level than the bottom of the old sewer. Thus the gradients have been everywhere increased, and the rate of flow has been increased in the sewers from 1·11 feet per second (the rate in the main sewer of 1839) to a rate of 2·8 feet per second. This rate of flow is claimed to be what is called a self-cleansing velocity. Ample means for the automatic flushing of these new sewers has been provided in the shape of two Shone's automatic hydraulic flushing ejectors, which at regular intervals discharge a large volume of water through the sewer pipes. One of these flushing ejectors is at the head of the sewer near the Victoria Tower; the other is somewhere near the centre of the Palace. The sewage, falling to a lower level than formerly, is finally lifted some twelve feet, and is discharged into the metropolitan sewer at a level several feet above its bottom, so that the outlet of the Palace sewer is, except in times of flood, always above the level of the fluid in the metropolitan sewer, and has no head of sewage to oppose its outflow. The lifting of the Palace sewage into the metropolitan sewer is effected by means of Shone's pneumatic sewage ejectors. These machines are placed in a chamber beneath Speaker's-green. They consist of strong iron vessels, into which the sewage flows by gravitation. When they are filled a series of valves act automatically (1) to close the inlet, and (2) to admit a stream of compressed air, by which the sewage is driven through (3) the outlet. These ejectors have only to lift the sewage some twelve feet; but it is well known that in other places where they are in use (as, for example, at Warrington in Lancashire) this force is sufficient to drive the sewage more than

Digitized by Google

a mile. These ejectors have to be supplied with compressed air, which is provided by means of gas-engine air-compressors, which are in a chamber beneath the Palace, at some little distance from the chamber containing the ejectors. Between the metropolitan sewer and the Palace sewer a strong dam has been erected, which is perforated to admit the outlet pipe. The ejectors are fitted with automatic counters, so that every emptying of them is registered, and thus they will serve as sewage meters. These ejectors take, when Parliament is not sitting, about fifteen minutes to fill, but they discharge themselves always at about the same velocity of half a minute. Observations made while the machinery has been at work lead to the supposition that one gas-compressing engine and one pneumatic ejector will always be sufficient for the needs of the Palace. In order, however, to guard against all possible mishaps, there are four compressing engines and three ejectors. The Palace sewers take the rainfall which falls on the Palace area as well as the sewage, and therefore it is necessary to be ready for times of flood. If in times of flood sewage water accumulates in the outlet manhole, this will act on a float, which in its turn acts on Julius Sax's automatic electrical tidal water gauges, one of which is placed in the ejector chamber and another in the gas-engine room. These machines show the exact level of the water in the manhole, and tell of the necessity of putting a second or third ejector, or a second, third, or fourth gas-engine into operation. Again, if the whole of the new machinery should by some unforeseen accident become inoperative, a valve may be raised in the manhole, and the sewage will fall by gravitation into the metropolitan sewer, as was formerly the case. The new iron pipes are laid in the bed of the old sewers, which serve as convenient subways for workmen. The sewers are ventilated by means of the furnaces which exist in the basements of the Victoria and Clock Towers, and which are made by a very simple contrivance to draw fresh air through the pipes. The works have cost £11,000.

We must congratulate the members of both Houses upon the very important sanitary reform which has been effected by means of these works. There can be no doubt that the condition of the House will be immensely improved, and we think that much credit is due both to Sir H. Roscoe's committee and to Mr. Shone, who has so efficiently carried out the recommendations of that committee. The machinery for keeping the Palace sewers empty will, of course, be constantly supervised by skilled persons, who, it is evident, must always be present night and day, both in and out of session, in order that the proper supply of compressed air may be maintained, and the possible accident of sudden flood be grappled with. However, there is little likelihood of sewage accumulating in the Palace of Westminster in the future. Our legislators have shown themselves alive to the importance of "passing it on." Let us hope they will next turn their attention to the recipients of it, and take unhappy Barking and poor Father Thames into their kindly consideration.

THE CAMBRIDGE MEDICAL GRADUATES' CLUB AND LONDON MEDICAL DEGREES.

A SPECIAL meeting of the Cambridge Medical Graduates' Club was held in the rooms of the Medical Society of London on Thursday, Jan. 20th, "for the consideration of the pending questions with regard to degrees in medicine." The chair was taken by Dr. Dickinson of St. George's Hospital, one of the Vice-Presidents of the club. There was a poor attendance of members, only twenty-eight being present.

Sir Geo. Paget, K.C.B., moved the following resolution:—"That to establish a second university in London for the purpose of granting medical degrees is either unnecessary or unadvisable. That it is unnecessary, if the degrees are to be granted on a standard of acquirements equivalent to those of the existing University of London. That it is unadvisable, if they are to be granted on an inferior standard. Because, to lower the distinction would be unjust towards those who by extended study and diligence have already obtained these titles from the University of London or other universities which maintain a high standard. Because it would be injurious to the interests of the public and to the advancement of medical science to lessen the inducements to men of ability to attain the superior knowledge required for the highest distinctions. That to establish a second university in London with the purpose of granting the same or similar titles for a lower standard of acquirements, would be a competition downwards, and be utterly unworthy of such bodies as the Royal Colleges of Physicians and Surgeons. That the injurious consequences would be intensified if a medical degree were given on the existing standard of the professional examination of the Conjoint Board. That this would in its first effect be unfair towards those who have already passed the same or like examinations without receiving such degree; and in its ultimate result, by making medical degrees nearly universal in the profession and no longer a distinction, would be utterly destructive to the purpose they have served as inducements to superior attainments in medical science."

The resolution was seconded by Dr. Sturges. Sir Henry Pitman, Professor Latham, and others opposed the resolution.

The discussion occupied nearly two hours, and ultimately the resolution was lost, six voting in its favour and fourteen against. Eight members of the Club who were present did not vote.

Professor Latham then proposed the following resolution, of which he had given notice:—"That it is expedient that a committee be appointed whose duty it shall be to consider from time to time the regulations relating to degrees in medicine in the University, to receive and consider suggestions for the improvement of medical education there, and to take such action as they deem necessary."

The resolution was seconded by Dr. Abercrombie, and after a brief discussion it was resolved to adjourn its consideration to the next general meeting of the Club.

The meeting ended with the usual vote of thanks to the Chairman.

MEDICAL APPOINTMENTS IN THE COLONIES.

A SHORT account of the medical appointments which are from time to time filled up by the Colonial Office has been recently forwarded to the medical schools. The medical officers are chiefly required for the West Indies and the West African colonies, and very occasionally for the Eastern colonies (Ceylon, Straits Settlements, and Hong-Kong), Cyprus, Gibraltar, St. Helena, and the Falkland Islands. On the opposite page we have tabulated the chief points in respect of the separate colonies, for easy reference.

In addition to the ordinary medical appointments in these colonies, vacancies also occasionally, though very rarely, occur for which specialists are required—as, e.g., to take charge of a lunatic asylum; and the particulars connected with the post of chief medical officer in some of the larger colonies have not been given, as the headship of the medical department in such colonies, requiring administrative as well as professional qualifications, is not reserved to the ordinary medical staff, but is often filled up directly from the outside.

All applicants for medical employment in the colonies must be between the ages of twenty-three and thirty, and must be doubly qualified; preference will be given to those who have held hospital appointments as house-physicians and house-surgeons; certificates of moral character and of sobriety will be required, and every officer before being appointed will be medically examined.

Applications for medical employment in the tropical colonies from persons in the United Kingdom must be addressed to the Private Secretary, Colonial Office, Downing-street, S.W., during the month of April in each year, and notices to that effect will be posted up early in the year in the leading hospitals and medical schools of Great Britain and Ireland. Out of the total number so applying a list of thirty selected candidates will be made, who will be eligible to fill any vacancies which may occur during the year, and no application at any other time for ordinary medical appointments will be entertained.

From twelve to sixteen vacancies usually occur annually.

Digitized by Google

TABLE SHOWING THE MEDICAL APPOINTMENTS IN THE COLONIES FILLED UP FROM THE COLONIAL OFFICE AS VACANCIES OCCUR.

Place.	Number of appointments.	Salary per annum.	Pension.	Leave.	Passage-money.	Private practice.	Remarks.
Jamaica	49	£159 to £250	No. 4 per cent. of salary deducted for a widows' and orphans' fund	On half-pay in case of sickness, or after 6 years' service	Allowed on first appointment	Yes, with a district appointment, but not to new-comers	
Trinidad	26	£300, with furnished quarters	Yes	Yes	Yes	Yes, with district appointments	Must serve 1 year's probation as supernum.
British Guiana	45	£300, with quarters, gradually increasing to £900	Yes. Also 4 per cent. deducted as above	Yes	Yes; but not more than £30	Yes, with a district appointment, and then £100 to £150 yearly also allowed for travelling expenses	2 years' probation
Windward Islands	23	£200 to £400	May be granted	May be granted	May be allowed on first appointment £30	Yes, with district appointments	
Leeward Islands	22	£150 to £400 (average £250)	None guaranteed	Yes		Yes	
British Honduras	3	£100, £150, and £150	Yes	Yes	Yes	Yes	Special fees as public vaccinators
Fiji	8	£300 to £350, and £50 extra for house allowance	Not yet established	Yes	Yes	Yes	
Western Australia	Occasionally sent out at request of Governor	From £100	None guaranteed	—	Usually £100	Yes	
West African Settlements:							
Sierra Leone	4	£250, £250, £300, and £500, with £45 12s. 6d. for travelling allowance for juniors, £91 5s. for senior	As in the case of other Government servants	As in the case of other Government servants	—	Yes	
Gambia	2	£300, £400	,, ,,	,, ,,	—	Yes	
Gold Coast	10 assistant-surgeons	£400, rising to £500	,, ,,	,, ,,	—	Yes	
	1 colonial surgeon	£800, rising to £1000	,, ,,	,, ,,	—	Yes, but only consultation practice	
Lagos	2 assistant-surgeons	As at Gold Coast	,, ,,	,, ,,	—	Yes	Free quarters, or allowances in lieu thereof
	1 colonial surgeon	£400, rising to £500	,, ,,	,, ,,	—	—	
Ceylon	4 deputy assistant-surgeons	1500 Rs.	As other Government servants in Ceylon	,, ,,	As other Government servants	Yes	Deputy assistants are mostly recruited from gentlemen born in the island possessing a British diploma
	24 assistant-surgeons	3000 Rs. to 5000 Rs.				Yes	
	4 colonial surgeons*	6000 Rs. to 8000 Rs.				Consultation practice only	
Straits Settlement	7	Not uniform; average $2400	,, ,,	,, ,,	,, ,,	Yes	
Hong Kong	A colonial surgeon	$2880, with $288 for conveyance, and $864 for Lock Hospital	,, ,,	,, ,,	,, ,,	Yes	
	A superintendent of the civil hospital	$3000, and quarters	,, ,,	,, ,,	,, ,,	No	
	A resident surgeon at the Lock Hospital	$1800, and quarters	,, ,,	,, ,,	,, ,,	No	
	A health officer and inspector of emigrants	$2000	,, ,,	,, ,,	,, ,,	Yes	
Gibraltar	Port surgeon	£150	—	—	—	Yes	
	3 district officers†	£70, £70, and £60	—	—	—	Yes	
	Visiting surgeon to prison and lunatic asylum	£60	—	—	—	Yes	
	Officer of health	£100	—	—	—	Yes	
Cyprus	1 chief medical officer	£500	—	—	—	Yes	
	2 district officers	£250	—	—	—	Yes	
St. Helena	1	£200, and £30 horse allowance	—	—	—	Yes	
Falkland Islands	2	£200, £300	Yes	Yes	Yes	Yes	

* Three superintending officers, 7 district medical officers, and 8 assistants, with the pay and privileges above noted, are appointed to take care of the labourers on coffee and other estates.
† About £25 each as public vaccinators.

THE ASSOCIATION OF GENERAL PRACTITIONERS.

A MEETING of the Council of this Association was held at Exeter Hall on Wednesday, Jan. 19th. The following members of Council were present:—C. G. Wheelhouse, Esq., F.R.C.S. (Leeds), in the chair; Sir W. Foster (Birmingham) Mr. Ernest Hart, Dr. Alfred Carpenter (Croydon), Dr. Danford Thomas, Dr. Crowe (Worcester), Dr. Mickle (Bow), Mr. Steele, Mr. Wickham Barnes, Dr. Alderson, Dr. Gubb, Mr. Walter Pocock, Dr. J. B. Brierley (Manchester), Mr. Walter Marsh Dr. Maurice Davies, Mr. Major Greenwood, Dr. R. Paramore Mr. A. D. Roe, and Dr. W. Piercy Fox, and the hon. secs., Messrs. Bott and Verdon.

Letters of apology and assent were read from absent members of Council, including Mr. Jalland (York), Dr. Holman (Reigate), Mr. Hallowes, and others. Fifty new members were elected, and the following were added to the Council:—Mr. E. Galton, Dr. C. Royston, Dr. R. Lord, Mr. F. B. Hallowes, Dr. H. C. Pope, Mr. J. W. Workman, Dr. H. J. Capon, Dr. M. Coates, Mr. T. E. Walford, Mr. J. Manley, Mr. W. Eddowes, Mr. Hugh Aker, Mr. W. Winterbotham, Mr. De Vere Hunt, Mr. T. S. Ellis, Mr. Priestley Smith, Mr. J. S. Bartrum, Mr. J. S. Turner, and Mr. F. Wallace.

Mr. WHEELHOUSE said: "I must thank you very cordially for placing me in this chair, and assure you that, so far as it is in my power to aid the objects of this Association as they have been put before me, they shall have my heartiest and most cordial support in every way. We cannot conceal from ourselves the fact that we are living in critical times, when everything, so far as the profession is concerned, appears to be on the point of turning, and it is just at that point of turning when it behoves us as general practitioners to see that our rights are not swept away as the tide flows round. The question was raised during the late election for the General Medical Council as to whether I was a consulting surgeon, a general practitioner, or what? I have been a general practitioner all my life. I am a general practitioner still in a somewhat restricted sense, for when I accepted a seat in the Council of the Royal College of Surgeons, it became necessary that I should forego the practice of midwifery and the dispensing of medicines. I still have a large family practice, and although those amongst whom I live choose every now and then to ask my opinion in consultation, I do not think that that should redound to my discredit, at all events. Now, there seems to be a very general feeling throughout the profession that the rights of the general practitioner were likely to go by unheard unless the general practitioners themselves looked after those rights in all the changes which seemed about to come upon the profession. For a very long period—certainly for twenty-five years—I have been working with the Medical Reform Committee of the British Medical Association in the hope that by patient plodding and by patient working we should after a time, at all events, secure for the profession certain definite rights, and these rights appear now to be within reach of our hand. It seems to me that with this very general desire upon general practitioners to look after our own rights, some such Association as this has become a necessity. In the first place, it has seemed to me perfectly monstrous that so far as London schools and London-educated men are concerned they have no means of taking an ordinary M.D. degree; and whilst you are about it I think you are perfectly right in putting that as one of the points upon the programme for which you contend, and I hope the upshot will be in the end we shall obtain a right to that qualification, or some means by which those educated in London may obtain it without having to go beyond the limits of London itself. Amongst other things we have been striving for, and one to which I have looked all my life with very great hope, is that we should live—at least, some of us—to see one portal, and one portal only, by which those who enter our profession may be admitted to it. With twenty competing bodies there must be a competition which must be unfavourable to the general mass of the profession in the way in which their examinations are conducted. If we cannot have one portal for the whole profession, I should like, as the nearest approach to it, one portal for England, one for Ireland, and one for Scotland, and I would have those under the guidance of the one examining body which will be instituted, I hope, in the near future; and each of these kingdoms should make it an absolute necessity that every man who enters the profession should pass through that portal, and should be made to show that he is efficient in the arts of medicine and surgery. I hope that there will be some means by which the general practitioner, if he says 'I don't care to stand upon this same dead level in which I entered,' may be able to pass into a higher status. If he be a surgeon, he may desire to obtain his Mastership or Fellowship in Surgery. In the same way I would have a medical degree within reach, so that everyone who takes medicine in hand can be able to obtain a London M.D. degree which shall place him upon an equality with the M.D. obtained either in Dublin, Edinburgh, or any other large European centre. In order to do that, I think we should need a very considerable modification in the way in which examinations are conducted. I am one of those who look upon the examinations of the present day as unsatisfactory in more ways than one. I consider they are broken up into many minor matters. A man is called upon to pass too many examinations, and to pass them in such a way that he thinks when he has passed any one subject he may forget it as quickly as he likes. I would therefore diminish the number in which he is called upon to pass examinations. I believe that examinations are conducted too hastily, too cursorily; that they are conducted in a way which is not strictly fair to the student or to examiner, and I think there are changes in the method of examination which, now that new examination halls are to be erected, may be forced upon the attention of those who constitute the examining bodies. I have been very much grieved at what has taken place with respect to both the College of Surgeons and the College of Physicians in the action they have taken with respect to the Apothecaries' Society. My feeling is that if we could see those three bodies so united as to form the examining body of the kingdom, the one-portal system would be within our reach. But when I saw, with all the desire on the part of the Apothecaries' Society to join heartily in any scheme which may be propounded, that that offer was rejected, I felt that pressure ought to be brought to bear upon the Councils of the College of Surgeons and the College of Physicians, and, if need be, on the Privy Council itself, to pray if possible that this arrangement may not be completed if it is not heartily accepted. I hope that this Association will be able to put such pressure upon the examining bodies, upon the governing bodies, and upon all the bodies concerned with medical education, that we shall eventually succeed in obtaining that for which every general practitioner has been fighting for a long time."

Dr. ALDERSON moved the following resolution:—"That this Association urgently appeals to the general practitioners of England to give their adhesion and support to the Association, by becoming members, in furtheranse of its important objects, which are briefly as follows: That this Association regards with satisfaction the proposal for securing to the general practitioners of England in the future means of obtaining the M.D. degree in London by reasonable and adequate examination tests." Dr. Alderson thought the success of the Association was assured. They were most fortunate in having as their president the most representative medical man in the kingdom. He (Dr. Alderson) felt a particular interest in proposing this resolution, inasmuch as he had not only met with some little difficulty in getting his own degree; but he had been compelled to send a son of his away to Durham. Why, he asked, should London have only given her diploma to thirty-six men during the past year? Could it be that there were only thirty-six students in the whole of London worthy of that degree? The student's career should be progressive.

Mr. MAJOR GREENWOOD said he had great pleasure in seconding the resolution, and expressed the hope that some alteration would take place in London with regard to the granting of degrees. The London University could not in any sense be said to fulfil the requirements of a London University. There were many students who desired to complete their curriculum after having engaged in practice who found it impossible now, compelled as they were to return to the hospital, and go through the whole curriculum again. He hoped when a new University was instituted that it would help those who failed to carry out the full curriculum at the present London University.

The resolution was carried unanimously.

Mr. WICKHAM BARNES moved the following:—"That this Association protests against the exclusion of the

Digitized by Google

Apothecaries' Society from the Conjoint Examining Board of England as tending to create a division of medical interests to the public and to the profession." He stated that he had inserted two notices in the Medical Press asking the members of the Poor-law Medical Officers' Association to express their opinion upon the question. As the result he had received 200 replies, only one being opposed to the admission of the Apothecaries' Society to the conjoint examination.

Mr. STEELE said he had much pleasure in seconding the above resolution. The action of the College of Surgeons in ignoring the resolution passed at one of its meetings was conduct which could not be approved. The position of the Chairman on the General Medical Council was a protest by the general practitioners throughout England that henceforth as general practitioners they intended to have some voice in matters affecting their interests. The fact that the Apothecaries' Hall had been omitted from the conjoint scheme showed the necessity for vigorous action on their part.

This resolution was passed unanimously.

Dr. DANFORD THOMAS, in moving the following resolution—viz., "That this Association claims for the general practitioners of England, Members of the College of Surgeons, and Members and Licentiates of the College of Physicians a representative voice in the governing bodies of the respective Colleges, of which they are the main support,"—said this was a matter in which he was specially interested, and from his connexion with a kindred Society—viz., the Association of Members of the College of Surgeons, which had been working for some two or three years now in endeavouring to obtain the right of the representation of members on the Council of the College. The success which had recently attended their efforts to secure representation on the General Medical Council, and the honour they had in seeing two of those gentlemen who had been elected present, should encourage them to commence work with the view of obtaining the reforms set out in the resolution. What Parliament had realised they should be successful in carrying out in a minor degree. They had now their representatives on the General Medical Council, and they intended to fight—he hoped successfully—for representation on the Council of their College. They had, he thought, met with considerable success with regard to the work they had done in the Association, to which he had referred, and he believed the Council would now be willing in some way to meet them. The steps they had taken had, he thought, been to some extent more favourably received than hitherto, and if necessary they were determined to take the course to be pursued by this Association, and petition the Privy Council. They had received a similar reply from the Privy Council, stating that no new Charter would be granted to the College until they had had an opportunity of being heard. This Association went further, and said that the licentiates of the College of Physicians should also have a representative voice in the governing body. That, he thought, was only fair and just.

Mr. A. D. ROE seconded the resolution, which was carried *nem. con.*

Sir WALTER B. FOSTER said as regards the principle of the resolution it had had his support from the beginning. He believed he was the first member of the profession who publicly announced that that principle was the only one on which the College of Surgeons could hope to flourish. He published a pamphlet, entitled "The Political Powerlessness of the Medical Profession," and in that he pointed out that the Council of the College would never speak with the full force of authority with which it ought to speak until it rested on the full 16,000 members of which it consists. He believed that was the only principle on which the two Colleges ought to be constituted. Everyone who held a diploma from the Colleges had a right to some voice in the body with which he was connected. It was, he contended, wrong for one portion of that body to exclude another. He (Sir W. Foster) believed that Members and Licentiates were equally interested in the College to which they belonged as Fellows, and he wanted them all to be interested. He was heartily with them.

Dr. BRIERLEY (Manchester) said he had been asked to propose what was, perhaps, the most important resolution on the paper. He did so with very great satisfaction. It was: "That this Association asks for a Royal Commission of inquiry into the constitution of the said Colleges as a preliminary to the granting of any Charter for the extension of the powers and privileges of these two corporations separately or in conjunction, unless such Charter be framed so as to give to the general practitioners, who compose upwards of 95 per cent. of the profession, a just voice in the governing councils of such corporation or university." Dr. Brierley said he quite agreed with them. They should never forget what infinite good the Apothecaries' Hall had done for medicine in the past, and he thought it was perhaps the most ungraceful act that could possibly have been done towards that corporation to exclude it from any new arrangement which might be made. He would have had nothing to do with the resolution if it had been to suggest a new power for the Apothecaries' Hall to confer a further degree. They had, as had been remarked, more than enough already. It was not new powers, but a reconstruction of the old that was required, and the merging into one scheme. With regard to the College of Physicians, he must say he held that qualification in very high esteem. He possessed that qualification. On the other hand, he had the profoundest respect for the licentiateship of the Apothecaries' Society.

Dr. GUBB, in seconding the resolution, said they had passed several resolutions, and after passing them the next thing for them to do was to give them effect. It was a very grave measure asking for a Royal Commission, but if they obtained it he thought it was extremely probable that it would fulfil their wishes.

The resolution was carried unanimously.

Dr. MICKLE suggested that the two questions, that of obtaining the London M.D. degree for medical students and the incorporation of the Colleges, should be kept distinct. The burning question was the one of degrees. Everyone who had watched the London schools during the last twenty years knew that the students laid under enormous disadvantages. This Association had already committed itself in a former resolution to support the obtaining of the M.D. degree, and it seemed to him very undesirable for the Association to do anything which would form an opposition to it. He thought the resolution might be so modified as to imply that no opposition would be given to the granting of the M.D. degree.

Mr. HART said he hoped no one would consent to this proposal, which practically meant selling their birthright for a mess of pottage. Now, when the Colleges were asking for new Charters, was the time to move for an inquiry into their constitution. The only ground on which they would go to the Privy Council would be to ask to be allowed to constitute a new University, and the only *status* they had was to go and say, "Yes, they were in favour of that, but the Colleges must remodel their constitution." If they were allowed to establish their new constitution on the present basis, they would be giving them so much added power.

Dr. MICKLE suggested that the two questions should be fought out on separate lines.

Mr. HART said the answer to that was that once the Colleges were allowed to obtain their new powers, they (the Association) had no further *locus standi* in the matter.

Dr. BRIERLEY said that he apprehended the very object of this resolution was to prevent any action being taken without its being carefully watched by a Royal Commission which would consider the whole question.

Dr. STEELE said everyone seemed to be very imperfectly informed as to what the Colleges were asking for. He understood that the Colleges of Surgeons and Physicians jointly asked for one thing. The College of Surgeons were asking for a new Charter which should give larger powers, and this his Association was opposing. The Colleges unitedly asked for power to give an M.D. degree. That they as an Association would support. The present Association had intimated its intention of supporting the Members, who were opposed to the College of Surgeons acquiring further powers which would exclude them from a voice in its affairs.

Mr. MAJOR GREENWOOD said they opposed any Charter for whatever purpose it might be asked which excluded Members of the College of Surgeons and Members or Licentiates of the College of Physicians from their Councils.

Dr. MICKLE withdrew his suggestion, and the resolution was carried unanimously.

Dr. POCOCK moved, and Dr. PARAMORE seconded, the next resolution, which was "That copies of the foregoing resolutions be forwarded to the Privy Council, with a request for an audience on the above matters, and that due steps be taken to bring them under the notice of medical corporations, the profession, and the public." This having been passed without opposition, the meeting closed by Dr. MICKLE proposing a vote of thanks to the chairman.

THE LANCET.

LONDON: SATURDAY, JANUARY 29, 1887.

IT is so generally the custom of medical men to leave the management of the sick room to the friends of a patient or to nurses, that it seems to be almost forgotten that this is, in a remarkable degree, a professional duty. "Treatment" does not consist wholly, or indeed chiefly, in the administration of drugs. The surroundings of the sick are not less important as agents of cure than the medicines given to them. Indeed, we will go so far as to say that in the best and most physiological methods of therapy drugs are only admissible as *aids* to the arrest of disease and the recovery of health, which Nature will accomplish if only the case be so conditioned as to remove obstacles out of her way, and facilitate the processes whereby she is working. The scientific therapeutist regards the placing of his patient in circumstances favourable to convalescence as the first and most urgent step he has to take, and it is therefore impossible for him to look upon the management of the sick room as of trivial or even subordinate importance. We have no thought of attempting to determine the particular conditions required for the recovery of the sick. Obviously these can only be indicated by the needs of each patient. We believe one and all *systems* of management must be open to the fatal objection that they do not deal directly with the lesser needs of the individual; and these lesser needs are in practice the most important. The point on which we are especially anxious to insist is that the practitioner ought to make the management of the sick room his most solicitous care. To relegate this part of his duty as a minister of health to a nurse, however skilled, or friends, however intelligent and solicitous for the welfare of the patient, is to surrender to others a power which may be either wasted or applied obstructively, with the best of intentions; and simply because, being dissociated from the exhibition of drugs, the management of the sick is no longer felt to be what it really is—namely, an integral and elementary part of treatment.

To manage the sick room wisely and efficiently, the practitioner must be so thoroughly versed in all the details of nursing as to be able himself to do, if necessity arises, all that he expects of others. The best illustration of what we precisely mean may be formed from the position of a captain commanding his ship in a storm. He not only possesses a general notion of what ought to be done, but he is practically acquainted with every rope and spar and sail in the vessel, and he could, if it were physically possible, perform the whole duty himself. He can supervise, because he has himself passed through every grade of seamanship, possesses the knowledge of *how* things are to be done, as well as what to do in the circumstances. Now we greatly fear that anything approaching to this practical familiarity with the details of the duty devolving upon a medical practitioner as a minister of health is rare, and daily becoming increasingly difficult to find among the most advanced and theoretically competent workers in our profession. Division of labour is no doubt a necessity of progress, but we cannot regard without uneasiness the erection of nursing into a specialty, separate from, and in large measure independent of, treatment. The profession is not, we think, aware of the magnitude of the sacrifice it is making in allowing this province of the art of healing to pass out of its grasp. The development of nursing as a craft has grown out of the neglect with which that function has been too long treated by those who ought to be its principal promoters and directors. The condition of matters exposed by CHARLES DICKENS in connexion with his personification of the old-fashioned nurse as "Sairey Gamp" did permanent service; and the nurses of to-day are confessedly as superior to their predecessors of forty years ago as the medical men of the present time are better provided with instruments of precision, and more skilled in the knowledge of both health and disease than were those of the last or a previous generation. Nevertheless, we cannot but feel that against this gain to the interests of good management in the sick room must be reckoned the very grave fact that the most erudite and expert of our cloth to-day are incomparably, and almost of necessity, less able to direct and control the conditions of the sick than the practitioners of a time when the average attainments of the scientific physician or surgeon were immeasurably less considerable than those of the least advanced and accomplished of our contemporary doctors. There is no marvel in this fact, because nowadays the details, and much more than the details, of the art of nursing are left to a class of persons who, whatever their devotion and intelligence may be, are certainly not qualified to take the position of medical practitioners. It is not with any disrespect to the class of skilled nurses that we protest against the growing evil of surrendering a large and most potent part of the art of healing to those who are not in a position to master it. No lasting success can possibly attend the separation of nursing from medicine. The doctor who does not himself direct the nursing of his patient in all its details cannot be held to have control of even half of the appliances of cure, and, for anything he can tell, the manner in which his patient is treated during the intervals between his visits may be such as, though admirable in themselves, must prove antagonistic to his own method and policy. We are not now thinking of the disastrous effects of bad or even careless nursing, but of the very best that can be procured. Nursing ought to play a leading *rôle* in treatment, and therefore it should be one of the first considerations of the practitioner. His should be the guiding hand in everything that concerns the sick, and to this end his authority and influence should be paramount. A great point is gained when it can be said of a practitioner that when he appears on the scene he takes not only general but specific control of the whole management of the case, and personally directs every detail. In no other way can perfect unity of aim and policy be secured. It may be argued that the busy practitioner has no time to spare for thus entering into matters; or that he descends from a high professional position when, for example, instead of contenting himself with simply ordering a poultice, he takes pains to ensure that it shall be properly made. How strangely erroneous such notions as these really are will appear when

Digitized by Google

we reflect that the most successful practitioners have been, and still are, those who possess, and do not scruple to apply, the most minute acquaintance with the art of nursing—a knowledge for the most part either acquired by painful experience in their own families or obtained by years of observation and practice in the wards of hospitals where homely rather than ornate systems of nursing were in operation. It must be frankly confessed that we do not see how the students of to-day are to learn the art of nursing in such a way as to render them really able and useful practitioners in private families, seeing that the management of the sick and of the sick chamber is an art and mystery studied and practised by a separate class of non-medical persons, who cannot share the practitioner's responsibility.

IN view of an early meeting of the General Medical Council, it is worth while to consider the composition of that body as affected by recent legislation. The Medical Council of 1887 will be in its representative character and in its *personnel* different from any Medical Council that has ever sat. For one thing, and a very important thing, it will be larger. It will consist of no less than thirty-two persons, instead of twenty-four. The President, Sir HENRY ACLAND, will continue to be a member of the Council and its President in virtue of the provision in Section 9 of the Medical Act of 1886, that "nothing in this section shall affect the duration of the term of office of the person who at the time of passing of this Act is President of the General Medical Council." At the expiration of Sir HENRY'S term of office in 1889, the Council will be required by the Act to choose its President from one of its own members, instead of being allowed as heretofore to go outside. Similarly the number of Crown representatives is unaffected—that is, continues at four for England till the first expiration of the term of office of one of them, when the number will be reduced to three for England. It is satisfactory that Sir HENRY ACLAND will initiate the change from the old Council to the new. He has been a member of the Council ever since its formation. Only he and Dr. AQUILLA SMITH have this distinction. Whether Sir HENRY ACLAND has ardently longed for the changes which have taken place in the Council or not is a matter of doubt, but he is quick to see the good in actual and accomplished facts, and generous enough to regard without fear a direct representation of the registered practitioners, and even an enlarged representation of the individual bodies.

The new Council will contain several persons who have never sat in it before—viz., Dr. BRUCE of Dingwall, Mr. R. B. CARTER of London, Sir WALTER FOSTER of Birmingham, Dr. GLOVER of London, Dr. KIDD of Dublin, Dr. WILLIAM MOORE of Dublin, Dr. LEISHMAN of Glasgow, and Mr. WHEELHOUSE of Leeds. Sir WILLIAM TURNER will enter the Council, not indeed for the first time, but for the first time in his new capacity as representative of the University of Edinburgh alone. He has repeatedly sat, and that with much effect, as the representative of the two Universities of Edinburgh and Aberdeen. The latter University will be henceforth represented by Dr. STRUTHERS, and Sir W. TURNER will have his hands free to vindicate the ways and interests of the great University of Scotland. Few bodies have gained more than the Scottish Universities by the recent Act. It was admitted on all hands that the Act of 1858 was indefensible when it gave only half a representative to such a body as the University of Edinburgh, while giving a whole one to the Apothecaries' Society of Dublin and to the Faculty of Glasgow. Now the Scottish Universities will be represented by four members in the Council; the representatives of Scottish Corporations will be three in number; the Crown in Scotland will have one representative as heretofore; and there will be the new direct representative—from all accounts a good typical specimen of a medical Scot, contending creditably with disease and climate in the extreme north, and yet so interested in problems of medical education and registration as to be willing to take a journey of four or five hundred miles for their promotion. Fully a third of the new Council, about to sit, enter it for the first time, or in a new capacity. Of the thirty of which the Council will ultimately consist, nine will represent Scotland, as against seven representatives for Ireland and fourteen for England. It will be curious to see how the different elements of the new Council will comport themselves—how they will combine and how contend; whether Corporations will combine against Universities, or "nation rise against nation," or the Direct Representatives preserve their happy independence of "Bodies." They will constitute only one-sixth of the whole Council—too small a proportion to greatly affect the issues, though large enough, let us hope, to be of some use. Numerically the Universities will be the most represented interest in the new Medical Council, having eleven representatives, against nine of the Corporations, five of the Crown, and five of the registered practitioners. The extension of the principle of individual representation of bodies in the Council is a very serious feature and fault of the late Act. But our simple object at present is to indicate the elements in the composition of the Council.

THE two past numbers of the *Journal of Anatomy and Physiology* contain an article on "Intra-peritoneal Blood Transfusion and the fate of Absorbed Blood," by Dr. WILLIAM HUNTER of Edinburgh, which has an important bearing at the present time, and demands the most serious consideration from those who advocate intra-peritoneal operations for the removal of effused blood. The observations form part of an Edinburgh graduation thesis, and, although not yet published in their entirety, are of much importance, and will necessitate a reconsideration of some of the principles which are often urged for immediate operative treatment in cases of intra-peritoneal hæmorrhage. The experiments and observations are very striking, obviously most trustworthy, and deal most fully with the absorption of blood introduced experimentally into the peritoneal sac. They were undertaken with the view of observing what effect extravasation *per se* had on the life-duration of the absorbed corpuscles, and of determining the seats and methods of blood destruction within the body; but incidentally they happen to be of especial interest in regard to the absorption of the blood from the peritoneal cavity and the dangers of its presence therein. From 30 to 90 per cent. of the quantity of blood calculated to be present in the body was transfused within the peritoneum of rabbits, and occasionally of dogs. In certain cases defibrinated blood was used; in other cases entire blood was transfused directly from the carotid of the one

Digitized by Google

animal into the peritoneal cavity of the other, and this latter class of investigation forms the special set of experiments to which we would particularly draw attention.

In the cases in which defibrinated blood was employed no special immediate effects were noticed, and the question of the fate of the corpuscles under such circumstances, though very interesting and valuable from a physiological standpoint, are comparatively beside the more important issue—viz., what happens locally and generally to the animal experimented on when such a large quantity of normal blood is introduced into this great serous sac. In only two instances out of twenty-five experiments did death follow, and this result was directly traceable to a septic condition of the syringe used for injection. In other words, blood within the peritoneum, unaccompanied with sepsis, led to no danger whatever. In some instances the transfusion was repeated several times in the same animal—notably in one in which blood to the amount of 200 per cent. was introduced four times in the course of three months, and in another in which transfusion was performed three times within two months. The most striking feature in the experiments was the slight amount of harm due to the transfusion. In cases in which defibrinated blood was used the animals were almost entirely unaffected; and even when blood not deprived of fibrin was employed, the operation was accompanied by only slight loss of appetite and fall of body weight for the first three or four days, doubtless due, as the author suggests, to some localised peritonitis. The rapidity with which coagulation takes place—for in the interim the blood practically behaves as a fluid,—and its distribution previously to coagulation, are the two main factors which determine the amount of absorption. The conditions on which rapid or slow coagulation depends cannot be defined beforehand in an individual case, but the distribution of the extravasated blood gives rise to this most important consideration: "If the blood remains *en masse* at or near the seat of extravasation, coagulation, when it occurs, will be likely to involve the greater part of it, with the result that a clot of some size will be formed which will serve to entangle the great majority of the extravasated corpuscles. Under such circumstances the amount of absorption which takes place may be extremely slight." If, on the other hand, the blood, on being effused, escapes amidst the neighbouring organs before coagulation takes place, not only will coagulation be longer delayed, but even when it does occur the clots which form will be much smaller in size, although perhaps more numerous, and larger numbers of the corpuscles remain free to be absorbed." The post-mortem examinations and experiments fully bear out the writer's conclusions: under the former conditions a large caseous mass, thirty grammes in weight, was found in the abdomen; under the latter only a small caseous nodule not larger than a marble remained.

It is very manifest that, however much effusions of blood under pathological conditions may differ in their behaviour from those which take place into the healthy abdomen, these experiments and observations suggest an expectant treatment, rather than immediate or hurried operative procedures.

THE elevation of Professor BILLROTH, the eminent surgeon, to the peerage of Austria revives the vexed question of medical peerages in this country. Why should England alone of all nationalities refuse to admit members of the profession of medicine to the higher social ranks? It is the more inexplicable that this refusal should be maintained because there would seem to be no scruple as to the elevation of successful tradesmen of all classes. Surely the professors of an art which, being really an applied science, directly concerns the physical and mental capacities of the people for prosperity and happiness, are not less worthy of admission to the most exclusive order than men who have amassed wealth by the manufacture and sale of beer, or by trading in any one or more of the necessaries wherewith the body is nourished or clothed or warmed, or its comfort promoted! Taking the lowest view of the question, and conceding that, possibly, medicine and surgery are among the most degraded of arts, it can scarcely be contended that those who study and practise them are of viler clay than the successful purveyors of coal, iron, wood, beer, and other vulgar commodities, who have achieved "greatness." It is difficult to suppose that any sensible man of culture who knows the hollowness of conventional dignities as the practitioner of medicine knows it can hanker greatly after a peerage; but this does not in the least degree affect the fact that those who persistently refuse peerages to medical men are neither very politic nor very consistent. We are glad that Professor BILLROTH has achieved the distinction he so well deserves, and we commend the subject of peerages for medical men to the renewed consideration of those who advise the Sovereign in this year of jubilee 1887. It would be a timely moment for the ending of a senseless policy and the wiping away of a needless reproach—namely, that members of the profession of medicine are the only persons *systematically* excluded from the peerage of the United Kingdom.

Annotations.

"Ne quid nimis."

A NEW CHOLERA FUNGUS.

A REPORT of the Commission upon Cholera which was despatched to Spain last year by the conjoined action of the Royal Society, the University of Cambridge, and the Association for the Promotion of Scientific Research, has appeared in the proceedings of the first-named body. The commission consisted of Drs. Roy, Graham Brown, and Sherrington, and the report, although "preliminary," contains matter of much importance and interest. Twenty-five typical cases of cholera were examined, either immediately or at a short interval after death, with the result that Koch's comma bacillus was not discovered in the intestinal canal in all the cases. In some this microbe was present in great abundance; in others it was far less conspicuous; whilst in many undoubted cases, where death occurred before the reaction stage set in, it could not be detected at all. These observations were confirmed by the results of plate cultivations in gelatine and agar-agar. Moreover, it was found that when present the comma bacilli were collected either on the surface of the mucosa or so close to it as to suggest a penetration of the epithelium after death, but in the majority the organism could not be found in the mucous membrane or in any of the tissues or organs. These results, which are directly opposed to Koch's, are considered to be conclusive against the bacillus having a pathogenic relation to the disease; but it is suggested to

Digitized by Google

be the cause of the premonitory diarrhœa, which is held not to be a mild attack of Asiatic cholera, but only a predisposing condition. Having thus satisfied themselves that the comma bacillus is not the cause of cholera, these investigators similarly dismiss the claims of Emmerich's straight bacillus to that distinction, and also state that they were unable to recognise Klein's straight bacillus in any of their preparations. An interesting fact is their examination of specimens of Ferrán's inoculation fluids and cultivations. These were found to contain several forms of bacilli and micrococci, but no comma bacilli and none of the peronospora bodies which Ferrán describes as developed from the commas. The inference is that not only can the inoculations practised by Ferrán have no protective power, but they are dangerous from the risk of inducing septicæmia. The pathological characters of the choleraic intestine as described by Strauss and others are confirmed, and some valuable remarks are made upon the nature of the intestinal flux. This hyper-secretion has none of the characters of catarrh, nor does the bowel present any lesions suggestive of its being due to the presence of an irritant. On the other hand, Moreau's observation is confirmed, which demonstrates the close similarity of this excessive secretion to that induced by section of the intestinal nerves. It is suggested, therefore, that the choleraic flux may be owing to some causes acting on the glands or mesenteric nerves or ganglia. The search for a pathogenic parasite was continued by the commission after their return from Spain, and many months were occupied in the task. At length the discovery was made of a fungus, present in the intestinal mucosa of every case, at varying depths from the surface, and also in the kidney and liver. This fungus, consisting of granular masses and a delicate mycelium, which could not be stained without difficulty, was pronounced by Messrs. Vine and Gardiner to belong to the Chytridiaceæ, a class which includes many rapidly-growing and virulent parasites of vegetables. The difficulties of its detection may have led to its being overlooked by former observers; whilst the objection of possible after-contamination is met and refuted. At the same time, it is stated that further investigation is needed, especially in the cultivation of the fungus, before the discovery can be held to be conclusive.

THE ISOLATION OF FEVER NEAR BRADFORD.

THE Local Board of Health for North Bierley have very wisely come to the conclusion that it is their duty to provide their district with a hospital for the isolation of cases of infectious fever; the need for such a hospital being the more pressing because the Bradford Fever Hospital, hitherto a public institution open to the districts around Bradford, is to be for the future handed over to the Bradford Corporation, and to be retained for the purposes of the borough only. Both decisions are wise ones. The Bradford Fever Hospital is certainly not, in point of accommodation, in excess of the requirements of the borough, and North Bierley stands in need of a place near at hand to which first attacks can be promptly despatched for isolation as well as for treatment. From the discussion which took place, it is evident that the subject had been carefully thought out in advance. Mr. Whitteron, the medical officer of health, very properly explained that the needed building could not be regarded as sufficing to deal with an epidemic; its object was to provide such a number of beds as would prevent an epidemic. At the same time it is important, in the case of a new hospital, that the authority should take sufficient land to enable them to put up temporary additions if needed. Then came the question of single action, or joint action with other authorities near by. This must almost necessarily be a matter to be decided by local feeling. If districts so adjoin that one hospital will serve for several localities, it is obviously cheaper to combine, instead of going to the cost of providing several sites, several administrative buildings, and several groups of pavilions; the cost of maintenance is also borne by a larger number of contributors. But the only satisfactory method of uniting is by means of a Joint Board formed under a Provisional Order, and this means delay and an additional local organisation. Under these circumstances North Bierley has decided to act alone. With regard to the cost, it is hoped that it may be publicly subscribed, and that the building may thus come to form a memorial of Her Majesty's Jubilee. A more appropriate method of commemorating a reign, which has been more marked than any that has ever preceded it by the success of efforts to control the spread and mortality from infectious diseases, could not well be conceived. But there is just one aspect of this method of raising the needed funds, as opposed to the system of building the hospital out of a loan raised on the security of the rates, that is worth notice. If the former practice were adopted, the Bierley Local Board were informed they would be free from interference on the part of the Local Government Board. Now we have no reason for suggesting that the authority should in any way that they do not desire place themselves under the instructions of the central body; but at the same time we know of similar hospitals that have been constructed without the guidance of official advisers, that have come far short of that which it had been hoped to attain; and we would hence remind the Local Board of North Bierley that, even in cases over which they neither have nor seek to have any control, the Local Government Board have been most willing to make suggestions, on plans submitted to them, and that these suggestions, coming from those who are constantly engaged in dealing with the question of infectious hospital construction, have been found most valuable. North Bierley had in 1881 a population of about 21,000, and a considerable proportion of these live in houses which cannot retain the infectious sick without risk of spread. Whether, therefore, all the necessary accommodation is provided at once or not, the authority should not, in the long run, contemplate less than some twenty beds. Perhaps the best plan would be to begin with one of the composite pavilions recently designed by the Local Government Board, and so contrived that under the same roof two diseases in both sexes can be received without practical risk of spread. Such a pavilion will always be needed, and under ordinary circumstances it will be the one which will be mostly in use.

MUSCULAR ATROPHY CAUSED BY "HYDROMYELITIS."

DR. C. WALLIS of Stockholm reports an interesting case occurring under his care in the Sabbatsberg Hospital, where a peculiar affection of the spinal cord, which he calls hydromyelitis, had produced progressive atrophy of the muscles. The patient, a peasant aged thirty-eight, was admitted for empyema on the right side, of which he died in a week's time. He had noticed for some eighteen years a gradual impairment of the power of his right hand, and for seven or eight years of that of the left. The right hand was flexed (*in Krallenstellung*), with atrophy of the interosseous, flexor brevis, and opponens pollicis. A similar condition existed in the left hand, but to a less marked degree. The muscles of the right arm and shoulder were also slightly atrophied. At the necropsy, besides the empyema, atrophy of the muscles of the hands and forearms was found, and the same condition was also present in a marked degree in the deltoid and serratus magnus on the right side. Microscopical examination showed that in most of the localities where atrophy existed the muscular fibres had lost their transverse striated appearance, and that they were undergoing fatty degeneration. A centimetre below the medulla oblongata

Digitized by Google

the central canal of the spinal cord began to be dilated, attaining opposite the roots of the second and third cervical nerves a diameter of half a centimetre. The anterior cornua were greatly atrophied; the posterior cornua were of an abnormal shape, and displaced by the increased size of the canal, but were not atrophied. The distended condition of the canal continued without alteration along the whole of the cervical portion; below this it began to diminish, and at the same time the atrophy of the anterior cornua became less marked, but it was only in the lumbar portion that the cord presented its normal characters. The canal contained a transparent and very fluid liquid, and its wall consisted of a firm white membrane a millimetre in thickness.

CONSULTATIONS BY TELEGRAPH.

THE phrase "medical advice" is one which has assumed at different times very different meanings in accordance with the varying custom of practitioners. It usually does, as it should, imply that the recipient has been seen and examined by a medical man, so as to leave no reasonable doubt as to his illness, constitutional state, and appropriate mode of treatment. In order to arrive at this degree of security—the least that is required for any serious effort to overcome disease—it is commonly necessary and always advisable that a practitioner should be at the time in attendance on his patient. It does not necessarily follow that every prescription which is granted without regard to this rule is mischievous or ineffective. The arrow shot at a venture may hit the mark. The risk implied in such haphazard practice, however, may be very great. It is of two kinds. There is, firstly, the danger that remedies may do no good and no direct harm, yet cover and disguise the progress of disease; and, secondly, that actual injury may be caused to persons who are thus treated without respect to signs of illness other than reported symptoms. We do not deny that past experience of some patients will enable a medical man to sanction the continuance of a course of treatment, or even a change of minor importance, without a fresh attendance. Cases of this kind, however, are in reality such that the invalid understands his own management without the guidance of more skilled opinion. If any such plea can be urged in defence of the prolonged series of consultations for which the Atlantic cable is said to have been utilised, it has probably been strained to the utmost. Practice conducted on these principles is no better than a name. If it concern itself with graver matters it becomes unjustifiable, while its systematic exercise even in trifles is at best the harmless shadow of a dangerous custom, and does not accord with the true ideal of professional duty.

TYPHUS IN THE STOURBRIDGE UNION AND NEIGHBOURHOOD.

IT seems pretty clear from the local newspaper reports that typhus is prevalent in the Stourbridge Union, and that it has made its way into the workhouse. Of all places in which typhus constitutes a real danger, a workhouse is perhaps the worst; for it is the centre towards which destitution tends to congregate, and, as is well known, destitution, overcrowding, and that special form of filth which is attendant on those conditions, are precisely the circumstances which are favourable to the spread of typhus. It is true that a workhouse which is well ventilated, free from overcrowding, and provided with real means of isolation, may aid materially in checking typhus. But it is evident, from the interview which Dr. Mouat of the Local Government Board has had with the Stourbridge guardians, that these favourable conditions do not obtain in their workhouse; and Dr. Mouat found it necessary to warn them in grave terms as to what they might have in prospect. Already one nurse has sickened and died, and, as Dr. Mouat says, no true isolation is provided. And whilst this report reaches us, we find that Mr. Spear, another medical inspector of the Local Government Board, has interviewed the Quarry Bank Local Board, whose district lies in the same neighbourhood, and one mile from Dudley. From twenty-five to thirty cases of fever were found there, of which five have already terminated fatally. According to Mr. Spear, this disease was connected with filth, overcrowded houses, and destitution. This, too, looks suspiciously like typhus; and at this period of want of labour, and its attendant destitution and tendency to overcrowding, the significance of such events is all-important. The Local Government Board show that they hold this opinion by the despatch of two skilled medical officers into what is practically the same district.

ST. JOHN AMBULANCE ASSOCIATION.

WHEN the Colonial and Indian Exhibition was opened in May last, an ambulance station was, by permission, established in "Old London," under the direction of Mr. John Furley, with Mr. H. Percy Potter as honorary surgeon, for the use of the staff and *employés*, and of the visitors to the Exhibition, and was continued till the dismantling was completed at the end of November. During that time aid was afforded to 701 persons, of whom 41 were removed to their homes or to hospital on litters. Of the total number, 399 were cases of injuries and 302 of diseases, chiefly fainting, diarrhœa, epilepsy, and hysteria, and included two cases of drunkenness. An ambulance station was also established at Liverpool, in the grounds of the Exhibition there, of which Mr. F. T. Paul was the honorary surgeon, and Mr. Furley the honorary director. Between March 26th and Nov. 18th 248 persons received "first aid," and 11 were removed by horse ambulance or hand litter; 211 were cases of accident, wounds, &c., and 37 of disease, 18 of the latter being returned as fainting. In London one case and in Liverpool two cases of apoplexy are stated to have died subsequently to removal. These reports afford good evidence of the valuable work done by the Association under the superintendence of its able honorary Director of Stores.

SUICIDE WITH A DARNING-NEEDLE.

ON the 15th inst. Dr. Danford Thomas held an inquest at Clerkenwell on the body of Charles Nutter, aged seventy-seven, who was found dead in bed with a common darning-needle fixed in the epigastrium. Through the eye of the needle a cross-bar of tin had been threaded, and this had been fixed firmly in position by binding with worsted. The object of the deceased man (the jury returned a verdict of "Suicide whilst of unsound mind") was, no doubt, to make an instrument wherewith he could effectually encompass his end. Over the epigastrium and lower part of the chest were nine punctures: the one already mentioned as containing the needle, which had caused a superficial laceration of the liver; another had passed through the fourth right intercostal space and had penetrated the right ventricle and entered one of the posterior set of musculi papillares. Through the small puncture blood to the amount of nearly a pint had escaped into the pericardium, where it was found in part liquid and in part firmly coagulated. The remaining punctures had only extended into the abdomino-thoracic walls. There are several points of interest suggested for examination. In the first place, as regards the suicidal or homicidal origin of the wounds. The fact of a needle being used to inflict a mortal injury on an exposed part and being left *in situ* was of itself practically sufficient to negative the theory of murder; but there was further circumstantial evidence tending to show that deceased committed suicide. The heart

Digitized by Google

was greatly hypertrophied and dilated. This is important as furnishing presumptive evidence that the epigastric pulsation led the deceased to make the punctures where they were found, instead of, as is usual, more immediately over the cardiac region. The case shows that penetration of the cardiac cavities by means of a small instrument is not necessarily suddenly fatal, for it is clear that deceased must have lived for a considerable time—probably for an hour or more—after the fatal puncture was made, considering the size of the opening into the ventricle and the large quantity of blood found in the pericardium. No injury of the coronary vein or of either coronary artery could be detected.

THE MOXON MEMORIAL.

AT the meeting of the friends of the late Dr. Moxon, to be held on Tuesday next, Feb. 1st, at 5 P.M., at the Royal College of Physicians, it will have to be determined what form the proposed memorial should take. The first resolution will be moved by Sir James Paget, and seconded by Sir Andrew Clark. It would seem right that Dr. Moxon's name should be associated with Guy's Hospital, where he was physician and lecturer on medicine; but as many outside the Guy's *clientèle* have expressed a desire to assist in raising a monument to his exceptional talents, it is probable that the fund raised will be divided between Guy's Hospital and the Royal College of Physicians. It has been suggested that, after placing a tablet to his memory in Guy's Hospital, the remainder of the funds collected should be used to found a clinical medal, to be awarded, like the Baly Medal in Physiology, every alternate year, to the physician or surgeon most distinguished for clinical research.

"THE SPECTATOR" AND THE ERASMUS WILSON BEQUEST.

THE *Spectator* ridicules the idea of an Institution for Physiological and Pathological Research being needed, and founded in London, especially in the present year, lest it may one day be said that in the jubilee of the Queen's accession "one of those monstrous *bastilles* for the incarceration of creatures destined to the question of physiological inquisitors was founded in the capital of the most tender-hearted and truly humane of English sovereigns." It would be futile to enter into a discussion with our contemporary on such a subject, and we do not propose to do so. The foundation of a pathological institution will not in any sense "neutralise the Act of 1876"; it will *not* reconcile students "to horrors such as those which have hitherto been confined to continental capitals"; and it will *not* tend to obliterate in the minds of students "that scruple in subordinating the art of inflicting pain to the art of relieving it which has hitherto dignified the characters of our surgeons and physicians." There is little fear of such changes coming over the profession as are foreshadowed by the *Spectator*. "Sentiment and law" will continue, as heretofore, to actuate doctors in all their professional work. Our contemporary evidently misunderstands the uses of such an institution as the one proposed. If vivisection be carried on, it will be in strict accordance with the law, under the direct supervision of the Council of the College of Surgeons, and would thus be under more complete control than it is even at present. We imagine, however, that vivisection will form but a very subordinate part of the work to be done. There are physiological and pathological researches of the greatest value, which can only be studied in the dead subject; it is more than probable that the study of the intimate causes of disease and of the intimate effects of these causes may largely supersede other methods of research. The artificial cultivation of micro-organisms—"disease germs,"—their variation under varying conditions, in different cultivation-media, their analogies, antagonisms, and possible combinations, are the subjects which now attract professional attention, and it is chiefly for the study and elucidation of such questions that London demands a suitably equipped physiological and pathological research institution.

UNUSUAL SITE OF AN HYDATID CYST.

A CASE of hydatid of the scrotum came under the care of Mr. Philip E. Muskett in the Sydney Hospital during the course of last summer, and as this is an example of a very rare condition a brief note will be of interest. The patient, aged twenty-five, had been in Australia since he was three years old, and in a sheep district where the water was very bad for four years before the swelling appeared; this was first noticed eight years before he came under treatment. During that time it had been tapped twice, and on the second occasion also injected with iodine. When admitted to the hospital "there was an intra-scrotal tumour, about the size of a large emu egg, on the right side. It was smooth in outline and its general contour nearly oval. The tumour was tense and dull on percussion, but gave to the fingers on palpation the sensation of fluid within. There was no impulse on coughing, and it was irreducible. The position of the testicle at its posterior part was made out by the presence of testicular sensation. The cord could not be clearly defined at the upper portion of the swelling. Light was transmitted by the ordinary manner of procedure, and, finally, the history had been that of an eight years' growth: painless except from its mere weight." The cyst was tapped on the day following admission, and about an ounce of "serous-looking fluid" of pale yellowish tinge evacuated. Suppuration followed this tapping, and thirteen days later about six ounces of purulent fluid were drawn off. After this pus drained away from the puncture for eleven days, then a hydatid sac partly forced its way out and was partly extracted through this opening. The sac was greyish in colour, translucent, and elastic, and in its sunken condition would about fill an egg-cup. The swelling gradually subsided, the sinus closed, and the patient left cured.

EMIN PACHA.

ON the 21st inst. Mr. H. M. Stanley left England on his new expedition, the object of which is to effect the relief of Emin Pacha and to secure the withdrawal of the women, children, and non-combatants who are with him in a position of great danger in his province of Equatorial Africa. The fact that Emin Pacha is a member of the medical profession may not be known to all our readers. Dr. Hermann Schnitzler, better known as Emin Bey and subsequently as Emin Pacha, is an Austrian doctor, who was educated at Vienna, Paris, and Berlin, and is a man of great attainments, both linguistic and scientific. He has the reputation of being able to speak all the principal European languages, together with various African ones; and he has also an intimate acquaintance with geology, botany, meteorology, anthropology, geography, &c., on which subjects he has supplied valuable papers to many learned societies. Twelve years ago Gordon Pacha, who was then Governor of the Equatorial Provinces, appointed him Surgeon-General, and he held that post for four years, when he succeeded Gordon in the governorship. Since then he has been engaged in bringing a barbarous region into a state of civilisation, and, owing to the attacks of rebels from the north, has been for three years completely cut off from the outer world. During the first five years, at least, of his governorship he devoted any little leisure which his varied

Digitized by Google

duties left him to the healing of the sick. At sunrise every morning he was to be found in his hospital, and at night he used to write reports for scientific papers by the light of candles of his own manufacture. The preservation of such a man, and the rescue from the terrible dangers by which they are threatened of those he has for three years guarded with such magnificent and such heroic devotion, will be a feat which will add fresh glory to the already illustrious name of Stanley, and it is earnestly to be hoped that success, speedy and complete, may attend him in his errand of mercy.

LONDON POOR-LAW INFIRMARIES.

THE paper of Colonel Montefiore on Metropolitan Poor-law Infirmaries, and the importance of throwing them open to medical science, which was read at a meeting of the Hospitals' Association, Mr. Timothy Holmes in the chair, recalls attention to a subject of much importance, alike to the poor, the profession, and the public. The metropolitan infirmaries number fourteen, with 6803 certified beds; besides which there are eleven irregularly built institutions, with 5392 beds. In other words, they contain roughly double the number of sick beds of the great hospitals of London. The rate of expenditure was lightly touched on by Colonel Montefiore. He showed that different Boards pay very different prices for the same things. He pointed out that the medical officers had an enormous amount of work to do, and that for very modest salaries. In some cases two medical men had to attend 500 cases, besides having other duties to perform. He advised that these infirmaries should be brought into relation with the great hospitals, that the hospitals should supply their best men to fill the posts of the infirmaries, and that the medical superintendent of the infirmaries should be instructed to hold consultations with members of the consulting staff of the hospitals of the district in cases of unusual interest. We believe the Poor-law infirmaries are well officered, and their inmates now as a rule tolerably well cared for. But it does seem reasonable, and indeed has long seemed urgent, that provision for consultations should be made. It requires little imagination to conclude that 500 or 600 cases of sickness must involve much misery, and some difficult questions of duty and treatment, for which it is but reasonable to provide the opinion and help of more than one man. Indeed, it is scarcely fair to one man to make him responsible for all that 500 or 600 poor people may need, and we trust that, both for his sake and theirs, an arrangement for consultation will be conceded by the Local Government Board.

TO CURE LONDON OF ITS FOGS.

SIR H. W. TYLER has hit on the idea of doubling, or if need be, trebling, the duties on coal, with the proviso that these duties should be levied only on bituminous or smoke-producing coal, and that the smokeless sorts should be free of duty. From this legislative "protection" of the cause of colour and body in fogs he anticipates a very considerable diminution of the nuisance and injury inflicted by them. We heartily wish Sir H. W. Tyler success. It is an experiment worth trying. Meanwhile, it must be remembered that mists and fogs—properly so-called—we shall necessarily continue to have with us, at least until the prediction of another *savant* is fulfilled, and, some twenty millions of years hence, the sun grows cold, and, as the need for fuel increases, the mode as well as the means of providing heat utterly fails. We are fully alive to the fact that much would be gained by ridding the fogs of their carbonaceous impurities, but they would be none the less chill and raw, and nerve-depressing, for all that gain involves and implies.

CAMBRIDGE GRADUATES AND LONDON DEGREES.

WE are pleased to see that the medical graduates of Cambridge University were sufficiently liberal-minded to reject by a substantial majority Sir G. Paget's resolution:—"That to establish a second university in London for the purpose of granting medical degrees is either unnecessary or undesirable." Opposition from the existing universities may doubtless be expected, but it is gratifying to find that many of the members of the most important medical university in England are firm supporters of the scheme. If Sir G. Paget were more in touch with the London medical student, he would hear the most cogent reasons for the establishment of a second university in the metropolis, and he need not apprehend that it will lead to a competition downwards. Everyone connected with medical teaching agrees that the University of London insists on an absurdly high standard of acquirements, and that another university must be formed sooner or later in the metropolis.

THE GENERAL MEDICAL COUNCIL.

DR. WILLIAM MOORE, A.B. and M.D. Dub., was officially appointed on Tuesday last by the Queen as Crown Nominee for Ireland in the Medical Council. Dr. Moore is Physician in Ordinary to the Queen in Ireland, is physician to several hospitals in Dublin, and author of works on various medical subjects. Professor Rawdon Macnamara has been again chosen unanimously to represent the Royal College of Surgeons of Ireland in the Council. Mr. Macnamara has been in the Council for twelve years, and, while redoubtably defending his "Body" against all attacks, does so with unfailing good temper and "honest courtesy," of the good Irish type.

RED AND WHITE MUSCLES IN RODENTS.

M. RANVIER has again directed attention to the interesting difference of colour in the muscles of rodents. We refer to it because we believe that a careful study of the histology and experimental pathology of the corresponding nerves and spinal centres will bring fresh knowledge into a region where it is much wanted. There are great differences of organisation between guinea-pigs and rats on the one hand, and rabbits and hares on the other. In the hare all muscles are red, doubtless in relation to its greater agility; in guinea-pigs and rabbits some muscles are red and others white. The nuclei of the sarcolemma of red muscles are numerous and form longitudinal series. The semi-tendinosus and soleus of the rabbit are red, whilst the great adductor and gemelli are white. Although all the muscles of the hare appear red, yet the great adductor and gemelli have the same histology as the white muscles of the rabbit, whilst the semi-tendinosus and soleus have the constitution of the red.

TORSION OF AN INCISOR TOOTH.

MR. SMALE mentions in the *British Journal of Dental Science* the case of a boy aged eight who had the right upper central incisor twisted so that the mesial surface presented towards the lip. The tooth was grasped firmly by a pair of straight-bladed forceps and twisted into a good position, care being taken to press the tooth firmly into the socket during the operation. It was tied to the surrounding teeth with silk twist in order that it might not return to its old position. A week afterwards it was quite firm, the tooth could be tapped, and he could distinguish between hot and cold applications. There was no discolouration, and the gum was quite healthy. Torsion may be used freely before the patient arrives at the age of twelve years, and should be always done at one operation. It is only applicable to the incisors.

Digitized by Google

THE "VICTORIA READING CIRCLE."

IF, as Carlyle maintained, the diffusion of printed literature removed in great measure the necessity for universities, the establishment of public libraries must have still further reduced the need of those institutions. As if to impress this fact, we have had presented to us the syllabus of a newly-established "Victoria Reading Circle," the aim of which is to secure "at home some of the advantages of a college, so far as reading and study are concerned, without interference with other duties." This new society affords to adults whose early education has been defective, and to young people who have recently left school, a course of systematic reading in general literature. The whole course, like that of a university, extends over four years, each of which is divided into two periods or sessions. Certain readings are exacted as necessary, while others are optional. There are no examinations, but a guarantee is required to show that the works prescribed have been carefully read. Annual certificates, and finally a diploma, are granted to those candidates who have fulfilled their course and have satisfied the conditions laid down by the society. The admission fee, the cost of books, and the amount of reading to be done daily are each of them very moderate indeed, and the system as a whole, though yet untried, appears well calculated to foster a habit of self-culture, and at least in some degree to work out the Carlylean theory. The home of this new enterprise in education is at 56, Old Bailey, London.

REAL AND APPARENT DEATH.

IT was only last year that we commented in our columns upon the "signs of death," drawing attention to the more important criteria by which a skilled observer may avoid mistaking cases of so-called suspended animation from actual decease. Quite recently two instances have been recorded in which, if report be true, it would seem there is still room for maturing the judgment upon the question herein raised. At Saumur a young man afflicted with a contagious disease apparently died suddenly. His body was enshrouded and coffined, but as the undertaker's men were carrying "the remains" to their last resting-place they heard what they believed to be a knocking against the coffin-lid, and the sound was repeated in the grave. Instead of testing at once the evidence of their senses, they, in accordance with judicial custom, sent for the Mayor, in whose presence the lid was removed from the coffin. Whereupon, to the horror of the spectators, it was observed that the dead man had only just succumbed to asphyxia. The above narrative seems on the face of it too ghastly to be true, especially as the occupant of the coffin must have been shut up in a space containing oxygen in quantity totally inadequate to sustain an approximation to ordinary breathing. But in cataleptic and similar states the organic functions are reduced to the lowest ebb, and history records several instances in which, for a time at least, the determination of the living state was a matter of uncertainty. In our issue of the 15th inst., p. 129, the reader will find an account of "Post-mortem Irritability of Muscle," in which the phenomenon was manifested in a marked degree two hours after death from a chronic wasting disorder—a condition which favours early extinction of vital action in muscle. It may be argued, then, with some show of reasonableness, that it is quite possible for the heart to stand still, as it were, and yet retain the power of action, although experience tells us but little on the question as regards the human subject. Experiments on the lower animals, however, show that over-distension of the right cavities of the heart causes cessation of cardiac contraction, and that relief from the distension may be followed by resumption of the function of contractibility. It must not be forgotten that an analogous condition is witnessed at times in patients suffering from capillary bronchitis or other physical states underlying acute distension of the right heart; for, in these cases, venesection is not uncommonly instrumental in arresting the rapidly failing cardiac contractions. The second case of apparent death alluded to above happened in "the land of big things." An inhabitant of Mount Joy, Paramatta, was believed to be dead, and his supposed remains were about to be committed to the earth, when a mourning relative startled the bystanders by exclaiming, "I must see my father once more; something tells me he is not dead." The coffin was taken from the grave to the sexton's tool-house, and there opened, and was found to contain a living inmate, who justified the presentiment of hisson by "slowly recovering." As no mention is made in either case of the period that elapsed between the occurrence of apparent death and the body being placed in the coffin, or of the time during which the encasement lasted, special and minute criticism is uncalled for. Enough has been said on the subject to emphasise the exhortation: "Get knowledge, and with all thy getting get understanding."

THE SPHYGMOGRAPH IN ASYLUM PATIENTS.

DURING recent years the junior medical officers of our large asylums have recorded, perhaps more than in the past, observations on clinical pathology and morbid anatomy. We have repeatedly urged that these are profitable fields for investigation. Dr. Duncan Greenlees has an interesting paper in the current number of the *Journal of Mental Science* on observations with the sphygmograph on asylum patients. In nearly every case the sphygmogram was found to be abnormal. Acute mania is characterised by dicrotism, due to lax arteries, during the stage of great agitation. Mental depression enfeebles the cardiac action, and thus leads to diminished arterial tension. Epileptics generally have relaxed arteries and low arterial tension. During the *status epilepticus* and during the unconscious stage of the fit, the sphygmogram becomes monocrotic or dicrotic, and the pulse "soft, frequent, small, and running," as that of coma or collapse from acute disease. In general paralysis the pulse varies with the stage of the disease. The pulse-tracing of dementia indicates a feeble cardiac action and a slow circulation from imperfect fulness of vessels. In cases of arrested development of brain, the arteries were found to be tense, with strong cardiac systole, calling to mind renal disease and aortic obstruction.

SUICIDE OF A MEDICAL MAN SUFFERING FROM TYPHOID FEVER.

The Exeter Evening Post of Saturday last gives the sad particulars, elicited at an inquest, touching the death of Dr. Morris Hannigan Curtin, one of the medical staff of the Exeter Medical Aid Association. On the Saturday preceding he first complained of being ill. On the Tuesday following he felt better and performed his usual duties. On the Wednesday he was worse, and had a high temperature. Mr. Barstow, one of the non-resident officers, suspected typhoid, and called in Dr. Davy, who seems to have confirmed the diagnosis, though other particulars are not given in the report. Mr. Barstow kindly had Dr. Curtin removed from his lodgings to his own residence, thinking that he would have better attention. Dr. Davy saw him on the Thursday and Friday, and on both days found him in good spirits and comfortable, only regretting his distance from home. On the Friday he saw Father Hobson, who found him wandering in mind. Shortly after his visit Mrs. Barstow heard and saw him making for the surgery, where he shut himself in, and was shortly after found with a bottle containing liquid near him, gasping, bleeding at the nose, and the heart

Digitized by Google

scarcely beating. The breath had the odour of prussic acid. In spite of the injection of ether, artificial respiration, and the use of the stomach pump by Dr. Roper, he died in about twenty minutes, and the jury properly returned a verdict of "Suicide while in a state of unsound mind." Dr. Roper said it was not unusual for persons with typhoid to suddenly develop a suicidal mania. It is not, perhaps, quite so common, however, to see so much method in suicide in typhoid as was shown in this very sad case.

SALICYLIC ACID USED FOR ADULTERATION.

A COMMISSION appointed by the French Academy of Medicine to inquire into the employment of salicylic acid as an antiputrefactive agent in the manufacture of beers and wines has recently issued its report. Though this addition to beers and other eatables to ensure their keeping has not at present been the subject of legal proceedings in England, yet, as the report remarks, there is no evidence to show whether this is due to the tacit tolerance of the analysts or the fact that the acid is not used in English beers, which are more capable of preservation owing to their greater alcoholic strength. The inquiry divides itself into two parts. First, Has salicylic acid, in moderate doses continued for a long time, any deleterious effect on the body? Secondly, Is there a point in the percentage of the acid in beers and wines beyond which it is unsafe to go, and below which there is no danger to the consumer? The first question is answered in the negative. Despite the fact that Kolbe took for thirteen months one gramme every day in beer or wine, and that Lehmann gave fifty centigrammes a day to two individuals in sound health, without effect, there is reason to believe that the acid would be injurious in those predisposed to its action, and in persons not in sound health, especially those suffering from renal disease, in whom, as has been known for some time, owing to defective elimination, the drug quickly produces toxic symptoms. The answer to the second question is also unfavourable to the supporters of salicylage. Owing to the difficulty of ensuring an exact percentage and the ease with which a maximal dose can be passed without detection, it is unadvisable to sanction by law any addition of this nature. Moreover, as has been well said, Let each put salicylic acid in his beer if he likes, but not in that of others without their knowledge.

MEDICO-LEGAL REFORM IN PORTUGAL.

THE Society of the Medical Sciences of Lisbon is very anxious to obtain a radical reform in medico-legal matters, and at its last meeting, under the presidency of Professor O. Feijão, discussed the best mode of drawing up a satisfactory scheme. The Minister of Justice, who was present, thanked the Society for the steps it was taking, and promised to be present at future meetings for the discussion of the subject. The Society appointed a small committee, consisting of Señhores Bettencourt Raposo, Sousa Martins, and Silva Amado, to consider the subject and to draw up a report.

ENTOZOA AND PERNICIOUS ANÆMIA.

DR. G. REYHER, writing on the etiology of pernicious anæmia, points out that, as in a large number of these cases a Bothriocephalus latus has been diagnosed and expelled by means of male fern, the patients subsequently recovering, and as the anæmia of miners is now known to be due to the Anchylostomum duodenale, it is possible that all cases are due to entozoa of one kind or another, and that therefore diligent search should always be made in the fæces for the ova of tæniæ, &c. The treatment will in cases of successful search be obvious.

THE GUY'S HOSPITAL FUND.

THOUGH the sum contributed to the Guy's Fund (over £30,000) is still far short of what is needed, enough is already secured to raise hopes that the whole will be forthcoming. The letter of Mr. Money Coutts, forwarding the generous subscription of £1000, is in the right spirit and strikes the right note. "Hospitals are a permanent boon to the poor." So they are; and what a gain they are to the rich in the skilled surgeons and physicians they educate! We hope to hear of many more gifts like that of Mr. Money Coutts. But is it past hoping for that we may see in this *annus mirabilis* another Guy, whose generosity will build and endow an institution like that in the Borough, where poverty and sickness for generations to come may find a bed and all the amenities of medicine and surgery? The wealth of the nineteenth century is greater beyond all comparison than that of its predecessor? Shall it be used less magnanimously?

THE PREVALENCE OF HYDROPHOBIA.

A CONTEMPORARY comments on a case of alleged hydrophobia in a man named Mullett, at Bolton, who had been bitten three months before by a terrier, which is stated to have remained healthy until destroyed three months after biting the man. The wound was sucked and cauterised at the time. This case and another recent case at Putney are thought to be inconsistent with the axiom that rabies is always fatal to animals, and, according to Pasteur, fatal within ten days. An inquest was also held on a case of hdrophobia at Hindley in a woman bitten ten weeks before her death by her fox terrier; and another mad dog is reported to have been killed at Bolton after biting several children. Our contemporaries do good service in recording minutely all alleged cases. We may hope to see the provinces take a serious view of this question and help those who are seeking some protection to the public from a terrible risk.

MARGARET-STREET INFIRMARY FOR CONSUMPTION.

SOME difference of opinion appears to exist amongst the governors of the Margaret-street Dispensary for Consumption and Diseases of the Chest. A large majority of the medical men attached to the hospital object to a small minority of their colleagues practising what is called homœopathy. At present a breach exists, and this cannot be rectified until the special general meeting has decided what course is to be pursued. The Executive Committee have already given effect to their opinion. They considered that the minority should give way to the majority, and resign their posts or desist from the practice of homœopathy. Amongst the governors there are certainly two camps. It seems that the constitution gives the executive committee no legal powers in the circumstances. It is perfectly certain that the majority of the medical staff will resign unless the special general meeting endorses the action of the executive committee.

DEATHS OF EMINENT MEDICAL MEN ABROAD.

THE deaths of the following eminent continental medical men have recently been announced:—Dr. Fedele Margary, chief surgeon of the Hospital of San Giovanni Battista in Turin, and editor of the *Archivo di Ortopaedia*. Professor Dr. Halla, the well-known clinical teacher of Prague, in his seventy-fourth year; he had been editor of the *Prager Vierteljahrschrift* since the year 1843. Dr. J. Kalt, one of the most esteemed members of the profession in Bonn; he was a "Sanitätsrath." M. le Dr. Charles Saraxin, formerly agrégé of the old French Faculty of Medicine of Strasburg.

Digitized by Google

Dr. José Pereira Reis, Emeritus Professor in the Medical School of Oporto, and author of several medical and scientific works in Portuguese especially dealing with materia medica and prescriptions; he left a considerable legacy for the foundation of a children's hospital.

TRANSPORT AND TREATMENT OF INFECTIOUS PATIENTS IN THE METROPOLIS.

SIR VINCENT KENNETT-BARRINGTON has addressed to *The Times* a letter pleading for the free admission of all classes of patients into the hospitals of the Metropolitan Asylums Board, and for the general use of the Board's ambulances to the exclusion of all other vehicles. These proposals meet with our cordial approval. From an administrative point of view, we believe it is the only system which will ensure the perfection of the metropolitan machinery for the isolation of cases of infectious disease. But when the writer quotes statistics to show that hospital treatment has conferred upon London the benefit of reducing the amount of prevalence of these disorders, he exposes himself to some criticism. The diminution of the death-rate from scarlatina, which has undoubtedly been taking place for some years, is not confined to London, and other circumstances besides those of hospital provision are probably concerned in the reduction of this malady. As to small-pox, the less said about hospital treatment of the disease by those who are in favour of the London practice, the better. London, which treats the vast majority of its cases in hospital, has suffered out of all proportion to the rest of the country.

HOW LONG SHOULD A NERVOUS PATIENT BE TREATED?

THE question of how long treatment should be continued in a neurotic case when no evident benefit is produced has recently been raised in a Hamburg law court. A medical man, having as a patient a merchant suffering from "nervousness," treated him by galvanism. Altogether he galvanised him 445 times, but the nervousness did not disappear. Then came the matter of fees. The sum claimed was £111 5*s*.. The merchant disputed this on the ground that the treatment ought not to have been continued so long, as it was not producing any benefit. The court referred the matter to the medical board, which gave as its opinion that the doctor ought to have asked the patient after some fifty sittings whether he would like to continue them, as it was doubtful whether the treatment was doing any good. The court, however, declined to accept this view, holding that it was for the patient to say when he had tried the treatment as long as he was disposed to pay for, and so gave judgment for the full amount claimed.

THE PROPOSED MATERNITY HOSPITAL FOR BRISTOL.

THE scheme for the establishment in Bristol of a maternity hospital is exciting sharp local controversy. The erection and endowment of such an institution as a jubilee memorial is being earnestly advocated, and equally as earnestly opposed. A memorandum, expressing the opinion that a maternity hospital is much needed for the poor of Bristol, and would supply a long-felt want in the city, has been signed by all the members, with one exception, of the medical staffs of the three great Bristol medical charities and by other local medical men, and in the face of such a statement it will be well-nigh impossible to maintain that there is no need for such an institution. Many, however, of those who signed the memorandum referred to do not support the scheme as a jubilee celebration, and differ widely in their opinions as to how, should such a hospital be established, the best result may be obtained; so that it is doubtful whether, after all, the opponents of the scheme may not, for the present at least, prove successful.

METROPOLITAN HOSPITAL SUNDAY FUND.

AN important meeting of the Council was held at the Mansion House on Thursday, under the presidency of the Lord Mayor. A letter from the Bishop of London was considered, suggesting an alteration in the Sunday for the collection; but as all churches have now made their arrangements for the year, it was thought impossible to change the day. A special committee was appointed, on the lines of that proposed last year by the late Dr. Wakley, to consider the best means of promoting the success of the Hospital Sunday Fund, with special reference to the Jubilee of Her Majesty's reign. Incidentally Mr. Carr-Gomm made a statement showing that the London Hospital, of which he is treasurer, has not lost a single private subscription since the establishment of the Hospital Sunday Fund. Mr. Burdett adduced facts to the same effect.

THE SICK POOR OF ALL ENGLAND AND THE HOSPITALS.

MR. HENRY C. BURDETT in the daily press propounds a huge scheme for bringing the sick poor in every hamlet in the land into practical touch with every hospital, and the highest medical and surgical skill, through the Hospitals' Association. Every parish, congregation, village, or hamlet is invited, through its clergyman, minister, or other representative, to affiliate itself to this Association by the formation of a hospital society. The Hospitals' Association would thus be an immediate aid society, and its office a bureau of information and centre of reference. The scheme is to be discussed at a congress in May next, to be presided over by Sir Andrew Clark. The only question is, Is it not too big—too central? Have we got so well in hand the problem of the maintenance and management of metropolitan hospitals that London men should assume a kind of providence over the provincial sick and invite them up to fill our London hospitals? This is a practical and urgent question. Mr. Burdett is a wonderful organiser, but we think he would do well to leave the provinces to look after their own sick poor and hospital administration, and devote his great energies to the metropolitan institutions.

EMMENAGOGUE ACTION OF OXALIC ACID.

DR. POULET (*Gazette Hebdomadaire*, 1886, No. 20) extols oxalic acid as the best of all emmenagogues. It does not, however, he admits, abolish the pain experienced by many women in the discharge of the menstrual function, and it is of course, inoperative in amenorrhœa consequent upon organic disease. The dose in which he prescribes it is one teaspoonful every hour, of a mixture containing thirty grains of oxalic acid, about six ounces of water, and two ounces of syrup of orange-peel.

INFLUENCE OF TIME ON COLOURATION OF WINE.

ACCORDING to the observations of M. Cazeneuve, the aniline dyes—fuchsine, Bordeaux red, purple red, &c.—employed in colouring wines may persist for many years in certain wines, and be obtained intact therefrom by analysis. The chemical changes that wines undergo, especially in the *dépouillement* (stripping) of new wines, lead to the precipitation of a greater or less amount of the artificial colouring agent. The diseases produced by microphytes (e.g., *mycoderma vini* and *aceti*) also cause a disappearance of colour.

PYÆMIA AFTER EXTRACTION OF A TOOTH.

DR. ZAWADSKI mentions in a Polish journal a case where the extraction of a lower wisdom tooth in a man, aged forty-six, by a "feldsher," was followed by a fatal result. The day after the operation the soft parts in the neighbourhood began to swell, then followed severe headache, a rigor, and fever, death occurring on the nineteenth day. At the necropsy, purulent inflammation of the dura mater of the base on the left side was found, and purulent thrombi in the cavernous and superior petrosal sinuses. The soft parts near the angle of the lower jaw were infiltrated with pus, and there were broken-down thrombi in the neighbouring veins, also metastatic abscesses in the lungs and spleen.

ANOTHER POST-GRADUATE COURSE.

FOLLOWING in the wake of America, Edinburgh, and Manchester, where the movement has been attended with remarkable success, an arrangement has been made by the staff of the Leeds General Infirmary, under which a course of lectures and demonstrations will be given weekly to qualified practitioners. The first lecture of the course was delivered by Dr. Clifford Allbutt on the 21st inst. on "Coma and its causes."

SEVERAL of the local boards in the Halifax district have recently decided to have medical officers of their own, instead of joining in the payment of one medical man for the whole district. The Local Government Board have, however, decided that the combination shall continue, and this decision is meeting with considerable opposition throughout the district affected.

FOR an alleged libel published in *Life* on June 6th, Mr. Tom Bird has, through his solicitor, obtained from the magistrate sitting at Bow-street Police Court summonses against the proprietor and publisher of that newspaper.

A Professorship of Hygiene has recently been created at Breslau, to which Professor Flügge of Göttingen has been appointed, where he is Director of the Institute of Chemistry and Hygiene.

WE hear that Dr. Ralph Leslie, who accompanied Sir F. W. de Winton up the Congo, has started with Mr. Stanley on the Emin Pacha Expedition.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5640 births and 4043 deaths were registered during the week ending Jan. 22nd. The annual death-rate in these towns, which had been equal to 26·5 and 24·1 per 1000, further declined last week to 22·8. During the first three weeks of the current quarter the death-rate in these towns averaged 24·5 per 1000, and exceeded by 0·4 the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·0 in Derby, 15·2 in Norwich, 15·6 in Brighton, and 18·2 in Birkenhead. The rates in the other towns ranged upwards to 28·4 in Leeds, 30·1 in Manchester, 32·7 in Preston, and 33·8 in Plymouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 475 and 485 in the preceding two weeks, declined last week to 392; they included 146 from measles, 92 from whooping-cough, 62 from scarlet fever, 36 from diarrhœa, 33 from "fever" (principally enteric), 23 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded during the week in Birkenhead, Bolton, or Halifax; whereas they caused the highest rates in Preston, Leeds, and Huddersfield. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Wolverhampton, Liverpool, Leeds, and Huddersfield; from whooping-cough in Leeds, Manchester, Norwich, and Huddersfield; from scarlet fever in Norwich, Sheffield, and Plymouth; and from "fever" in Cardiff. The 23 deaths from diphtheria in the twenty-eight towns included 13 in London, 2 in Portsmouth, 2 in Liverpool, 2 in Manchester, and 2 in Preston. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. Only 4 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 731 and 591 in the preceding two weeks, further declined last week to 531, and were 5 below the corrected average. The causes of 93, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Portsmouth, Brighton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 29·9 and 26·1 per 1000 in the preceding two weeks, further declined to 23·7 in the week ending Jan. 22nd; this rate exceeded, however, by 0·9 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 9·7 and 15·8 in Perth and Leith, to 27·7 in Glasgow and 30·8 in Paisley. The 591 deaths in the eight towns last week showed a further decline of 61 from the numbers in the previous two weeks, and included 20 which were referred to whooping-cough, 16 to scarlet fever, 8 to measles, 8 to diphtheria, 7 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), and 1 to small-pox; in all 65 deaths resulted from these principal zymotic diseases, against 94 and 72 in the preceding two weeks. These 65 deaths were equal to an annual rate of 2·6 per 1000, which was 0·4 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 27 and 26 in the previous two weeks, further declined last week to 20, of which 14 occurred in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The deaths from scarlet fever, which had been 13 in each of the preceding two weeks, rose last week to 16, and included 9 in Glasgow, 3 in Aberdeen, 2 in Edinburgh, and 2 in Paisley. The 7 deaths attributed to diarrhœa showed a further considerable decline from the numbers in recent weeks, as did the 8 fatal cases of measles, of which 7 occurred in Glasgow. The deaths from diphtheria, which had been 12 and 5 in the previous two weeks, rose again last week to 8, all of which occurred in Glasgow. The deaths referred to "fever," which had been 7 in each of the previous two weeks, declined last week to 5, of which 2 occurred in Edinburgh, 2 in Dundee, and 1 in Glasgow. The death classed to small-pox was said to be a fatal case of chicken-pox in Leith. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 213 and 181 in the preceding two weeks, further declined last week to 165, but exceeded the number in the corresponding week of last year by 5. The causes of 70, or nearly 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 31·3 and 36·2 per 1000 in the preceding two weeks, declined again to 32·2 in the week ending Jan. 22nd. During the first three weeks of the current quarter the death-rate in the city averaged 33·2; the mean rate during the same period did not exceed 23·7 in London and 23·5 in Edinburgh. The 218 deaths in Dublin last week showed a decline of 27 from the number returned in the previous week, and included 4 which were referred to scarlet fever, 6 to diarrhœa, one each to diphtheria, whooping-cough, and "fever" (typhus, enteric, or simple), and not one either to small-pox or measles. Thus the deaths from these principal zymotic diseases, which had been 13 and 21 in the previous two weeks, declined again last week to 13; they were equal to an annual rate of 1·9 per 1000, the rates from the same diseases being 1·9 in London and

Digitized by Google

14 in Edinburgh. The fatal cases of scarlet fever, which had been 6 and 8 in the preceding two weeks, declined last week to 4; and the deaths from diarrhœa, fever, and whooping-cough also showed a decline from the numbers in the preceding week. The deaths both of infants and of elderly persons were fewer than those in the previous week. Six inquest cases and 11 deaths from violence were registered; and 56, or more than a quarter, of the deaths occurred in public institutions. The causes of 45, or nearly 20 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

On the 20th inst. Surgeon-General J. Hendley, C.B., the principal medical officer at Aldershot, made the official half-yearly inspection of the Depôt (16th Division) Medical Staff Corps, which paraded under the command of Surgeon-Major Staples.

ADMIRALTY.—Staff Surgeon Eugéne Victor de Méric has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

The following appointments have been made:—Fleet Surgeon Thomas H. Atkinson, to the *Vernon;* Fleet Surgeon Fleetwood Buckle to the *Brilliant;* Staff Surgeon Solomon Kellett, to the *Cordelia;* Staff Surgeon Herbert M. Ellis, to the *Valorous;* Staff Surgeon Valentine Duke, to the *Calliope;* Surgeon Alexander W. M'Leod, to the *Invincible;* Surgeon Alfred Copley, to the *Calliope;* Surgeon A. M. Page, to the *Monarch;* and Surgeon G. Smith, to the *Hercules.*

ARTILLERY VOLUNTEERS.—3rd Durham: Surgeon and Honorary Surgeon-Major Joseph Frain resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.—1st Kent: Acting Surgeon G. H. Harvey, M.B., resigns his appointment.—1st Worcestershire: Acting Surgeon Henry Horton resigns his appointment.

RIFLE VOLUNTEERS.—3rd Surrey: Surgeon G. R. Barnes is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

THE UNIVERSITY OF LONDON AND ITS NEW REGULATIONS.

To the Editors of THE LANCET.

SIRS,—A recent regulation affecting the Intermediate Examination for the degree of Bachelor of Medicine has been issued by the University of London. As it is reasonably considered a hardship by many students who are preparing for the July examination, I desire to draw attention to it. The regulation (dated August 1st, 1886) is to come into force in July, 1887, and is as follows:—

"Candidates at the July examination shall be examined for a Pass or for Honours in each of the following subjects: (1) Anatomy, (2) Physiology and Histology, (3) Organic Chemistry; (4) Materia Medica and Pharmaceutical Chemistry. Every candidate for the July examination, on sending in his name for the examination, must state whether he intends to compete for Honours in any subject or subjects. No candidate shall be allowed to take both the Pass and the Honours papers in the same subject; but every candidate must take the Pass papers in those subjects in which he does not offer himself for Honours. A candidate who enters for but fails to obtain Honours in any subject may be recommended by the examiners for a Pass in that subject, if they are satisfied such a competent knowledge thereof as is required by the regulations for the Pass Examination, &c."

The effect of this new regulation, as far as I have been able to gather, will be altogether to cut out many men deserving of Honours from the competition for Honours. Why? Because few medical students can afford to risk rejection in any one subject which entails rejection on the whole examination. As it is, the curriculum is quite long enough; they have not the time, money, or inclination to prolong it. Many of those, therefore, who might have competed for Honours under the old regulations will now rest content with taking the Pass papers only, and, having so decided, will lower their standard of work accordingly. They will be supported in this course by a note appended to the above-quoted regulation, which reads thus:—"Candidates must bear in mind that the standard of attainment for the Honours Examination is *much higher* than that for the Pass Examination; and they should therefore exercise *due caution in making their choice,* to which they will be required to adhere" (the italics are mine). There appear to be two possible objects only to be attained by the new regulations. The first, that the examiners may be saved a little trouble, which is, I fancy, scarcely a valid one; and the second, that those students who present themselves for the Intermediate M.B. Examination "in due course"—that is to say, in two years after having passed the Preliminary Scientific Examination—may be practically excluded from the competition for Honours. It is only reasonable to ask, if the University of London aims at restricting the competition for Honours in any subject to specialists in that subject, that such should be definitely stated in the regulations. Specialists in even one of the four subjects of the Intermediate M.B. Examination are scarcely to be produced, under ordinary circumstances, in two years at a medical school.

I may mention, in passing, that a very general opinion appears to prevail that the whole system of competition for Honours at the University of London needs revision. At present there is nothing to indicate the relative standing in point of seniority of the competing candidates, and a man on his first attempt at an examination may be pitted in the Honours competition against, and beaten by, another several years his senior, who has tried the examination one or more times previously without success. Of the unfairness of the competition there will be no record: the result only will remain.

As regards the new regulations at the Intermediate M.B. Examination, however, I think you will agree with me that they are scarcely likely to satisfy the prevailing wish for revision. They tend either to encourage men to postpone the examination and prolong their ante-clinical studies, or to lower their standard of work. They are not likely to add popularity to the University of London examinations, which are already not too popular among students or teachers.

I am, Sirs, yours truly,

VINCENT D. HARRIS, M.D. Lond., F.R.C.P.,
Demonstrator of Physiology at St. Bartholomew's Hospital.
Wimpole-street, Cavendish-square, W., Jan. 1887.

THE PROPOSED JUBILEE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—The proposal to found another special hospital for the treatment of diseases of the throat, ear, skin, eye, rectum, &c., is not likely to meet with general approval. There already exists in London a number of special hospitals devoted to the treatment of these diseases, in addition to the facilities afforded by all the general hospitals. As a consequence, it is a notorious fact that many of the patients seeking relief at these special hospitals do not belong to the class of the indigent poor, for whose relief alone money is subscribed by the public. If, however, it is thought advisable to commemorate the Queen's Jubilee Year by the foundation of a Queen's Jubilee Hospital, there is a class of cases for which, it seems to me, hospital accommodation is required. I refer to cases of chronic but curable diseases, such as spinal abscess, diseases of joints, suppuration of joints, &c. Although cases of spinal abscess, especially in adults, were formerly practically incurable, we have now ample evidence that, if the cases are treated strictly aseptically from first to last, a very large proportion will recover completely. Unfortunately the time required for cure is long, on an average eight to ten months, and sometimes much longer, and this lengthy treatment can only be carried out in exceptional cases and with great inconvenience in a general hospital. The aim of these hospitals is to do the greatest good to the greatest number, and if a considerable proportion of the beds is occupied for months by these chronic cases the efficiency of the institution is seriously impaired, and cases requiring urgent treatment have to be rejected for want of room. Hence one of two things usually happens. Either the cases are not admitted at all, the abscess is allowed to burst, and the patient ultimately loses his life from prolonged suppuration and its consequences

Digitized by Google

or, if the patients are admitted, they are only kept in and treated aseptically till the discharge becomes slight, and then they are dismissed and relegated to the out-patient department. In most of these cases the whole benefit of the stay in hospital is undone, and the patient goes steadily down-hill. For, however efficient the apparatus employed to give support and fixation to the diseased part, the home surroundings and hygienic conditions are as a rule wretched, and the food unsuitable in quality and deficient in quantity, while the patient as soon as he is discharged from the hospital may have to earn his living. And more serious than these are the risks to the continuance of strict aseptic treatment: the patient finds it inconvenient to come to the hospital on the day he is told, and the dressings are left on too long, or he finds the wound uneasy or itchy, and takes off the dressings with the view of giving relief; or when he comes to the hospital, especially if it be a large hospital, his wound is not dressed by the surgeon or the house-surgeon, but, it may be, by some dresser who has had insufficient experience of antiseptic work. For one or other of these reasons, when a patient is dismissed from hospital before his wound is completely and thoroughly healed, fermentation, as a rule, ultimately occurs, and he is very little better off than if he had never been taken in at all. I am constantly meeting with such cases, more especially in the case of children, where patients present themselves with septic and suppurating wounds who have been in other hospitals for some weeks, and have then been sent out to be treated as out-patients. I do not at all mean to imply that this is any fault of the surgeon in charge of the case, or of the hospital at which it was treated; it results entirely from the fact that in a general hospital one cannot allow any large number of beds to be occupied for an indefinite time by the same cases. It is no exaggeration to say that there is a pressing necessity for an institution where patients, provided their diseases are curable, can be kept as long as is necessary and treated strictly aseptically, and that if such an institution existed many lives would be saved which are now lost.

In speaking of spinal abscess it must not be supposed that I mean that that is the only or, indeed, the chief class of cases for which this sort of accommodation is necessary. It is equally required for other chronic but curable cases—as, for example, diseases of joints. The same remarks apply to advanced joint disease as to spinal abscess; and it may be added further that excision, which is not always good practice, would not be so often resorted to were it not that it is necessary to shorten the stay of these cases in hospital.

A great deal more might be said in support of this suggestion, but I think I have said enough to show why I hope that the energies of those who wish to promote a Queen's Jubilee Hospital may be expended in the direction which I have indicated, rather than on the foundation of a special hospital for which there is no public necessity.

I remain, Sirs, yours faithfully,

Welbeck-street, W., Jan. 22nd, 1887. W. WATSON CHEYNE.

THE TERM "SPAYING."

To the Editors of THE LANCET.

SIRS,—I cannot say much in respect of your critical research on this subject if you believe, as certainly is asserted in your article in THE LANCET of to-day, that the word "castration" is the analogue in the male for "spaying" in the female. It is not so; the proper word so to use is "gelding." Both these terms mean the removal of the essential sexual organs of immature animals to prevent the access of sexual maturity, and they both mean the double operation. "Castration" has no such meaning, and it may be either single or double. To apply this term to removal of the uterine appendages, as is done by the Germans, is an error in classics, but otherwise not very objectionable. The word "spaying" is, however, eminently objectionable, for it is entirely misleading. Whenever used, it at once conjures up the idea of masculine voice, the growth of a beard and other male peculiarities, as well as the loss of sexual appetite, not one of which is an incident in the complete after-history of a case of removal of the diseased uterine appendages from a mature woman. It is a term, therefore, which ought not to be used, as well for the other reason, which you so trenchantly point out, that it is one of reproach to the poor sufferers who have had to submit to it. There are many other and very strong objections to this unnecessary term which I have already urged and need not repeat here.

I am, Sirs, yours truly,

Birmingham, Jan. 22nd, 1887. LAWSON TAIT.

THE PETITION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS TO THE PRIVY COUNCIL.

To the Editors of THE LANCET.

SIRS,—Without attempting at present to give a detailed analysis or a final summing up of the signatures to this memorial received by us, we may state that up to date we have over 4000 names of Members of the Royal College of Surgeons appended to it, and that each post still brings in numbers of signatures in reply to our issue of copies of this petition. Already, therefore, you will see that our demand is most strongly backed up by Members of the College, and should have enormous weight with the Privy Council. Of course, however, we are still desirous of receiving additional names to add to the petition, though its success appears to us now assured. As our time is just now so much occupied in the reception and arrangement of these forms, perhaps you will excuse any further details for the present.

We are, Sirs, your obedient servants,

Jan. 26th, 1887. WARWICK STEELE, WM. ASHTON ELLIS, } Hon. Secs. Assoc. of M.R.C.S.

ARTERIAL PRESSURE.

To the Editors of THE LANCET.

SIRS,—Dr. George Johnson's letter is satisfactory so far as it explains one possible form of blood pressure—that produced in the large elastic arteries from constriction of the minute arterioles. But this does not cover the whole ground. In the first place, I do not understand Dr. Brunton to refer exclusively to the large elastic arteries when he states that tension and pressure are synonymous terms. On the contrary, I understand this expression as a universal one, applicable to all areas. Indeed, there are many passages where he distinctly implies so; as, for example, dilatation of the renal arterioles increasing the pressure in them. Are we to suppose, when constrictive impulses travel along the vaso-motor nerves, that the peripheral ends of the arterial system are contracted, and the pressure in them lowered, while the more central parts are dilated, and have their pressure increased? If this is the correct reading, how are we to understand the following statement at page 231:—"If the arterioles are made to contract, the pressure rises, but the increased pressure stimulates the vagus roots in the medulla." Surely the vagus roots would be affected by the arterioles, whose lumen is contracted and whose pressure is lowered; certainly not by any large elastic artery, where only is the pressure increased.

I remain, Sirs, your obedient servant,

East Greenwich, Jan. 25th, 1887. W. NICHOLSON.

TREATMENT OF THYROID CYSTS.

To the Editors of THE LANCET.

SIRS,—After reading a paper on the above subject at the Clinical Society on Jan. 14th, Dr. Felix Semon, who was present but did not take part in the discussion, mentioned to me that he thought someone had previously adopted the method of stitching the cyst wall to the skin; but as he could not give me more exact information without reference, he would write and tell me if it were so. The following information, to me quite new, which he was kind enough to communicate by letter, is so important that I feel I ought to ask you to give it publicity:—"I find on reference that the proposal was made, and acted upon, not less than thirty years ago by the younger Chelius (*vide* Chelius' 'Handbuch der Chirurgie,' vol ii., p. 463, 1857), and that it has been referred to since with approbation by Bardeleben and Lücke (in Pittra Billroth's 'Chirurgie,' Band iii., Abth. i., Lieferung 6, p. 83), and mentioned by myself in Heath's 'Dictionary of Surgery,' vol. ii., p. 619)."

I am, Sirs, yours truly,

Leeds, Jan. 25th, 1887. A. W. MAYO ROBSON.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

FOR the third time within a comparatively short period the College has lost by a sudden and unexpected death one of the members of its teaching staff. On Friday night last Mr. W. H. Waters, M.A., the senior demonstrator with Professor Stirling in the physiological laboratory, died in bed from what appears to have been an epileptic seizure. He had been at work as usual at the College in the afternoon, and his death has come as a great shock to all connected therewith. During the interregnum between Dr. Gamgee and the appointment of Professor Stirling, Mr. Waters had entire charge of the physiological department, delivering the lectures and superintending the work of the laboratories. Hulme Hall (the new hall of residence for students) was opened this month, where at present thirty students can be accommodated. The sanitary arrangements of the building have received special care and attention, and the comfort of the students, both in their studies and their amusements, has been well cared for. Under the will of the late Mr. A. Heywood, the College receives £10,000, which the donor desires shall be used, so far as the rules and regulations of the College will allow, for "the instruction of women and girls in the said College." As years roll on, it may be fairly expected that the different colleges of the Victoria University will become possessed of ample funds for carrying on the various branches of their work; it has but recently been announced that Mr. Harrison of Liverpool has given £10,000 to the Liverpool College to found a chair of Engineering there. The proposed application to the Government for a grant out of the Imperial exchequer on behalf of the Victoria University is receiving the support of most of the municipal bodies of this and adjoining counties.

HOSPITALS.

Amongst the hospitals, &c., benefited under Mr. Heywood's will St. Mary's comes in for £200. This time the Royal Infirmary receives nothing. From a return published for the six months ending Dec. 31st, it appears that the number of patients under treatment at the Infirmary and its allied branches, the Convalescent and Fever Hospitals, has been in considerable excess of those of the corresponding six months of the previous year. The largest increase has been at the Fever Hospital, where 914 patients have been admitted, against 569 in the foregoing year, owing to the great prevalence of scarlet fever during the past few months. At the three hospitals there has been a total increase of 713 in-patients and 2790 out-patients. At the Infirmary no special festivities were held at either Christmas or New Year tide, the authorities having apparently set their faces against anything of the sort during the last few years, though formerly some very pleasant entertainments were got up at these seasons. At the Children's Hospital, Pendlebury, at the Ancoats, the Clinical, and the Royal Eye Hospitals, entertainments were much enjoyed; the inmates of the latter hospital were mainly indebted to its indefatigable chairman, Mr. Alderman Goldschmidt, for their evening's feast and amusement. It is worthy of note how the various boards of guardians differ as to the supply of beer to the inmates of the workhouses at Christmas time; in Salford and Manchester no beer was allowed, whilst at Withington and Prestwich the adults were supplied with a pint each.

SOCIETIES.

The annual meeting of the Medical Society disclosed a satisfactory condition of the Society's affairs. Both financially and numerically it is flourishing. A proposal was alluded to of attempting to raise funds for the erection of a building of its own for the purposes of library and of meetings, but at present this project is deferred, and, indeed, seeing how well at present the Society is housed at the College, it would scarcely appear to be necessary. It seems to have almost passed into an unwritten rule now that the president should hold office for two years, and in accordance therewith Mr. Hardie was re-elected for the ensuing year. The Pathological Society continues to increase and flourish, and a very pleasant feature is the exchange of courtesies between this Society and that of Liverpool by the attendance (as has been the case recently) of members from the two cities at each other's meetings. The Medical Society might also well take a leaf out of its younger rival's book in the provision at its meetings of tea and coffee prior to the commencement of business.

Many of your readers will hear with regret of the ill-health of Mr. Scott, the genial and obliging secretary of the Manchester and Salford Association and its allied societies. A testimonial from a number of his friends who appreciate his services in connexion with the above was recently presented to him, in the shape of a purse of £100.

Manchester, Jan. 25th.

BIRMINGHAM.

(From our own Correspondent.)

POST-GRADUATE LECTURES.

YET another series of advanced lectures is advertised; this time under the auspices of the Medical Institute, on the subject of Bright's Disease. No one can have any excuse for not becoming acquainted with the modern views embraced in these courses of lectures—that is, if he can find time to attend them. What with work and worry the busy practitioner generally has his hands pretty full, and however he may be disposed towards the attainment of knowledge, he may reasonably ask, "Which of the learned, with all his love, hath leisure to be wise?"

A SUGGESTION FOR TEMPERANCE REFORMERS.

A novel suggestion has been made by an enthusiastic advocate of the temperance cause, the practical application of which, could it be carried out, might probably be productive of some good. He says: let a certain number of barmaids from various public-houses attend the casualty rooms of the hospitals, on Saturday nights particularly; when they will see for themselves the effects of drink and degradation in some of its worst phases. They will doubtless be stirred to higher motives in refusing to supply more drink to those who have evidently already had enough, and they will observe for themselves how missapplied in a given sense are the philanthropy and benevolence of those whose charitable aid supports these institutions and provides the best educated professional men and intelligent nurses to administer aid, not to the poor and deserving, but mainly to the debauched and debased through drink. Such is charity in its widest sense, and as such it knows no distinction between the thrifty and steady and the worst forms of social evils. Police-courts, on the other hand, take more note of human nature than charity. The contrast is worthy of attention.

DILAPIDATED DWELLINGS.

The so-called rookeries have ever been a subject of active condemnation on the part of the coroner, and a recent experience of his where the jury narrowly escaped tumbling through a rotten floor evoked a strong expression of regret that such tenements should be allowed to exist in crowded towns, where risks to life and limb, to say nothing of comfort, were so often conspicuous. Another oft-repeated and wise admonition on the part of the coroner will bear repetition—the treatment of

FAINTING AND SYNCOPE.

The common practice of raising fainting persons to a sitting or upright position is often sufficient to destroy the spark of life which remains. The death of an eminent statesman a short time ago gave opportunity to the coroner for emphasising this fact, and of pointing out how much more reasonable and sound it is to keep such persons in the prone position while restoratives and local means are adopted to enable them, if possible, to regain consciousness. Though inquiring into the cause of the appearance of the "shadow feared by man," the coroner is not unmindful that its advent is often preventable, and a due regard to the welfare of the living prompts him to give sage admonition as the result of his own experience of some frequent causes of death.

Birmingham, Jan. 27th.

THE annual meeting in connexion with the Newton Cottage Hospital and Dispensary was held on the 20th inst., when favourable reports were presented.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

CURIOUS CASE: ACCIDENT INSURANCE.

A CURIOUS case, bearing on accident insurance and the legal and medical definition of an accident, has just been tried before before Mr. Justice Cave at the Newcastle Assizes. The widow of a late hotel proprietor brought an action against the Northern Accident Insurance Company to recover £1000 due upon an ordinary policy in the company. The deceased, it was shown, was a healthy man, but two or three years ago he had suffered from diabetes, from which he had recovered, and it had nothing to do with his death. He was not, as far as was known, suffering from any disease at the time of his death. It appears that in May, 1886, he was in his bedroom alone, and while cutting his corn the knife slipped and cut his foot. The wound was painful, but the deceased did not consider it serious, and after five days of domestic treatment the foot got into such a state that medical assistance was called in, blood-poisoning set in, and death ensued. Evidence was called to show that death was caused by the accident named. His widow was not aware that at the time of his death he was insured in the company, and when the policy was found the claim was sent in. The defence was that death arose from mortification caused by diabetes, and that no notice of claim was sent in within the time specified in the policy; but the judge overruled this, saying that "this was a ground for a counter claim only." Mr. Justice Cave, in giving judgment, said "he had come to the conclusion that the cut on the foot which was spoken of did lead to the production of the sore, which degenerated into gangrene and produced blood-poisoning, and so death. Deceased's actual health was not so robust as that of some men; it seemed to him impossible to say that the diabetes alone could be said to have so contributed to his death, but that the injury alone could not have so contributed within the meaning of the policy it was also impossible to say. No doubt he was a man of irregular habits, but to go so far as to say he was intemperate was another matter. If insurance companies did not intend to be liable in these cases, they must at once introduce some conditions to strike at them." His lordship gave a verdict for the plaintiff for £1000, but as the case was one fairly admitting of argument and discussion, he consented to stay execution on £1150 being paid into court.

SOUTH SHIELDS VOLUNTEER LIFE BRIGADE.

The Volunteer Life Brigade of South Shields is well known for its deeds of mercy and of daring in connexion with shipwrecks at the mouth of the Tyne. The *Newcastle Daily Chronicle*, in an appreciative article, mentions that since the formation of the brigade 180 persons have been rescued by means of the rocket apparatus, and adds that during its existence the brigade has been honoured with the services of an honorary surgeon. The first gentleman who held the appointment was the late Dr. Stokoe, and he has been succeeded by Dr. J. R. Crease, who has since been unanimously elected annually. It may be mentioned that the appointment of surgeons to the brigade entails services of the most arduous nature and exposure to the very worst weather, for it is only at such times that medical services are needed.

BOROUGH OF TYNEMOUTH INFIRMARY.

It is now stated that the foundation-stone of the new building is fixed to be laid on the Jubilee day in June next, on land presented by the Duke of Northumberland. The building fund was opened only a month ago by a donation of 200 guineas from Mr. R. S. Donkin, the borough member, and it was much augmented by an Art and Industrial Exhibition held at Tynemouth about the same time.

NEWCASTLE INFIRMARY.

Owing to the length of my letter last week, I was unable to give you the recommendations of the special committee as to the future election of the honorary medical staff, and which will be duly appreciated by candidates:—"They desire to call attention to the very unsatisfactory method under which the election of the honorary medical staff is conducted. On the skill of these gentlemen the reputation and efficiency of the infirmary depend, yet their election is dependent on their skill as canvassers or the number of personal friends who canvass for them. This must always be the case when success depends upon securing a majority of the votes of a large body of subscribers who know little of the fitness of the applicants. The committee therefore recommend that in future all elections to vacant posts at the infirmary be placed in the hands of a committee of selection. Such committee might be the house committee or a special committee appointed for that purpose."

Newcastle-on-Tyne, Jan. 24th.

EDINBURGH.

(From our own Correspondent.)

DR. CLOUSTON ON SELF-CONTROL.

LAST week Dr. T. S. Clouston, Lecturer on Mental Diseases in the University, delivered an address on Science and Self-Control, under the auspices of the University White Cross Society. Viewing the subject from a purely scientific standpoint, and in the light of his large experience, the lecturer traced the relation of the reproductive functions to the general activities of the human economy in the various stages of life. The developmental phases of the question occupied the greater part of the address, and it was demonstrated in a most interesting way, from the evolutionary point of view, that the premature expenditure of energy in that direction results in racial deterioration, if not extinction. Numerous illustrations from the history of human and animal races were cited to show the wise checks and penalties ordained by Nature's laws for the preservation and elevation of her types. Dr. Clouston also stated a physiological law of the transformation of vital energy, accurately corresponding to that of the physicist, showing that the various physiological activities of man are correlative to, and to a great extent substitutional for, one another; the substitution of one form for any other less adapted to normal existence in its several phases being carried out by the will of the individual appropriately directed, or by the exigencies of his environment. This law of the conservation and transformation of vital energy was illustrated by reference to the very specialised manifestations of human activity produced by particular combinations of natural or fortuitous surroundings. The lecturer shortly and aptly pointed the moral to be derived from the scientific principle thus established. In addressing an audience of undergraduates, who in their turn must become the teachers and exemplifiers of healthy living, wherever their lives may be spent, he laid stress upon the importance of a due balance between the various forms of vital activity in human life, and showed how the possession of self-control supplied the only key to its attainment. Professor Chiene, who occupied the chair, warmly coincided in Dr. Clouston's views, and hoped that the able expression of them to which he had listened would be rendered permanently and widely useful by the publication of the address; a hope also expressed by Professor Calderwood, who supported the proposal of a vote of thanks to the lecturer.

EDINBURGH UNIVERSITY COURT.

At a recent meeting the Court adopted a minute expressing the deep sorrow and the great loss occasioned to the University by the death of Lord Iddesleigh, and directed that a copy of the minute should be sent to the family of the deceased earl. Lord Balfour of Burleigh was appointed one of the curators of patronage of the University for a term of three years. A number of appointments to examinerships in the Medical Faculty were then made. In Materia Medica, Dr. C. D. F. Phillips of London was appointed, in the room of Dr. Murrell; in Physiology, Dr. Noël-Paton takes the place of Dr. Caton; in Pathology, Dr. Sims Woodhead succeeds Dr. Sidney Coupland; in Surgery, Dr. James D. Gillespie has been succeeded by Mr. Watson Cheyne; and in Clinical Medicine, Dr. Byrom Bramwell by Dr. J. D. Affleck. These appointments are for a period of one year, but their occupants are eligible for re-election annually till a term of five years has been completed; and it is customary for them to retain office for that length of time. The University Court also recognised the courses on Pathology and Practical Pathology held by Dr. Alexander Bruce as qualifying courses in the University medical curriculum; and a similar recognition

Digitized by Google

was continued in the case of Dr. Peter Young's lectures on Midwifery, on his removal to new class-rooms.

PROPOSED CONVALESCENT HOME FOR FEVER PATIENTS.

A proposition is at present under consideration by the city authorities as to whether they cannot establish a convalescent home for patients treated in the city fever hospital. At present there are frequent cases of patients leaving the fever hospital recovered only so far as an early stage of convalescence, and it is felt that could care and good nursing be extended to these for a somewhat longer period, away from the fever wards, it would greatly enhance the usefulness of the institution. The City Assessor is to be consulted on the question.

Edinburgh, Jan. 25th.

DUBLIN.

(From our own Correspondent.)

DEATHS OF EMINENT MEDICAL MEN IN DUBLIN.

WITHIN the last few days two well-known practitioners have been taken away. One of these, Dr. Denham, an ex-president of the Royal College of Surgeons in Ireland, had for some years retired from practice; but Dr. Henry Kennedy, who succumbed on Monday last, was in active practice until his last illness. I trust next week to be able to refer at greater length to the last-named gentleman, whose loss is deeply regretted by a large circle of friends.

ACADEMY OF MEDICINE IN IRELAND.

At the last meeting of the Surgical Section of the Academy, Mr. Henry Fitzgibbon read a very interesting paper on a case of Trephining for Mastoid Disease, with Paralysis and Aphasia. The patient recovered perfectly, although before the operation death was imminent. In the discussion which ensued. Mr. Wheeler, who recommended the procedure in 1883, stated that by this operation the tympanum, mastoid cells, dura mater, and the temporo-sphenoidal lobe were successively exposed.

BRITISH MEDICAL ASSOCIATION.

The annual meeting of the Dublin branch will take place on Thursday, the 27th inst., when the following motions will be brought forward: "That the Council be requested to take such steps as may be necessary to bring before the various teaching bodies in Dublin the necessity of providing systematic instruction in pathology." "That quarterly meetings of the branch are essential for carrying on the work of the Association." A paper will also be read on "Medical and Hospital Reform in Dublin."

INQUIRY AT MERCER'S HOSPITAL, DUBLIN.

The Corporation inquiry into the alleged ill-treatment of the patient Farrell, in Mercer's Hospital, closed on Saturday. The committee came to the unanimous conclusion that Farrell had received proper care; that he had been supplied with proper food during his illness. They considered that the conduct of the matron was justified throughout, and that Mr. Newcomen's conduct to her was unjustifiable; that Farrell had not been ill-treated, and that he received the most anxious care and attention from Dr. Kennedy. The committees further report that on Aug. 4th Farrell's condition made it probable that he might at any moment be seized with paroxysms of homicidal or suicidal mania, and that he should therefore be put under proper restraint. With reference to the conduct of the matron, the committee were of opinion that there was absolutely no evidence that she had neglected her duties, but, on the contrary, abundant proof that she had discharged them efficiently. The committee finally report that in their belief the allegations made against the institution originated in a concurrence of trivial circumstances, and that the management of the hospital was effective and humane.

DUBLIN HOSPITAL SUNDAY FUND.

I regret to state that the collections made in aid of this excellent charity on the 14th of last November show a decided falling off as compared with the previous year. In 1885 the amount obtained came to £4468 5*s.* 8*d.*, and last year to £4158 0*s.* 3*d.*, or a decrease of £310 5*s.* 5*d.* It must, however, be stated that the collection in 1885 was the highest obtained since the fund was organised. It may be interesting to add that the total amount collected since 1874 amounts to £50,058 6*s.* 2*d.*

BITE FROM A MAD FOX.

Lord Doneraile, of Doneraile Court, county Cork, and his coachman were recently bitten by a tame fox, which was affected with rabies. Although his lordship had on his gloves at the time, yet it has been thought better to take every precaution, and he and the coachman have proceeded to Paris, to be placed under the care of Prof. Pasteur.

The death is reported at an advanced age of Dr. O'Connell, of Kilmallock. The deceased at one time was a surgeon in the British army.

John Bryan, M.D., of Pettigo, has been placed on the Commission of the Peace for the County of Donegal.

Dublin, Jan. 25th.

PARIS.

(From our own Correspondent.)

THE DISCUSSION ON RABIES.

THE discussion on rabies was resumed on the 18th inst., the interest in the question being so great that it was difficult to obtain standing-room even in the passages. M. Peter read particulars of two new cases, communicated to him since the last meeting, in which death had taken place from the paralytic form of rabies after the intensive inoculations. A stonemason and his son were bitten on Nov. 8rd by a mad dog, and were treated in Paris from the 7th to the 21st of the same month. On Dec. 2nd the father was seized with violent pains at the seats of the inoculations in the head, the loins, and the limbs, and with general prostration. On Dec. 7th he had complete paraplegia with anæsthesia, or rather painful analgesia, as the pains were still felt in the limbs. There was no difficulty of deglutition, delirium, or convulsion, but slight hallucinations of hearing the day before his death, which took place on the 8th. These cases of paralytic rabies continue to occur, said M. Peter, and yet the partisans of the intensive method still ignore its dangers. The cases are explained away either by the doctrine of limitation or by attributing the death to some pathological condition, such as uræmia. The child, who was said to have died from uræmia, had not even had his play interfered with by the headache that always precedes a fatal termination. He had had neither eclampsia, coma, nor delirium. He had had dyspnœa and difficulty of deglutition, symptoms referable to the pneumogastric and glosso-pharyngeal nerves; and these, it must be recollected, have their origin in the parts of the nervous centres affected in rabies. The death of the man at Constantine had not been put down to uræmia, but no one knew exactly what he had died of. In the six cases brought forward the incubation had been from thirty-six to thirty-nine days, and death had occurred from paralysis, whereas ordinary rabies occurs after forty days, and is convulsive. M. Brouardel had quoted M. Von Frisch. It should be known that the Viennese Professor of Bacteriology had been sent to Paris on behalf of a committee of ladies interested in Pasteur's experiments, and that his sympathies were all in favour of the method; but when asked on his return what was his impression, he replied diplomatically, "I think that it is well to continue the investigation." The first ten conclusions of his report of his subsequent experiments were favourable to M. Pasteur's method, and were quoted by M. Brouardel in his last communication to the Academy; but the other six conclusions were absolutely condemnatory of it (see THE LANCET, p. 50). Consequently, both clinically and experimentally, the intensive method was dangerous—unlike the first method, which, if inefficacious, was at least harmless. As long as Pasteur's experiments remained purely physiological, they deserved the greatest praise and admiration; but the line must be drawn at the point where they are applied to human medicine. The anti-rabic inoculations originated in the following conception: Was it not possible to prevent the ulterior appearance of rabies by inoculation during its incubation with an attenuated virus, similar to those which had already been obtained for

Digitized by Google

other diseases? For his previous attenuated viruses M. Pasteur had made microbic cultures in bouillon, the attenuation being obtained by the action of oxygen through time. But this method was not applicable to rabies, the microbe of which was unknown. The ingenious idea occurred to him of passing the virus through a succession of living organisms, and it was found that the virulence of the monkey vaccine, so obtained, was attenuated, whereas that of the rabbit was intensified. This intensified virus was found to be attenuable by exposure to air, and M. Pasteur was able to obtain a series of decreasingly virulent viruses, the progressive inoculation of which, beginning with the weakest, prevented the appearance of rabies after infection with the most virulent. Thanks to this "Mithridatisation," a dog could be made refractory to rabies, and, what was even more extraordinary, a dog already bitten could also be rendered incapable of developing the disease. At this juncture a young man who had been badly bitten by a mad dog (J. Meister) offered to make a trial of the method. The case was delicate, but, after consultation with MM. Vulpian and Grancher, the treatment was applied, and four months later the result was made known to the scientific world, and it was proclaimed by M. Vulpian that a certain remedy had been found for hydrophobia. What had been the results of the method during the last year? In his article upon "Rabies" in the Encyclopædic Dictionary, M. Brouardel gave *thirty* as the average annual mortality for twenty-seven years in France. This was exactly the number of deaths for the last year—sixteen not inoculated, fourteen inoculated. After a fresh protest against the intensive method, M. Peter said: "I must be moved by a profound conviction to come here to discuss a treatment that has been adopted by the most eminent representatives of French medicine, and so risk my popularity and the sympathy of the Academy, which I prize above all. If I do so, it is because the new method seems to me not only dangerous, but rash, and I cannot help saying to M. Vulpian, *à propos* of his enthusiastic speech at the Academy of Sciences, 'What! you, an experienced physician, and a member of the Academy, did not understand that a single case proves nothing in therapeutics! You could not see that the patient had the same five chances out of six that we all have of escaping rabies after a bite from a mad dog! Why proclaim with enthusiasm what should have been made the subject of sober examination? Why conclude so hastily from the laboratory to clinical application? An eminent physician like you should have dissuaded rather than encouraged M. Pasteur, and I do not hesitate to declare that the words pronounced by M. Vulpian might compromise the Academy of Sciences, M. Pasteur, and M. Vulpian himself.'"
